School of Computing, DIT University, Dehradun, India[3]

Abstract*—Genetic Algorithm (GA) is an excellent optimization algorithm which has attracted the attention of researchers in various fields. Many papers have been published on works done on GA, but no single paper ever utilized this algorithm for misbehavior detection in VANETs. This is because GA requires manual definition of fitness function and defining a fitness function for VANETs is a complex task. Automating the creation of these fitness functions is still a difficulty, even though studies have found several successful applications of GA. In this study, a neuro-genetic security framework has been built with ANN classifier for detecting misbehavior in VANETs. It leverages a genetic algorithm for feature reduction with ANN as a dynamic fitness function, considering both node behaviors and contextual GPS data. Deployed at the Roadside Unit (RSU) level, the framework detects misbehaving nodes, broadcasting alerts to RSUs, Central Authority and the vehicles. The ANN based fitness function has been employed in GA that enabled the GA to select the best results. The 10- fold CV used enabled the whole system to be unbiased giving a precision accuracy of 0.9976 with recall and F1 scores as 0.9977, and 0.9977 respectively. Comparative evaluations, using the VeReMi Extension dataset, demonstrate the framework's superiority in precision, recall, and F1 score for binary and multiclass classification. This hybrid genetic algorithm with ANN fitness function presents a robust, adaptive solution for VANET misbehavior detection. Its context-aware nature accommodates dynamic scenarios, offering an effective security framework for the evolving threats in vehicular environments.

Keywords*—*VANET security; genetic algorithm; ANN fitness function; misbehavior detection; hybrid detection

I. Introduction

Modern technology advancements and high transportation expectations have caused the global automobile utilization rate to rise quickly [1]. The transport industry is dealing with a variety of issues due to the quick rise in the number of automobiles and the limited space in the infrastructure of roads, including a spike in traffic accidents, prolonged traffic jams, damage to public property and human life, etc. To address these issues and improve the efficiency of the transportation sector, Vehicular ad hoc networks (VANETs) emerged as a particular kind of mobile ad hoc network (MANET) [2] in which mobile nodes are vehicles such as cars, trucks, buses, and motorcycles etc. Vehicles follow the design of the road, corresponding to traffic regulations and flow restrictions rather than moving at random. Vehicles exhibit different speeds, and their movement and their behavior are impacted by the traffic signals, road signs, and other vehicles. The density of these networks or topology of these networks varies very rapidly, depending on the area, the time of day, and recent occurrences (like traffic jams or accidents) [3].

Around the year 2000, Vehicular Ad-hoc Networks (VANETs) were the subject of investigation for many research laboratories [4]. VANET was first used to improve road traffic safety and lower the number of accidents and traffic jams [5]. Today it covers numerous integrated services employing other technologies in addition to the basic functionality provided by VANET architecture, indicating a significantly wider application [6].

As shown in Fig. 1, the key constituents of VANETs are typically Trusted Authority (TA), Roadside Units (RSUs), and Onboard Units (OBUs). As the only component in a VANET that can be completely trusted, TA oversees monitoring the whole setup and changing the parameters for the other components. RSU, on the other hand, is set up along roadsides as wireless infrastructure to link cars to TA. Every vehicle has an OBU, a wireless device that processes, transmits, and receives messages (such as road status, condition, and so on) from other cars [7]. Vehicles can communicate with each other through vehicle-to-vehicle (V2V) communication in VANETs as well as with infrastructure through RSUs through vehicle-to-infrastructure (V2I) communication. Every vehicle in the VANET transmits data messages and safety messages every 100 to 300ms to the vehicles in range in accordance with dedicated short-range communications (DSRC) requirements [8]. The transmission of data and safety-related information by vehicles in an open-access setting creates security and privacy challenges for VANETs. If appropriate precautions are not taken, attackers may utilize user information to launch a variety of attacks that might be harmful to the network and its users.

Predictable mobility patterns, a large network size, frequent disconnections, a high rate of topology changes, and strict delay constraints are only a few of the distinguishing characteristics of VANETs that make it extremely prone to a variety of misbehaviors. Even though VANET research has been ongoing for more than a decade, there are still many open challenges, including ineffective QoS, uneven flow traffic, security and privacy concerns, poor resource utilization, and inefficient information distribution [9].

Additionally, there is need to apply various contextual information to enhance the ability to differentiate between nodes that are genuinely malicious and those that exhibit anomalous behavior for contextual reasons. Fig. 2 provides a great illustration of misbehavior scenario in VANETs. The vehicle v1 drops packets in both scenarios, leading most of the current security systems to treat it as a misbehaving node without doing any more research. But taking a closer look at the setting in which packet loss occurs in, it is found that in case (a), v1 drops packets likely due to the busy channel; in case (b), no external factor prevents it from forwarding those packets, indicating that v1 is acting maliciously. This example makes it abundantly evident that context could be crucial in identifying misbehaving nodes in VANETs.

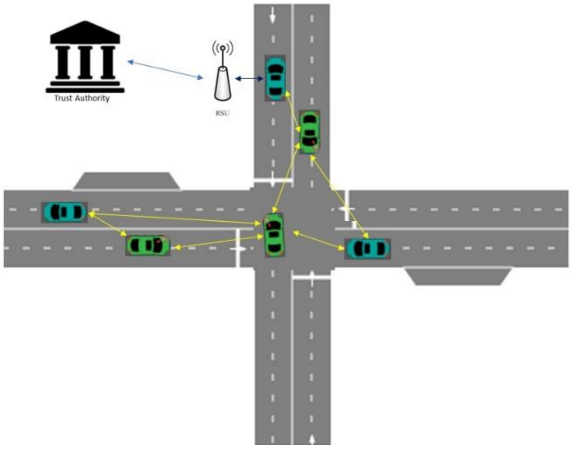

Fig. 1. Structure of VANET.

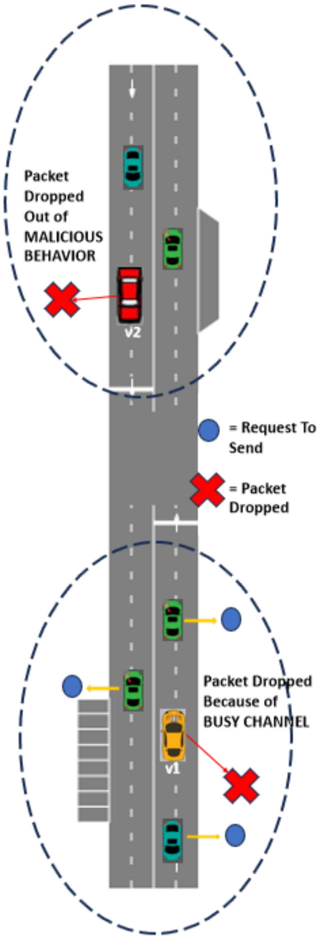

Fig. 2. Misbehavior example scenario.

In this paper, a context aware framework is proposed for detecting misbehavior in VANETs. In the proposed framework, both node behaviors (taken from BSM messages) and contextual information (taken from GPS data) are represented as features in the feature vector to train a genetic algorithm, with an artificial neural network (ANN) serving as its fitness function. The genetic algorithm takes the feature vector as input, dynamically reducing features based on ANN accuracy, and subsequently classifies whether a node exhibits malicious behavior. This hybrid genetic algorithm could offer a solution by combining the strengths of genetic algorithms, which excel in optimization and exploration of solution spaces, with ANN, creating a more dynamic and effective security framework for VANETs.

The main contributions of the study are to:

- Propose a security framework for misbehavior detection for VANETs using hybrid genetic algorithm with ANN fitness function.
- Compare multiple ML algorithms to be used as fitness function for genetic algorithm for better misbehavior detection.
- Compare the proposed framework with the existing ones for evaluation of the results.

Section II of this paper presents the overview of the existing works done in the field; Section III presents the proposed framework, including the communication architecture and the processing steps. Section IV discusses the simulation setup and results that include a comprehensive exploration of the framework, and a series of experiments that demonstrate the framework's effectiveness in detecting misbehaviour across a range of scenarios. Furthermore, it provides evidence of the framework's superiority over traditional machine learning models and existing misbehaviour detection methods, underscoring the critical role of context-awareness and the ANN-based fitness function in VANET security. Section V presents the discussion of the results, and the conclusion of the paper is provided in Section VI.

II. Existing Works

Over the past years, several security methods have been investigated to identify and address these misbehaviors in VANETs. The proposed Trust-Based Event Detection Algorithm (TB-EDA) compares the trust values of the neighboring cars of a node with the threshold trust value measured to identify misbehaviors [10]. In study [11], the authors introduced the Vehicular Reference Misbehavior dataset (VeReMi) to assess various misbehavior detectors. They also assessed different detectors on their datasets using metrics such as precision and recall. While misbehavior detection systems based on rules or specifications can provide security against known attacks, they lack the ability to identify unknown attacks.

To enhance robustness against Sybil attacks in VANETs, [12] proposed anonymous authentication and Sybil attack detection protocol. In a broader framework employing subjective logic, [13] improved two position verification mechanisms for misbehavior detection. The ML-based

Intrusion Detection System (IDS) proposed in [14] focuses on thwarting spoofing attacks using a probabilistic cross-layer approach in a VANET consisting of Electric Vehicles. The research in [15] presented SVM-based IDS for VANETs, incorporating an enhanced penalty function to strengthen the classifier's regularization. The study in [16] suggested ML-based IDS for VANETs, where XGBoost demonstrated superior performance in binary class and multi-class classification problems. The research in [17] introduced a data-centric approach to identify position falsification attacks, employing machine learning (ML) algorithms. The proposed method combines information from two consecutive Basic Safety Messages (BSMs) for both training and testing purposes.

The majority of these security solutions use one or more pre-established, predefined thresholds to identify abnormal nodes from regular ones. However, it is not possible to determine a single set of thresholds that perform effectively in every situation due to the very dynamic nature of VANETs. However, as the use of machine learning solutions for misbehavior detection is rising, the studies have showcased more dynamic and adaptive approaches for VANETs. But there is still a gap: there are limitations of traditional machine learning approaches in handling the dynamic and complex nature of VANET security. While machine learning has shown promise, it may struggle with the rapidly changing and unpredictable nature of vehicular environments and the ever-evolving threats. It is proposed that hybrid algorithms could fill this gap by introducing a more adaptive and robust approach by combining the best of two or more algorithms for identifying the border between normal and misbehaving nodes automatically.

III. Proposed Framework

A. Proposed Architecture

Fig. 3 presents the communication architecture of the proposed framework. Most studies of misbehavior detection in VANETs applied misbehavior detection in On Board Units (OBUs) of individual vehicles. Keeping in mind that the communication range of RSUs is much broader than the communication range of vehicles [18], in the proposed scheme, our detection framework will be deployed at the RSU level. RSUs have greater computing capacity available for misbehavior detection than vehicle OBUs, which are more resource restricted. Notifying legitimate vehicles of a possible attack even before they come into communication range of the misbehaving vehicle is another advantage of the suggested approach. It will work as follows: Every vehicle gets its credentials for communication during the registration process with the authority (CA). When a vehicle sends the Basic Safety Messages (BSMs), are received by all vehicles and RSUs within the sender vehicle's communication range. These BSMs along with the GPS data are used by the RSUs for identifying the misbehaving nodes through the hybrid detection module of the proposed framework. On detecting misbehavior, an alert is generated and is broadcasted to the vehicles and other RSUs in the communication range. When such alert is received by any vehicle, it updates the misbehaving node’s data into its local OBU to prevent future communication. The RSUs broadcast the alert to their respective vehicles in range and in such a way alert reaches the other vehicles through the network of RSUs.

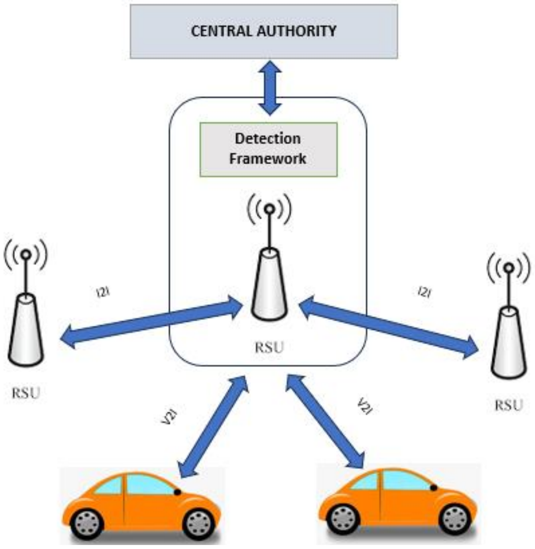

Fig. 3. Communication architecture.

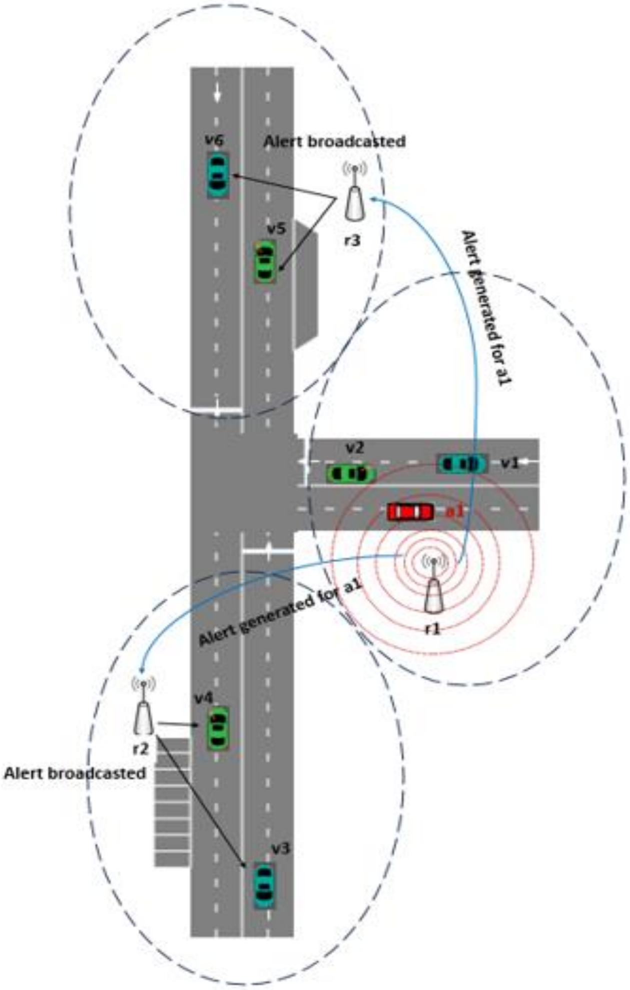

Fig. 4. VANET example scenario.

An example scenario is provided in Fig. 4 where v1, v2, v3, v4, v5, v6 are legitimate vehicles, a1 is a misbehaving vehicle, r1, r2, r3 are RSUs. Vehicle a1 is detected misbehaving by r1 which then broadcasts the alert to vehicles and RSUs in range. v1 and v2 being in range get this alert directly while v3, v4, v5 and v6 get this alert through the RSUs r2 and r3. In this way vehicles that are not even in range get the alert and are prevented from being attacked or misled. After detection of misbehavior, additional action may be taken by the CA depending on its own policy and procedures, which are not in the scope of this study.

B. Proposed Framework

The core contribution of this study is the framework for misbehaviour detection for the VANETs. The performance efficiency and the effectiveness of the suggested security framework are both significantly impacted by the entire features that are employed by the detection system. Detection accuracy, computational time and memory requirements have been identified as the primary factors for which the reduction in the total number of features is required by the system.

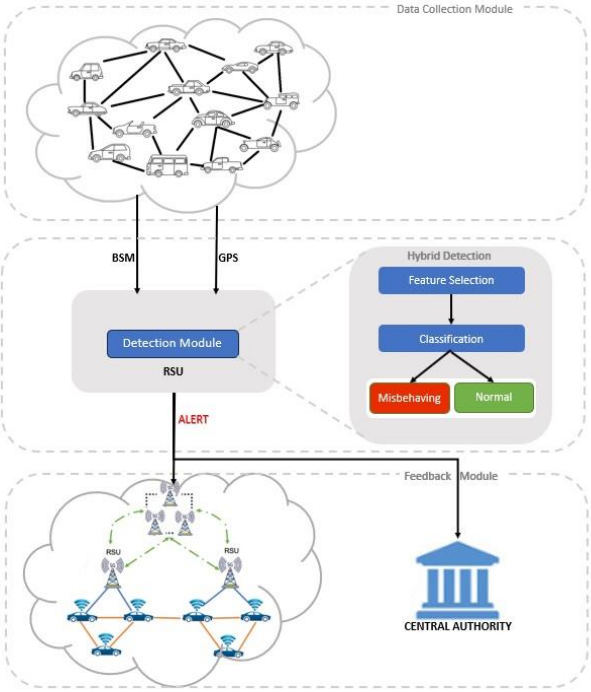

Fig. 5. Proposed Framework

The proposed framework (see Fig. 5) consists of three modules which include:

- Data collection module: This module collects the behavioural data and the contextual data from the network and sends it to the detection module.
- Hybrid Detection: This module primarily consists of a Genetic Algorithm model, which analyses the data, filters out the irrelevant characteristics, and reconstructs a low-dimensional feature dataset then uses supervised algorithms to categorize traffic, judge if it is being subjected to an attack, and decide whether to provide a warning in response to the findings.
- Feedback module: Using the machine's output status and alarm information, this module modifies its operations.

C. Processing Steps

There are two primary phases to implementing the suggested framework: dataset preparation and hybrid classification.

1) Dataset preparation: Every BSM has a unique message ID, the sender's ID, and a time stamp showing when it was sent in addition to the pertinent status information. A labelled VeReMi Extension dataset [19] was used for training and testing our proposed framework. It consists of message logs for each vehicle, which include BSM messages (labelled as type=3) received from other vehicles via DSRC, as well as GPS information (labelled as type=2) about the vehicle. There is one ground truth file and several unique log files for every simulation, which include the BSMs that each vehicle received. As a result, there are exactly as many log files as there are receivers. Every BSM is logged in several distinct log files as it is received by numerous vehicles. First to get rid of redundant information, the processing of the merged log files was carried out. After that, the combined log files and the ground truth file are merged, and a labelled dataset is produced for every simulation using this combined file.

2) Hybrid detection: After the required labelled dataset is ready, Artificial Neural Network (ANN) fitness function based Genetic Algorithm (GA) was used for feature reduction and detecting misbehavior.

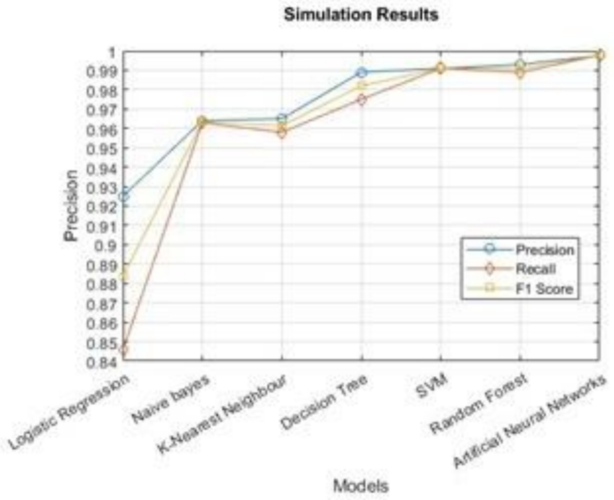

Fig. 6. Simulation Results for different fitness functions

a) Genetic Algorithm with ANN: Genetic Algorithm is used to solve a problem from a pool of potential solutions. GA is based on a fitness function, through which the generated candidates are iteratively developed, modified, and chosen for survival. Fitness functions are often manually constructed heuristics that rank candidate solutions according to how near they are to being accurate, with the candidate solutions that score higher being more likely to be picked for next generations [20]. Automating the creation of these fitness functions is still a difficulty, even though studies have found several successful applications of GA. In [21], authors have proposed an approach called NetSyn to automatically generate these fitness functions by representing their structure with a neural network. While they investigated this technique in the context of Machine Programming, they presented the technique to be applicable and generalizable to other domains also. Using that approach various classification algorithms have been explored that could be used as fitness function for GA. Among these, the following seven classifiers were selected: ANN, K-Nearest Neighbor (kNN), Random-Forest, Decision tree, Logistic Regression, Support Vector Machine (SVM) and Naïve Bayes, and compared the results (See Fig. 6). The results show that ANN yielded the best results among all. Algorithm 1 outlines the use of Genetic Algorithm with ANN Fitness function. The parameters used in GA are provided in Table I and the flowchart for the process is shown in Fig. 7.

Algorithm 1: Genetic Algorithm with ANN

```
BEGIN
Random initialization of population
For each generation (t) from 1 to max_generation:
    For each solution: evaluate fitness of each solution in the population
            Split the solution into 10 folds for cross-validation into ANN.
            Calculate and return the average accuracy as the ratio of correct predictions to the total number of predictions
    End
    Display progress information every 10 generations (optional).
    Sort the solutions based on their fitness.
    Select the two best solutions for reproduction.
    Apply Genetic Algorithm operators (crossover and mutation) to create new solutions.
    Update the population with the new solutions.
END
```

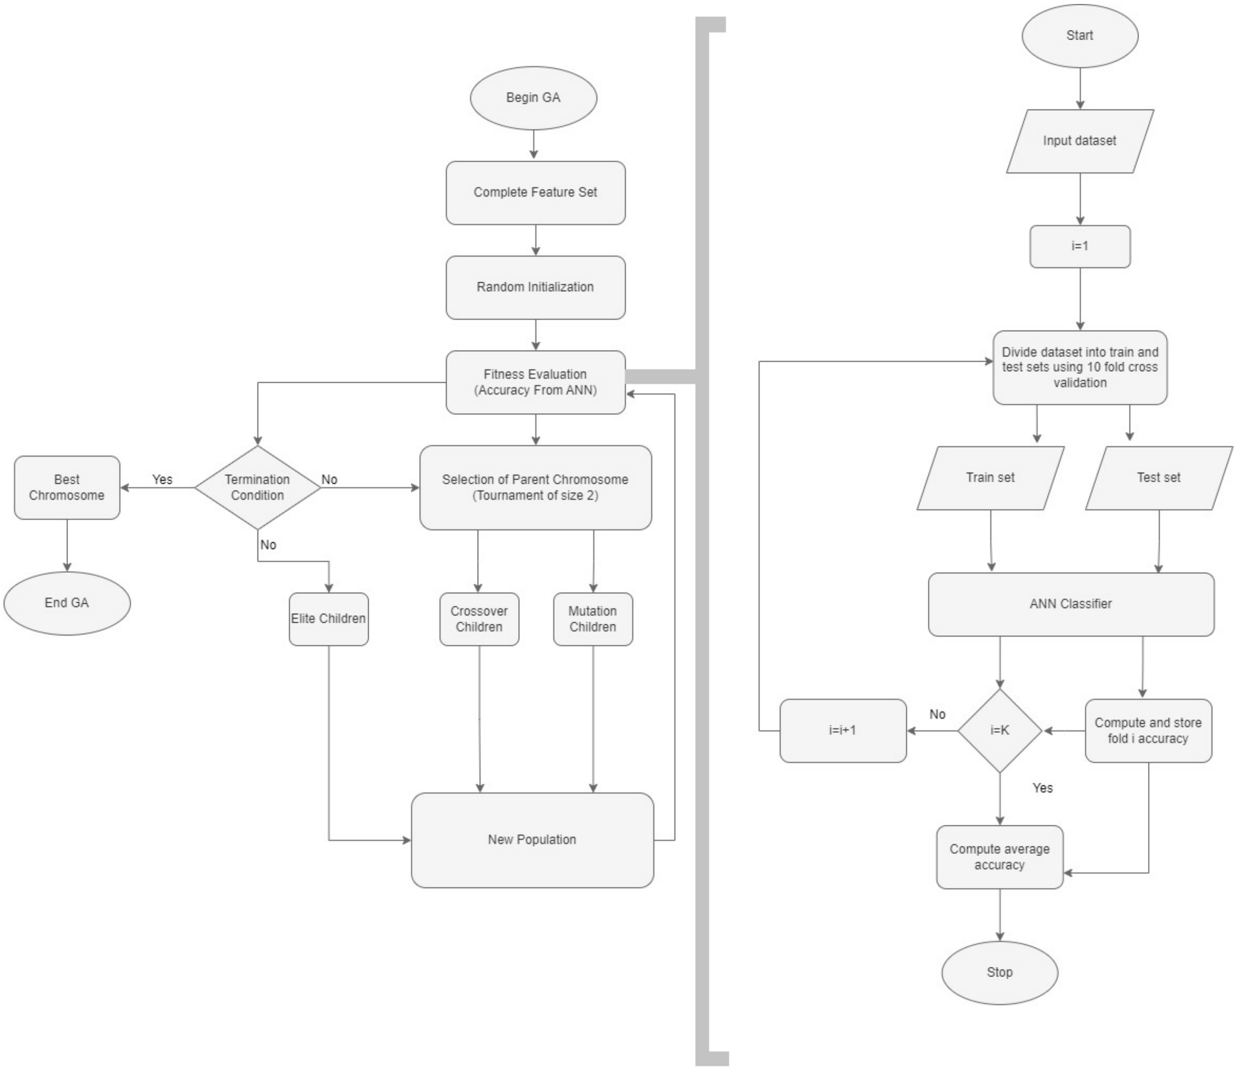

Fig. 7. Simulation Results Genetic Algorithm-based Feature Selection.

b) Cross-validation: To prevent the model from overfitting and effectively measure its accuracy, the entire dataset was split into k folds of train and test sets, with one split serving as the validation set and the remaining k-1 split as training set. Depending on the dataset, the value of k typically ranges from 5 to 10, and in this implementation, k = 10 has been used.

TABLE I. PARAMETERS USED IN GA

Parameter	Value
Genome length	33
Population size	300
Number of generations	500
Mutation	Uniform Mutation
Mutation Probability	0.1
Crossover	Arithmetic Crossover
Crossover Probability	0.8
Fitness Function	ANN-Based Classification Accuracy
Selection scheme	Tournament of size 2
Elite Count	2

IV. SIMULATION SETUP AND RESULTS

A publicly accessible VeReMi Extension dataset [19] has been utilized for training and testing the framework, to evaluate the suggested framework and guarantee fair comparisons. Using common metrics on this dataset, the suggested technique was evaluated and compared its results with those of previous approaches.

Information from both normal and misbehaving cars make the VeReMi Extension an imbalanced dataset [22]. The measures listed in Eq. (1) through Eq. (3) have been utilized for evaluating and comparing the performance of the proposed framework because accuracy by itself is insufficient as a metric for an imbalanced dataset. The misbehaving vehicle is indicated by a 1 in our dataset, whereas the genuine vehicle is shown by a 0.

$$Precision = \frac{True\ Positives}{True\ Positives + False\ Positives} \quad (1)$$

$$Recall \quad = \frac{True\ Positives}{True\ Positives + False\ Negatives} \quad (2)$$

$$F1\ Score \ = \ 2 * \frac{Precision * Recall}{Precision + Recall} \quad (3)$$

The implementation was carried out in two ways: binary classifications, to simply classify vehicles as normal or misbehaving and multiclass classification, to identify the specific misbehaviour being carried out.

A. Results

The results of the proposed framework's binary classification can be seen in Fig. 8. 99.99% of the cases may be identified accurately when utilizing the binary classification approach. When the ROC is analysed, the framework's good measure of separability is shown by an AUC (area under the curve) that is close to 1. With binary classification the framework has shown the precision, recall and F1 scores as 0.9999 for all three metrics.

The results of the multiclass classification of the proposed framework are displayed in Fig. 9. When employing the multiclass classification approach, the proposed framework has 99.76% detection accuracy. Since the AUC is close to 1, the framework is also performing quite well when it comes to multiclass categorization. With multiclass classification, the proposed framework has shown precision, recall and F1 scores as 0.9976, 0.9977, and 0.9977 respectively.

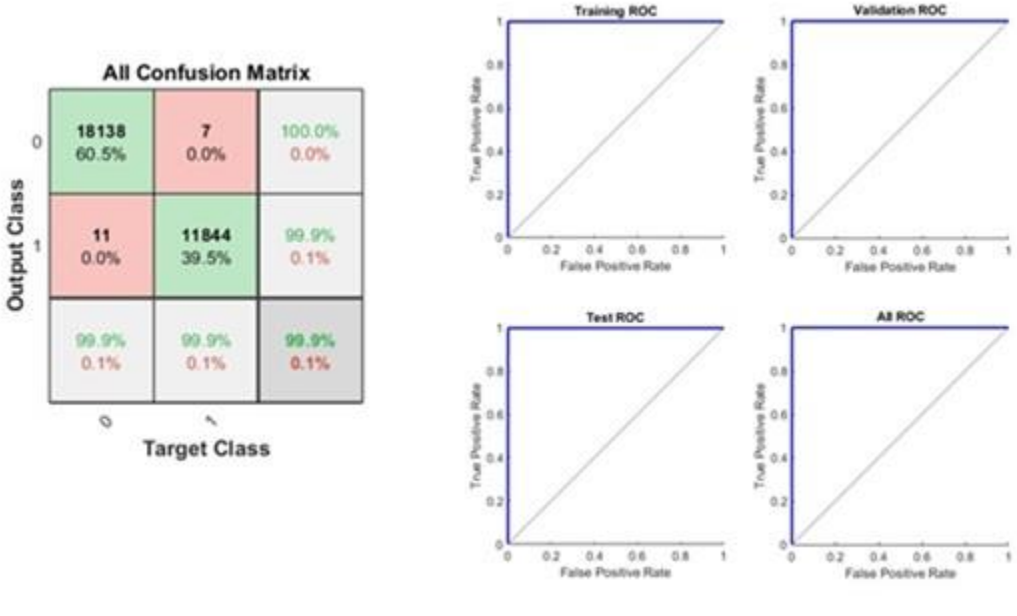

Fig. 8. Confusion matrix (left) and ROC (right) for binary classification.

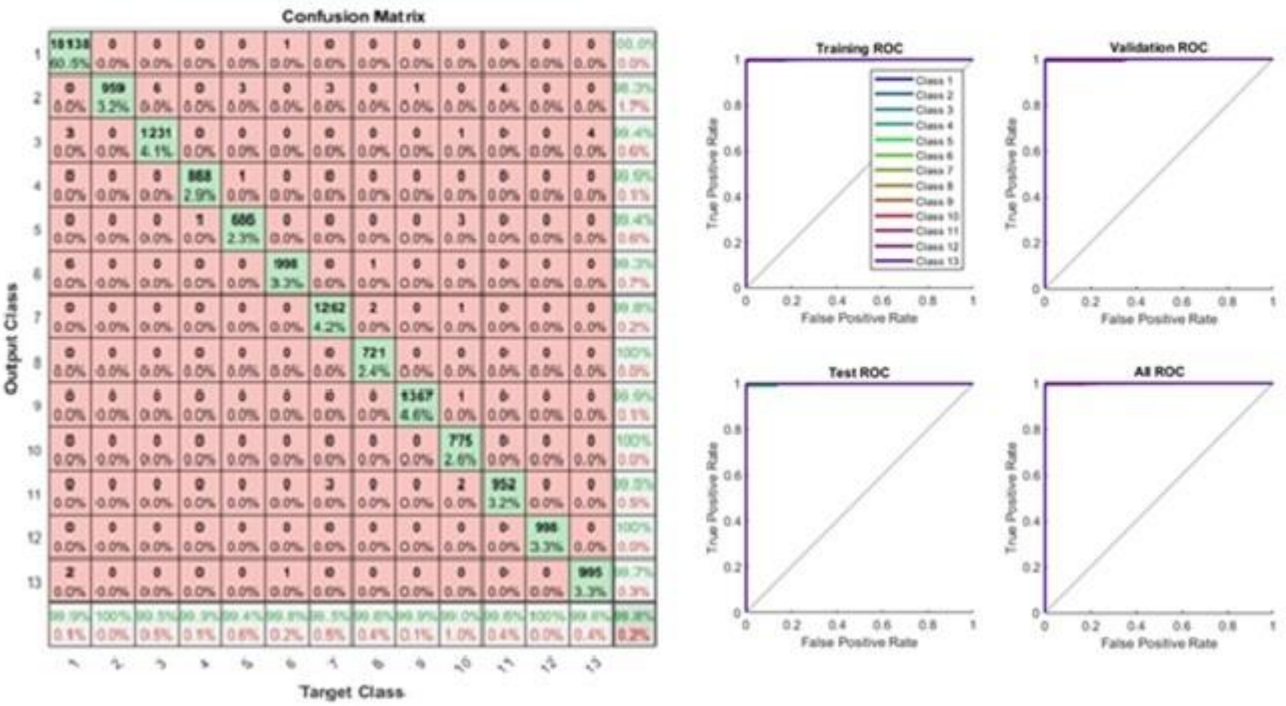

Fig. 9. Confusion matrix (left) and ROC (right) for multiclass classification.

B. Performance Evaluation with Varying Misbehaving Node Densities

Total five datasets were created with varying percentages of misbehaving nodes (10%, 20%, 30%, 40%, and 50%), and evaluated for the framework's performance under various misbehavior node densities. The simulation's outcomes are displayed in Fig. 10. The findings demonstrated that the framework demonstrated 100% accuracy with precision, recall, and F1 score all pointing to 1 when the proportion of misbehaving nodes was just 10% of the total number of nodes. The accuracy, recall, and F1 score values decreased as more and more misbehaving nodes were added to the dataset. Though the framework's performance was worse at 50% misbehaving nodes than in the 10% case, it still demonstrated 0.9967 recall, 0.9966 F1 score, and accuracy.

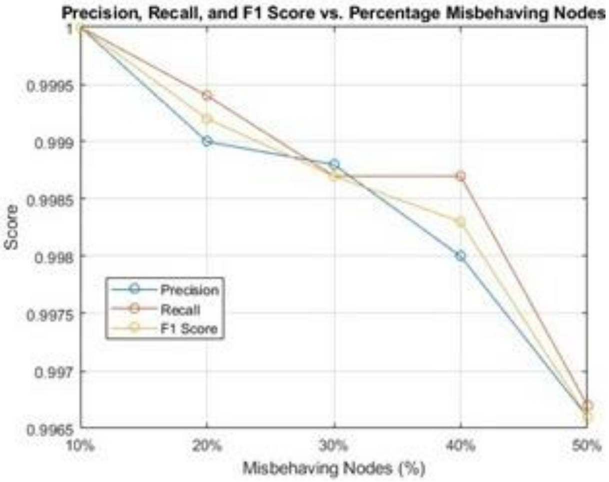

Fig. 10. Simulation Results for different node densities.

This demonstrates that even in the worst-case situations, where the fraction of misbehaving nodes is 50% of all nodes, our methodology is producing good outcomes.

C. Comparison with Existing Works

Table II presents a comparison between the existing works and the accuracy, recall, and F1 scores achieved using our proposed framework. The results make it evident that, in comparison to all other frameworks, Paper 4 [24] has extremely poor accuracy, recall, and F1 score values. While Paper 1 [23] had a high accuracy value of 0.9999 and performed comparable to the suggested model, it had a somewhat lower F1 Score and recall value. When it came to multiclass classification, the suggested model outperformed the other methods, with classifications showing 0.9976, 0.9977, and 0.9977 precision, recall, and F1 scores, respectively. When it came to binary classification, the framework displayed 0.9999 precision, recall, and F1 scores.

TABLE II. COMPARISON WITH EXISTING WORKS

Paper	Precision	Recall	F1 Score
Proposed Framework (with Binary Classification model)	0.9999	0.9999	0.9999
Proposed Framework (with Multiclass Classification model)	0.9976	0.9977	0.9977
Paper 1 [23]	0.9999	0.9554	0.977144
Paper 2 [11]	0.9886	0.8277	0.901023
Paper 3 [17]	0.988	0.99	0.988999
Paper 4 [24]	0.887	0.616	0.727069
Paper 5 [25]	0.978	0.932	0.954446

V. Discussion

The results of this study align closely with the theoretical framework presented in the introduction. The use of Genetic Algorithm (GA) with an Artificial Neural Network (ANN) fitness function for misbehavior detection in Vehicular Ad-hoc Networks (VANETs) is supported by the findings, which demonstrate high accuracy and robustness across different scenarios. This alignment validates the theoretical underpinnings of using a hybrid genetic algorithm approach for effective misbehavior detection in VANETs. The results of this study have several important implications for theory, practice, and future research. From a theoretical perspective, the success of the GA-ANN framework underscores the importance of context-awareness in misbehavior detection, as demonstrated by the use of GPS data and node behaviors as features in the classification process. Practically, this framework offers a robust and adaptive solution for VANET security, capable of detecting misbehaving nodes with high accuracy and efficiency. Compared to existing works in the field, the proposed GA-ANN framework demonstrates superior performance in terms of accuracy, precision, recall, and F1 scores. This highlights the effectiveness of the hybrid genetic algorithm approach in addressing the challenges of misbehavior detection in VANETs. The framework also outperforms existing methods in terms of adaptability to dynamic scenarios and robustness against evolving threats.

One of the key strengths of this study is the use of a comprehensive dataset and rigorous evaluation methodology, including 10-fold cross-validation, to assess the performance of the framework. However, one limitation is the reliance on simulated data, which may not fully capture the complexities of real-world VANET environments. Future research could involve testing the framework in real-world settings to validate its effectiveness further.

VI. Conclusion

This study presents a novel approach to detect misbehavior in VANETs using Genetic Algorithm with Artificial Neural Networks. Through the implementation of the misbehavior detection framework in the RSUs, which may broadly disseminate this information with other RSUs and vehicles, the proposed solution moves the computational burden from vehicles (OBUs). In contrast to existing methods, the proposed strategy uses ANN based fitness function in Genetic Algorithm. It was discovered after comparing several ML algorithms for fitness evaluation that ANN produces the best results.

The performance of the proposed framework was also compared with the existing solutions that have been published in the literature. The collected findings show that, in terms of precision, recall and F1 score, the suggested framework consistently outperforms the existing approaches across a variety of misbehavior types. Developing strong frameworks that can identify various misbehaviors using various GPS and BSM characteristics (such as heading, acceleration, and speed) is essential for safe VANET functioning.

Future research directions could focus on further enhancing the framework's performance by exploring different feature selection techniques or integrating other machine learning algorithms to improve classification accuracy. Additionally, extending the framework to address other types of misbehavior and incorporating real-time data processing capabilities could enhance its practical utility in real-world VANET environments.

SIC Holdings Co., Ltd, Hakata-ku, Fukuoka City, Fukuoka, Japan[2, 3, 4]

***Abstract*—A method for predictive trend analytics with social media information is proposed for marketing. Through keyword analysis, page view analysis, access analysis, heat map analysis, Google Analytics, real time analysis, company and competitor analysis, trend analysis with the social media data derived from X (former tweeter), Instagram, Facebook, YouTube, TikTok, market trend can be predicted. The proposed method is created in a local server and is extended to AWS cloud. The proposed system, also ensure negative / positive analysis from the acquired social media information. Through some experiments, it is found that by using AI to analyze social data by category, you can visualize the degree of attention for each keyword, model relationships between information, identify trending keywords, and where the keywords are in their lifecycle. It turns out that it's possible to categorize which ones exist and predict which ones will scale up in the next six months. In addition, corporate product development and marketing personnel can identify themes, materials, benefits, etc. that have signs of becoming popular based on insights based on predictive behavioral data obtained from the proposed method and system and utilize them in new business development and new product planning.**

Keywords*—X (former tweeter); Instagram; Facebook; YouTube; TikTok; market trend; AWS; Google analytics; keyword analysis; page view analysis; access analysis; heat map analysis

I. Introduction

Trend analysis is the process of predicting the future by analyzing changes in certain elements from the past to the present based on information obtained from SNS and websites. Marketing challenges include “difficult to understand cost-effectiveness," “rapid market changes," and “customer needs are diversifying, making it difficult to predict demand." Predict the market and overcome challenges with trend analysis: For example, if you want to know about changes in the market, you can use trend analysis to quickly catch trends in the field of products and services your company provides. Additionally, if it is used when formulating strategies such as production volume and advertising, it is possible to minimize costs.

In order to plan the right marketing measures, it is necessary to accurately understand and analyze all kinds of information. By conducting trend analysis, it is possible to grasp and analyze "information about competitors and market trends" necessary for marketing. In the process of trend analysis, it becomes easy to understand the differences between the products and services offered by your company and those of your competitors, as well as the differences in marketing. By collecting such information, it will be easier to determine the direction your company should take in future business development, and it will also be possible to predict market trends that will lead to the development of new products.

Furthermore, impressions and evaluations of products and services differ between company personnel and consumers. By conducting questionnaire surveys when analyzing trends, you can draw out the true feelings of consumers and formulate more effective marketing strategies. By creating personas using the collected data, you can plan measures that are optimized for users. The more detailed the persona settings are, such as age, gender, occupation, hobbies, and information sources, the better you will understand your customers, and the easier it will be to grasp the needs of actual users. By sharing this data within a company, it is possible to share an image between departments and eliminate misperceptions in marketing.

A method for predictive trend analytics with social media information is proposed for marketing. Through keyword analysis, page view analysis, access analysis, heat map analysis, Google Analytics, real time analysis, company and competitor analysis, trend analysis with the social media data derived from X (former tweeter), Instagram, Facebook, YouTube, TikTok, market trend can be predicted. The proposed method is created in a local server and is extended to AWS cloud. The proposed system, also ensure negative / positive analysis from the acquired social media information.

In the following section, some of the related research works are described in Section II, research background in Section III followed by the proposed method in Section IV. Then, some experiments are described in Section V, followed by a conclusion and future research works in Section VI and Section VII respectively.

II. Related Research Works

Database marketing has been successfully introduced in [1]. The book "Enterprise One to One: Tools for Competing in the Interactive Age" has also been published [2]. An attempt has been made to apply the concept of CLTV (Customer Lifetime Value) to FMCG (Fast-Moving Consumer Goods) [3]. Furthermore, several studies on CLTV have been introduced and reviewed, with each paper presenting different definitions of customer lifetime value, target industries, business models, and conditions for calculation [4].

Instances of COCA (Cost of Customer Acquisition) have been described, which refers to the cost of acquiring customers [5]. CLTV models and applications for marketing have been proposed and their applicability discussed [6]. Marketing study guides have been published and well-reviewed [7].

The book "Customer Profitability and Lifetime Value" has been published and extensively discussed [8]. Managing customers profitably has also been investigated and discussed [9]. Additionally, the analysis and discussion of "Performance management, which includes integrating strategy execution, methodologies, risk, and analytics," has taken place [10].

The paper "RFM (Recent Frequency Monetary) and CLTV: Using iso-value curves for customer base analysis" has been published, proposing and validating a method for marketing research [11]. Similarly, the paper "Autonomous CRM control via CLTV approximation with deep reinforcement learning in discrete and continuous action space" has been published, attempting to use CLTV approximation for CRM control [12].

On the other hand, CLTV has been well defined and discussed [13]. The paper "EDA of predictive modeling with “R” (a software tool for statistics) for risk management using machine learning" has been published, proposing and validating the use of EDA for predictive modeling [14]. Meanwhile, it is widely acknowledged that EDA is an important and useful technique in data science for analyzing and understanding data better. EDA involves exploring and visualizing the data to identify patterns, relationships, and anomalies.

EDA helps identify missing values, outliers, and other inconsistencies in the data, which can then be addressed before building predictive models. By visualizing the data, EDA also facilitates communicating insights to stakeholders and guiding further analysis. Furthermore, EDA is increasingly recognized as a critical step in any data analysis project as it enables a better understanding of the data, identification of potential issues, and provides insights for further analysis and decision-making. The concept of EDA has also been proposed and discussed [15]. Data analysis and regression have been well proposed for EDA analysis [16].

The paper "Suitability of random forest analysis for epidemiological research: Exploring sociodemographic and lifestyle-related risk factors of overweight in a cross-sectional design" has been published, studying and reporting on the suitability of random forest analysis for epidemiological research [17]. Additionally, EDA has been well defined, described, and investigated for its usefulness [18].

The paper "Customer Profiling Method with Big Data based on BDT and Clustering for Sales Prediction" has been published, proposing and validating a method for sales prediction using big data [19]. Meanwhile, the paper "Modified Prophet+Optuna Prediction Method for Sales Estimations" has been published, also proposing and validating a prediction method for sales using actual sales data [20].

III. Research Background

Google Trends is a free tool provided by Google. According to the Ministry of Information and Communications White Paper 2020 Edition, Google will have an 85.6% share of search engines in the world in 2022. By using Google Trends, it can be checked the trend of popular words searched on Google, which has a high share rate in the world, and the rapidly increasing words. For example, it is not only possible to predict demand based on rapidly increasing keywords, but also to understand whether the market is expanding or contracting by checking the increase or decrease in the number of searches for a specified word.

This free tool provided by Yahoo! JAPAN is unique in that it allows you to check X trends in real time. Yahoo! Real-time Search has a feature that allows you to analyze emotions by displaying the ``emotion percentage" in a pie chart, so it can be seen whether the posted content is negative or positive. If opinions about a company's advertising marketing tend toward negative posts, it can be taken improvement actions based on those comments. If it is searched for your company's name or the name of the product or service it offers using X, it can be performed a so-called "ego search" and check the true intentions of a company in real time without any presumptions.

When using SNS for trend analysis, it is important to take advantage of the characteristics of each SNS. In the case of Instagram, a feature is that it analyzes the situations in which trending products and services are used. In the case of X, a feature is that it analyzes what kind of impressions is being expressed about trending products and services. Additionally, in the case of YouTube, a feature is that it analyzes what kind of marketing measures are being taken by other companies.

The usage rate of SNS used by users differs depending on the age group. Only YouTube has a usage rate that accounts for more than half of all age groups, while the usage rate of other SNSs peaks among people in their teens or 20s and then declines. In particular, regarding TikTok, the usage rate among teenagers is 62.4%, while the usage rate among people in their 40s and above has dropped by around 50 points. The number of SNS users is 330 million on X, 1 billion on Instagram, 1 billion on TikTok, 2.934 billion on Facebook, 573 million on Weibo, 193 million on LINE, Pinterest has 444 million people.

The information that can be obtained with PyTrends[1] is things that are gaining attention, interest by subarea, related information, related keywords, and rapidly increasing rankings by year. It provides search suggestions, obtains category content, and investigates up to five keywords at a time for the above items.

TrendScope is a tool that analyzes all of X's past several years of data and articles published in the media, and extracts data that can be used for management decisions, product development, and marketing. It not only captures the current state of the market from the tweets of consumers, but also analyzes past data, making it possible to grasp signs of the future. We can identify which keywords are currently trending, categorize where they are in their lifecycle, and predict which ones will scale up in the next six months. A company's product development and marketing staff can identify themes, materials, benefits, etc. that have signs of becoming a trend, using insights based on predictive behavior data obtained from TrendScope, and utilize this information in new business development and new product planning.

Trends in the world, for example, McDonald's, after the first trend ended, it spread explosively with the second trend. We use AI to catch up on such trends and develop services and

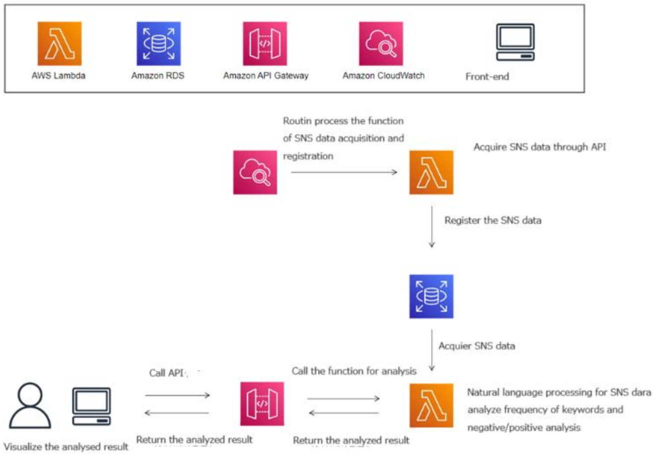
[1] PyTrend：https://norari-kurari-way.com/python-trend/

products that are on-trend. Analyzing the keywords that are rapidly increasing on SNS, knowing the trends at that time, and utilizing them for product development. In addition to product development, by analyzing consumer voices posted on SNS, etc., we can improve existing services. We would like to use this knowledge to improve and create new services that people want. It also collects people's tweets on social media, analyzes the tweets using AI to find trends, and visualizes the analysis results on the screen.

Monitor X posts using Yahoo! Real-time search. It can be checked the number of tweets that include a specific keyword and the actual content of the tweets, and it can be also sorted tweets by newest arrival or topic. In the "emotion ratio" section, posts are automatically judged, and the ratio of positive/negative posts can be displayed. Since we are unable to confirm specific tweets that have been judged positive/negative, we can only confirm these figures as reference numbers. There are tools that can help it finds keywords related to a company that are being talked about and prevent the risk of becoming a hot topic.

IV. Proposed Method

The proposed method allows acquisition of tweet information as an example of SNS information for trend prediction with tweet API in the environment of AWS. The system configuration is shown in Fig. 1.



AWS Lambda
Amazon RDS
Amazon API Gateway
Amazon CloudWatch
Front-end
Routin process the function of SNS data acquisition and registration
Acquire SNS data through API
Register the SNS data
Acquier SNS data
Call API
Call the function for analysis
Natural language processing for SNS dara analyze frequency of keywords and negative/positive analysis
Visualize the analysed result
Return the analyzed result
Return the analyzed result

Fig. 1. System configuration of the proposed method for tweet information acquisition relating to trend analysis and prediction based on AWS environment.

There are four major functionalities, AWS Lambda, Amazon RDS, Amazon API gateway, and Amazon CloudWatch together with front end under the user interfaces. As a routine process, the function of SNS data acquisition and registration is always working. With the Lambda, SNS data are acquired through API. Then the acquired SNS data are registered to the Amazon RDS. When users call the API and the function for SNS data analysis, natural language processing is activated. The frequency of keywords is analyzed. Also, after the morphological analysis (part of speech analysis and separation of words) as a part of natural language processing, the acquired SNS data of texts are analyzed with negative or positive of emotional impressions through Lambda. Then the analyzed results are transferred to the users with the front end of visualization terminals.

The database of entities is shown in Table I and Entity Relations are shown in Fig. 2.

TABLE I. Database of Entities

No	Name	Table	Usage
1	User	Customer	Customer Information Control
2	tweet_data	Acquired tweet data	Acquired tweet data control
3	result_data	Tweet analysis result	Tweet analyzed result control
4	category	Category	Category control
5	industry	Industry society	Industry information control

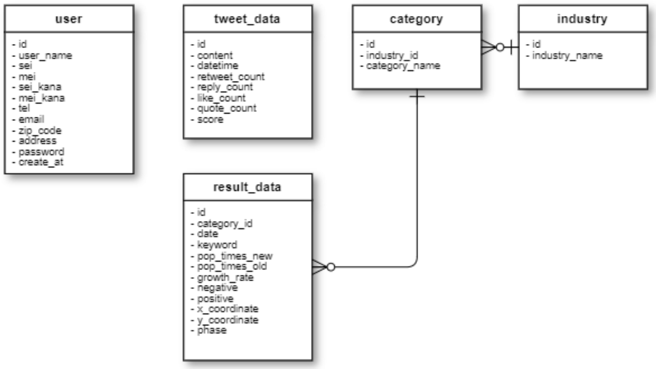


Fig. 2. Entity relations.

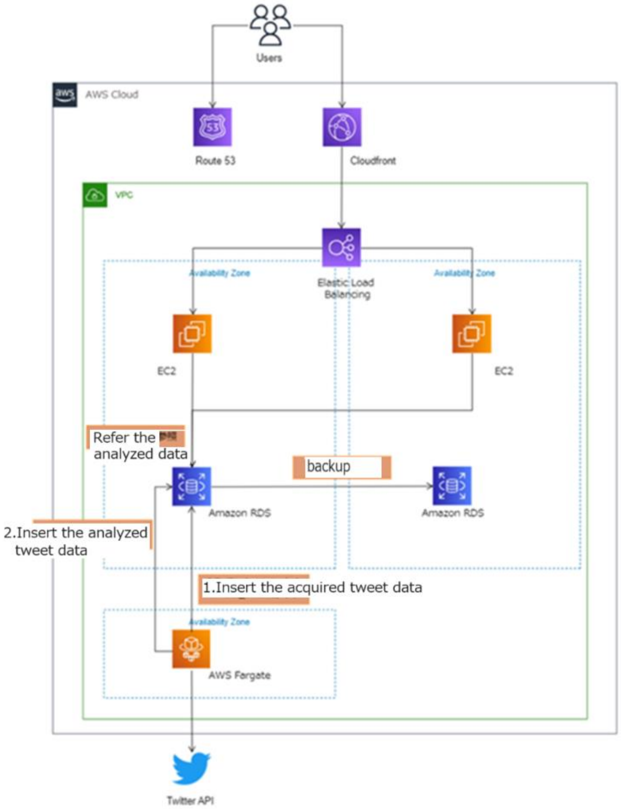

Fig. 3. Detailed configuration of the proposed trend analysis system.

There are five tables in the Amazon RDS, User, Tweet data, Category, Industrial society (Companies in the same industrial society, etc.), and Analyzed result data. The acquired tweet data are categorized based on users, companies. Analyzed results are highly correlated with the categories together with industrial society.

The detailed configuration is shown in Fig. 3. In the figure, backup control scheme and insertion of the acquired SNS data of tweet information as well as referred analyzed results through EC2 are shown. As for the front end, display design of user authentication is shown in Fig. 4. Users have to input their ID and password for authentication and may enter the proposed trend analysis system. After the user authentication, tweet data is collected in accordance with the keywords. Then trend analysis results are appeared together with negative / positive analysis against tweet information of text data. In this stage, “MeaningCloud” of sentiment analysis tool is used as shown in Fig. 5. Thus, the users may realize the impression of tweet information whether or not good or bad. The trend of the users’ impression, then shown in the detailed trend analysis result.

V. Experiment

The aforementioned functionalities of the proposed trend analysis system are performed and confirmed. After the user authentication, the main menu appears on the screen as shown in Fig. 6. Pul-down menu is then displayed, “Industry name”, “Category”, “Area”, and “Period” appears. In Fig. 6, “Hair salon”, “Shampoo”, “Japan”, and “January 2023” are selected for each. After all, Analysis of radio button is clicked. Then trend analysis begins.

Fig. 7 shows an example of the detailed trend analysis result with the aforementioned keywords which are shown in Fig. 6.

15	バラ	Roses	80	+40%	50 20

Fig. 7. Example of the detailed trend analysis result with the aforementioned keywords.

In January 2023, the top three of the keywords collected from the tweet information with the keyword of “Shampoo” in the hair salon companies in Japan are (1) Botanical, (2) Mad and (3) Beauty. The number of keywords appeared in tweet information for the corresponding top three keywords are 5394, 5311, and 3455. Furthermore, the grow rate of the corresponding keywords is 40.4 %, 20.3 %, and 11.0 %, respectively. Moreover, the sentiment analysis results show almost same ratio of negative and positive impressions of the keywords, 50 % of negative, 30 % of neutral, and 20 % of positive.

Another example is shown in Fig. 8. In January 2023, the top three of the keywords collected from the tweet information with the keyword of “Hair salon” in the hair salon companies in Japan are (1) Hair, (2) I and (3) What. In this case, the extracted keywords are the results from the morphological analysis so that the words are a part of speech. Also, API keys are increased to collect multiple keywords. API option to exclude retweets at the collection stage is added. We delete “Author_id” and delete retweets from existing acquired data. In the meantime, negative / positive analysis is also performed at the time of acquisition for matching with method Positive and Negative dictionary. The number of keywords appeared in tweet information for the corresponding top three keywords are 626, 562, and 411. Furthermore, the grow rate of the corresponding keywords is 22 %, 26 %, and 45 %, respectively. Moreover, the sentiment analysis results show almost same ratio of negative and positive impressions of the keywords, 20 % of negative, 55 % of neutral, and 25 % of positive.

Fig. 9. Stored tweet information of data in Amazone S3.

There is the extended option in the Amazone S3. In the option, detailed tweet information of “pop_times_new”, “pop_times_old”, “growth_rate”, “positive_pct”, and “negative_pct” can be displayed as shown in Fig. 10.

At this time, these tweet information collection, sentiment analysis, and trend analysis run the tweet analysis code using Docker. Similarly, the front end is also implemented on Docker. It was also confirmed that the analysis results were inserted into the Docker DB. When we did this locally, the import took too long, so we had to do it manually, but we changed it to run the tweet analysis method on Docker. At this time, tweets are still being retrieved from S3. Therefore, we made it possible to retrieve it from the DB. Using “FastAPI”, we created an API with Docker to retrieve analysis results from the database. It also allows narrowing down the search by keyword or period.

Fig. 10. Example of the extended option display for the acquired tweet information and the negative / positive impressions of sentiment analysis results.

Negative / Positive analysis was also performed when tweets were regularly acquired, and the negative/positive scores were added as an item to the tweet data table as shown in Fig. 11. This is expected to reduce the load during analysis. In the table, tweet ID, Content, author ID, date and time, retweet, and reply, like, quote, positive / negative score are included.

VI. Conclusion

A method for predictive trend analytics with social media information is proposed for marketing. Through keyword analysis, page view analysis, access analysis, heat map analysis, Google Analytics, real time analysis, company and competitor analysis, trend analysis with the social media data derived from X, Instagram, Facebook, YouTube, TikTok, market trend can be predicted. The proposed method is created in a local server and is extended to AWS cloud. The proposed system, also ensure negative / positive analysis from the acquired social media information.

Through some experiments, it is found that by using AI to analyze social data by category, you can visualize the degree of attention for each keyword, model relationships between information, identify trending keywords, and where the keywords are in their lifecycle. It turns out that it's possible to categorize which ones exist and predict which ones will scale up in the next six months. In addition, corporate product development and marketing personnel can identify themes, materials, benefits, etc. that have signs of becoming popular based on insights based on predictive behavioral data obtained from the proposed method and system and utilize them in new business development and new product planning.

VII. Future Research Works

Further investigations are required for not only tweet information derived trend analysis but also Instagram, Facebook, YouTube, TikTok, and so on for market trend has to be predicted in the near future.

Acknowledgment

The authors would like to thank to Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda for their valuable discussions.

AUTHOR'S PROFILE

Kohei Arai, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January, 1979 to March, 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science on April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA for 1998 to 2020 and is Adjunct Professor of Nishi-Kyushu University as well as Kurume Institute of Technology pplied AI Laboratory) up to now. He also is Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008 then he is now award committee member of ICSU/COSPAR. He wrote 77 books and published 710 journal papers as well as 550 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. http://teagis.ip.is.saga-u.ac.jp/index.html

Study on the Implementation of Multimodal Continuous Authentication in Smartphones: A Systematic Review

Rahmad Syalevi[1], Aji Prasetyo[2], Rizal Fathoni Aji[3]
Faculty of Computer Science, University of Indonesia, Jakarta, Indonesia[1, 3]
Database Center, Indonesian Agency for Meteorology, Climatology, and Geophysics, Jakarta, Indonesia[2]

***Abstract*—Profound societal shifts result from the inception of the 4.0 age of the Industrial Revolution and rapid technological advancements. The widespread adoption of e-services has resulted in substantial reliance on smartphones to access diverse offerings. Even so, account breaches and data leaks are risks that users take when they rely so heavily on their smartphones. Authentication is an essential method of safeguarding personal information. The purpose of this study is to undertake a thorough review of the literature on the deployment and trends of multimodal biometric authentication on smartphones. The studies will look at several biometric modalities, such as behavioral and physiological characteristics, and the algorithms for pattern recognition used in continuous authentication systems. The results show various biometric authenticators and emphasize the importance of behavioral features in smartphone authentication. In addition, the research underlines the significance of machine learning algorithms in pattern identification for rapid and accurate analysis. This study helps to understand the present authentication technique landscape and gives ideas for future advances in safe and user-friendly smartphone authentication systems.**

***Keywords*—Authentication; continuous multimodal; biometric authenticator; smartphone**

I. Introduction

The Fourth Industrial Revolution gave birth to significant social disruption, characterized by rapid and highly advanced technological advancements with a particular emphasis on artificial intelligence, big data, and integration systems [1]. This trend encourages every element of society to use electronic service systems in every activity, ranging from the world of business, banking [2], transportation [3], and social organization [4].

In addition, many people use smartphones to access various electronic services via the internet, with 6.4 billion users or 79 percent of the world's total users. The utilization rate of intelligent mobile devices is significantly higher than other devices, such as portable computers and tablets [5].

Internet connection on intelligent mobile devices carries the risk of security vulnerabilities such as account theft and data leakage of its users [6]. Authentication is a meaningful way to keep personal information, such as personal data and more, from falling into the wrong hands [7]. Android devices have used authentication schemes, including pin codes or passwords, patterns, fingerprints, and biometrics [8], where patterns, pins, and alphanumeric passwords are still the preferred way to log into Android devices [9], computers, and web applications such as email, cloud storage, and online shopping services [10], [11].

A knowledge-based authentication, physiological biometrics authentication, behavioral biometrics authentication, and multi-factor authentication are the essential components that comprise the taxonomy of user authentication systems on mobile devices [12]. Regarding security, knowledge-based verification uses information that only people and systems know. The secret can be text, like PINs, codes of letters and numbers, or a picture, like a pattern [12].

Traditional or knowledge-based single-factor authentication has become a significant concern for security practitioners and researchers. While still a viable option due to its simplicity, using PINs, passwords, and patterns as authentication inputs comes with several vulnerabilities, such as surfing and smudge attacks and susceptibility to intercept [13]. Also, password vulnerability causes most users to use passwords that are easy to guess and do not change regularly [14]. The Cybersecurity and Infrastructure Security Agency (CISA) has also added single-factor authentication, such as password matching, to gain access to a system as a bad practice [15].

Other approaches initially anticipated that multi-factor authentication would enhance security [16] and ease ongoing protection for computing devices [17] and other critical services [18] from unauthorized access by using more than two types of credentials [19], such as biometrics and secret knowledge [12]. However, the enhanced security force is still limited. This limitation is supported by other studies that have understood the failure of multi-factor authentication on mobile devices [20]. One flaw in this scheme is that an attacker attempts to intervene in a communication between two interacting parties and modify the message or information transmitted so that the attacker can gain access to confidential data or perform unlawful acts. Furthermore, synchronization issues, hardware alterations, or faults in the implementation of authentication protocols might be used by attackers to gain sensitive information or carry out illicit acts.

Continuous user authentication approaches on smartphones through sensors, multimodal behavioral biometrics, and machine learning models have been introduced in recent research [21], [22], [23] to resolve the previously mentioned issue, improve accuracy, and reduce interference in authentication mechanisms. This method gives a higher level of protection while accessing electronic services via mobile devices, such as smartphones. Previous research in [24] has also conducted systematic reviews of continuous multimodal biometrics but has yet to focus on smartphone implementation. Therefore, this study investigates the possibility of implementing continuous multimodal authentication in mobile devices such as smartphones.

The structure of this paper is as follows. Section II presents the related works. Section III clarifies the concept of multimodal biometrics. Section IV describes the methods used in the study. Section V provide the study's findings and discuss its implications. In Section VI, we present the conclusion and outline future work.

II. Related Work

We discovered limited papers focusing on multimodal continuous authentication in smartphones. Researchers have examined authentication in various ways. For instance, [12] conducted surveys of existing authentication methods on mobile devices, while [13] suggested a behavioral biometric authentication scheme as secure and convenient. Moreover, [17] concluded that biometric authentication alone was insufficient and proposed multi-factor authentication mechanisms for more robust security. The study in [20] explored security vulnerabilities in multi-factor authentication schemes on mobile devices, while [21] identified continuous authentication with behavioral biometrics in smartphones as insightful and challenging for adoption. Furthermore, [23] found that continuous multimodal biometric authentication offers high accuracy and improved security, and [24] suggested implementing and evaluating such systems to demonstrate their feasibility. Based on these studies, we aim to investigate the implementation of multimodal continuous authentication in mobile devices, such as smartphones.

III. Multimodal Biometric

Biometric refers to recognizing patterns that establish a person's identity by comparing biological or behavioral features of biometric attributes. Biometric traits are a highly convenient means of verifying an individual's identity, as they offer high security (difficult to replicate) and cannot be stolen, forgotten, or misplaced [25].

Fingerprints, palm prints, hand geometry, faces, eyes, ears, electrocardiograms, and electroencephalograms are all physiological biometrics used in modern smartphones. Tapping behavior, hand motions, noises, gait, and daily activities are all examples of biometric behavior [12].

A biometric system is, in essence, a pattern recognition system that collects biometric data from a person, extracts a set of features from that data, and then compares the extracted features to a background of templates saved in a database. This process is known as "biometric matching." To put it another way, a pattern recognition system is what a biometric system is. Its performance is determined by the context in which it is used; for example, depending on the context, it may function in either a verification or identification mode [25].

Unimodal and multimodal represent two distinct categories within biometric systems, with their primary distinction lying in the number of modalities employed for authentication purposes. Unimodal biometric systems, exemplified by fingerprint and facial recognition technologies, are easier to create since they only require one identity. However, they are vulnerable to problems like spoofing and poor identification. On the other hand, multimodal systems, such as those combining facial and voice recognition or iris and fingerprint recognition, provide enhanced protection, durability, and adaptability to external influences by employing multiple characteristics. Their intricacy, however, resides in figuring out what, when, and how to combine data for authentication across several modalities [24].

IV. Methodology

The research strategy used for this project was called a Systematic Literature Review (SLR). The SLR technique is a tried-and-true research approach when gathering and analyzing data on a specific issue. We have used the PRISMA guidelines provided by Matthew J. [26]. This SLR consists of four main steps: primary study planning and search, study collection, data extraction, and data synthesis. Section IV(A) identifies research objectives and questions as the first step. In Section IV(B) and IV(C), search strategy steps involve study selection criteria, study selection procedures, keyword formulation for research, and search queries. In Section IV(D), the final step requires quality assessment.

A. Research Question and Objectives

The primary purpose of this SLR is to explore the implementation of continuous multimodal authentication in Smartphones. We create research questions to focus on the objectives of this research.

RQ1: What biometrics is used for authentication on smartphones?

RQ2: What technique is used for pattern recognition in continuous authentication on smartphones?

Based on this research question, the focus of this research objective is to review trends that have occurred in recent years, particularly the use of continuous multimodal authentication on smartphones, and explore biometric combinations used for authentication on smartphones.

B. Search Strategy

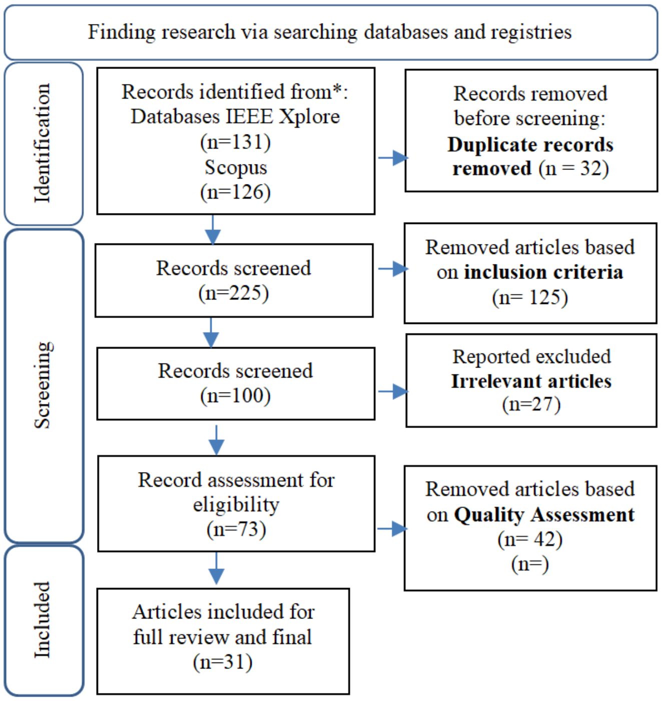
In this study, we searched using the electronic databases IEEE Xplore and Scopus. We prepared several lists of keywords to search for relevant literature on multimodal biometric authentication in smartphones from selected electronic databases. The search query utilized was:

“continuous” AND (*biometric* OR *multi*) AND (“authentication” OR “verification” OR “validation”) AND “smartphone” OR “mobile phone.”

Queries applied to article titles, abstracts, and keywords to get relevant articles from electronic databases.

C. Selection Criteria

We analyze the query results that have been obtained by removing duplicate articles. Filtering is also done based on the article’s title, abstract, and keywords. In addition, we also use inclusion and exclusion criteria. Fig. 1 shows the PRISMA diagram for this meta-analysis.



Finding research via searching databases and registries
Identification
Records identified from*: Databases IEEE Xplore (n=131) Scopus (n=126)
Records removed before screening: Duplicate records removed (n = 32)
Screening
Records screened (n=225)
Removed articles based on inclusion criteria (n= 125)
Records screened (n=100)
Reported excluded Irrelevant articles (n=27)
Record assessment for eligibility (n=73)
Removed articles based on Quality Assessment (n= 42) (n=)
Included
Articles included for full review and final (n=31)

Fig. 1. The PRISMA diagram for this meta-analysis.

We use the following inclusion criteria. The paper or article should talk about authentication in smartphones. In addition, papers or articles must be in English and published from 2018 – 2022 in journals or conference proceedings.

We used several article selection exclusion criteria in this study. Papers or articles discuss the continuous multimodal biometric authentication but not in smartphones. In addition, papers or articles in the title, abstract, or keyword section do not mention authentication; articles with survey methods or systematic reviews are not attached to the results of this study.

D. Quality Assessment

Quality assessment is used to assess the quality of the selected article. The quality assessment also evaluates whether the selected article is fully accessible and can answer our review. To determine consistency, we formulated some quality assessment questions.

QA1: Does the article mention the use of continuous multimodal biometric authentication, and is it clearly stated?

QA2: Does the article provide an answer to the formulated RQ?

QA3: Are the aims of the research clearly stated without ambiguity in the paper?

Yes or no can answer each question with weights of 1 and 0, respectively. The results are evaluated after an assessment of the quality of the entire article has been carried out. The quality assessment process is intended for all research articles according to quality assessment questions. Therefore, this review includes all 31 selected articles.

V. Result and Analysis

The study's conclusion will involve presenting research papers that investigate continuous authentication using multimodal methods. Additionally, the second step consists of conducting a mapping exercise to explore the application of biometrics based on specific biometric properties.

A. Significant Journal

In this literature review, 17 journal articles and 14 conference proceedings discuss continuous multimodal authentication. Here is a brief overview of the distribution of publications journals over the past five years. The result is shown in Table I.

Based on Table I, an in-depth analysis of the provided data reveals a diverse collection of journals across different quartiles. Within the esteemed Q1 quartile, we find a constellation of scholarly publications, including Computers & Security, Journal of Network and Computer Applications, IEEE Transactions on Industrial Informatics, IEEE Access, IEEE Internet of Things Journal, Human-centric Computing and Information Sciences, and IEEE Signal Processing Letters. Remarkably, these journals exhibit varying publication frequencies, ranging from 1 to 2, which discuss continuous authentication.

Transitioning to the intellectually stimulating Q2 quartile, we encounter an array of influential journals that contribute significantly to their respective fields. Noteworthy publications such as Electronics Microprocessors and Microsystems, IEEE Transactions on Information Forensics and Security, International Journal of Distributed Sensor Networks, and Sensors grace this quartile, each showcasing their research prowess with a single publication.

TABLE I. Distribution of Publications

Quartile	Journal Name	Quantity
Q3	International Journal of Advanced Computer Science and Applications	1
Q1	Computers & Security	1
Q1	Journal of Network and Computer Applications	2
Q1	IEEE Transactions on Industrial Informatics	1
Q1	IEEE Internet of Things Journal	1
Q2	Electronics	1
Q2	Microprocessors and Microsystems	1
Q1	IEEE Access	2
Q1	Human-centric Computing and Information Sciences	1
Q2	IEEE Transactions on Information Forensics and Security	1
Q2	International Journal of Distributed Sensor Networks	1
Q3	Wireless Communications and Mobile Computing	1
Q4	Indian Journal of Computer Science and Engineering	1
Q2	Sensors	1
Q1	IEEE Signal Processing Letters	1

Intriguingly, the scholarly landscape unveils the distinguished International Journal of Advanced Computer Science and Applications as the sole journal within the intellectually captivating Q3 quartile, signifying its profound impact with a singular publication.

B. Biometric Authenticators

A biometric is a pattern recognition system that establishes a person's identification by comparing biological or behavioral traits of biometric characteristics [26].

Table II presents a captivating exploration of the landscape surrounding biometric authentication within continuous multimodal biometric authentication systems on smartphones, offering a comprehensive overview of the diverse range of biometric authentication methods utilized in intelligent mobile authentication systems that seamlessly integrate multiple biometric modalities sustainably. From this table, we can identify and analyze various biometric authenticators employed in these systems, unveiling a rich tapestry of authentication techniques.

In addition, Fig. 2 illustrates the prevalence of different biometric modalities in authentication systems, revealing that 84% of behavioral characteristics are widely used for smartphone authentication, 13% choose to use physiological factors, and 3% combine behavioral and physiological characteristics. Notably, human gait, routine activities, and touch/swipe functions are emerging as highly preferred options for enhancing the security of continuous authentication processes.

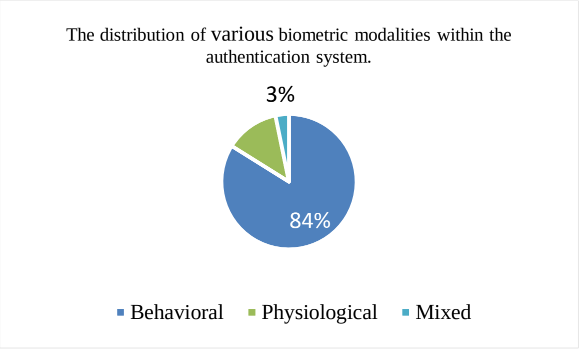

Fig. 2. The proportion of diverse biometric modalities utilized in the authentication system.

An innovative smartphone unlock scheme to improve user authentication through swipe behavior becomes a unique approach where the user selects a background image and performs a swipe action at a specified location on the smartphone screen. This combination ensures secure and reliable authentication, providing an additional layer of protection for smartphone users [27]. Other combinations, such as swipe and tap, result in increased security through continuous user authentication by paying attention to factors such as vibrations from walking, the effects of different positions, and trembling hands in cold temperatures [31] and the number of tap gestures implemented without any combination [49], [50], [57].

The continuous implementation of authentication and identification security is also demonstrated using behavioral characteristics in everyday life. Activities of daily living, such as walking, typing, and clapping, can be used for authentication and biometric identification. This demonstrates the feasibility of using natural activities for continuous biometrics with the help of smartphone motion sensors and inertial measurement datasets [53], [55]. Another approach through an innovative scheme also offers a dynamic and personalized user validation process by analyzing six everyday activities: walking, running, standing, sitting, walking up, and walking down. The variety of positions for smartphone placement on the user's body affects the user's recognition of each specific activity. This can optimize sensor placement and improve the overall performance of recognition systems [40].

The development of human gait recognition for smartphone access shows the advantages of biometric authentication methods to enhance security and prevent illegal user access [28]. The system's hidden nature, which does not require user interaction, further confirms its advantages as a convenient and user-friendly layer of security [30]. By utilizing smartphones' built-in inertial sensors, data collection can be done smoothly without burdening the user, making it a highly efficient, scalable, and robust modality for smartphone user authentication [33], [52].

Another approach in the realm of physiological characteristics, using the front-facing camera on devices, enables capturing the user's facial features and facial attributes (e.g., eyes) [39], [41]. Current face authentication approaches train the system using facial data from a single context or several contexts with no separation. However, camera exposure recognition is essential to improve facial recognition performance in different circumstances. The contingency for elevated accuracy thresholds arises when illumination conditions play a pivotal role in facial image recognition, owing to their substantial impact [39].

MetaEar is a cutting-edge method of modeling and authenticating Ear-Related Transfer Function (ERTF) biometrics from the human ear using Frequency-Modulated Continuous Wave (FMCW) ultrasonics. The system uses FMCW ultrasonic waves and twin microphones to record and analyze the feedback sound wave for extracting ERTF characteristics [48].

C. Pattern Recognition Techniques

Pattern recognition techniques play an essential role in smartphone continuous biometric authentication systems, enabling the automatic identification and classification of patterns in data for efficient and accurate analysis. Recent advances in machine learning algorithms have revolutionized pattern recognition, offering powerful tools for extracting meaningful information from complex data sets. Fig. 3 depicts utilization patterns of classification techniques in continuous multimodal biometric authentication systems based on an SLR.

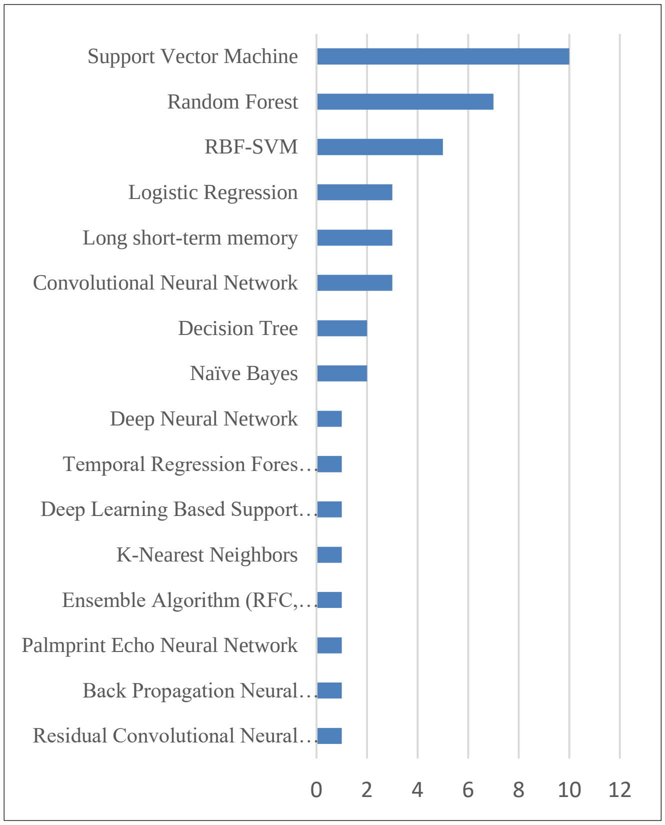

Fig. 3. The utilization patterns of classification techniques in continuous multimodal biometric authentication systems.

The study conducted by Benegui used four different Convolutional Neural Network (CNN) architectures with varying depths as embedding extractors [30]. These networks have a similar structure, using SoftMax activation at the classification layer and Rectified Linear Units (ReLU) at another layer. Experimental results demonstrate the outstanding suitability of the gait-based dataset for the task at hand, enabling the passive collection of gait data and continuous user identification, serving as a robust continuous authentication mechanism.

In addition, CNN shows superior performance compared to traditional machine learning classifiers such as Support Vector Machine (SVM), k-nearest Neighbors, Random Forest, and Linear Discriminant Analysis (LDA) when applied to behavioral characteristics based on routine activities [33]. The inherent time-invariant nature of CNN makes it particularly suitable for processing time series data in behavioral biometrics, such as the analysis of hand movements [42].

The Long Short-Term Memory (LSTM) model undergoes an optimization process to determine the optimal set of parameters for a particular task. Compared to CNN and ConvLSTM architectures, six-layer CNN outperforms ConvLSTM in terms of accuracy and generalization [30]. An LSTM-based architecture is used in the authentication model to capture user behavior patterns while holding their smartphone, regardless of activity. As shown through keystroke dynamics analysis, LSTM classifiers show promising potential in predicting user behavior, even with limited data availability [54].

Unsupervised user verification demonstrates remarkable performance with minimal training time. The authentication system effectively handles various activities and routines using a dedicated single-class SVM model, resulting in exceptional accuracy [37]. Moreover, SVM classifiers are trained on facial characteristics using advanced methods like face warping and textual feature extraction, ensuring precise face identification [41]. The authentication process further incorporates the analysis of touchscreen interactions and subtle micro-gestures, enhancing the overall accuracy and reliability of the system [31].

In other techniques, Random Forest (RF) is often used for prediction and classification because the computational complexity is relatively low, and the training is faster [50]. RF technique is also utilized to identify motion status, touch gesture characteristics, keyboard patterns, and short-term activities. [29], [45], [50]. The pattern recognition field also extensively uses another statistical method called logistic regression. On the other hand, the author favors this option due to its simplicity and dependability and the fact that it is included in the Weka library [29], [39].

D. Discussion

We discovered 13 biometric authenticators that use behavioral and physiological aspects for authentication. Behavioral factors are used most frequently for smartphone authentication, followed by physiological and mixed techniques. In addition, we identified 16 pattern recognition approaches critical for constructing a continuous multimodal biometric authentication system. Fig. 3 depicts the ranked pattern recognition techniques that were used.

Based on these findings, it can be concluded that behavioral traits have been widely implemented in smartphone authentication. The combination of biometric authentication ensures secure and reliable authentication, providing an additional layer of protection for smartphone users. Furthermore, selecting pattern recognition techniques is crucial in continuous biometric authentication systems on smartphones. This ensures the automatic identification and classification of data patterns for efficient and precise analysis.

VI. Conclusion and Future Works

A. Conclusion

The SLR method was employed in this study to investigate the implementation of continuous multimodal authentication in Smartphones. The study's findings revealed a diverse collection of journals across different quartiles, with notable publications discussing continuous authentication in Q1 and Q2 journals. The examination of biometric authenticators revealed a diverse set of methodologies, with behavioral traits being the most often utilized for smartphone authentication. Behavioral variables, such as human movement and customary activities, are used for smartphone authentication, followed by physiological characteristics and a mix of both.

Additionally, the research emphasized the popularity of pattern recognition algorithms, including neural networks based on convolution and long-term and short-term memory models. These showed more extraordinary performance when evaluating behavioral biometrics. Support Vector Machine, Random Forest, and Logistic Regression were also used for classification and prediction. Overall, the study provided insights into the landscape of biometric authentication and pattern recognition techniques in continuous multimodal biometric authentication systems on smartphones.

This research contributes to understanding the implementation of continuous multimodal authentication on smartphones. The findings highlight the importance of behavioral characteristics and the effectiveness of pattern recognition techniques in enhancing security and user authentication. The diverse range of journals and the prevalence of advanced machine-learning algorithms in the field demonstrate significant advancements in this area of research. Future studies can further explore the performance and usability of these authentication methods and investigate new approaches to enhance continuous authentication on smartphones.

B. Limitations and Future Works

The research had certain limitations. Initially, it concentrated primarily on multimodal continuous authentication in smartphones. Second, it only looked at multimodal biometrics, not unimodal biometrics. Future studies could investigate a broader range of devices that require authentication techniques. Furthermore, additional research might focus on unimodal biometrics or compare unimodal and multimodal biometrics across different devices.

Elevating Student Performance Prediction using Extra-Trees Classifier and Meta-Heuristic Optimization Algorithms

Yangbo Li[1]*, Mengfan He[2]
Department of Computer Science and Technology, Henan Institute of Technology, Xinxiang Henan, 453003, China[1]
Office of the President, Henan Institute of Technology, Xinxiang Henan, 453003, China[2]

Abstract—**In the highly competitive landscape of academia, the study addresses the multifaceted challenge of analyzing voluminous and diverse educational datasets through the application of machine learning, specifically emphasizing dimensionality reduction techniques. This sophisticated approach facilitates educators in making data-informed decisions, providing timely guidance for targeted academic improvement, and enhancing the overall educational experience by stratifying individuals based on their innate aptitudes and mitigating failure rates. To fortify predictive capabilities, the study employs the robust Extra-Trees Classifier (ETC) model for classification tasks. This model is enhanced by integrating the Gorilla Troops Optimizer (GTO) and Reptile Search Algorithm (RSA), cutting-edge optimization algorithms designed to refine decision-making processes and improve predictive precision. This strategic amalgamation underscores the research's commitment to leveraging advanced machine learning and bio-inspired algorithms to achieve more accurate and resilient student performance predictions in the mathematics course, ultimately aiming to elevate educational outcomes. Analyses of G1 and G3 showcase the efficacy of the ETRS model, demonstrating 97.5% Accuracy, F1-Score, and Recall in predicting the G1 values. Similarly, the ETRS model emerges as the premier predictor for G3, attaining 95.3% Accuracy, Recall, and F1-Score, respectively. These outcomes underscore the significant contributions of the proposed models in advancing precision and discernment in student performance prediction, aligning with the overarching goal of refining educational outcomes.**

Keywords—Student performance; mathematics; machine learning; Extra-Trees Classifier; Gorilla Troops Optimizer; Reptile Search Algorithm

I. Introduction

A. Background

The achievement of academic success by students is a core aim in education and a crucial component of any country's educational agenda. Emphasizing the significance of quality education as a driver for societal transformation, educational institutions are compelled to give priority to the development of students who excel not only in academic and non-academic evaluations but also acquire vital practical skills to remain competitive in the job market. Education, central to societal progress, reflects the shared aspirations for well-being and advancement [1]. The emphasis on the caliber of students graduating from schools has emerged as a significant worry. As underscored by Spinath [2], [3], academic success occupies a central position, serving as a gauge for intellectual education and an essential requirement for personal and societal well-being. In this context, Martín asserts that academic achievement goes beyond intellectual quotient (IQ), encompassing diverse dimensions to encompass the cognitive, psychomotor, and affective aspects of students' development [4], [5], [6].

The main advantage of data mining is its capability to meticulously analyze large datasets and formulate rules that can attract the interest of pertinent stakeholders. Additionally, it has the potential to unveil previously unknown and valuable insights that significantly enhance decision-making. Machine learning (ML) algorithms, particularly noted for their efficacy in classification tasks, stand as a focal point in various research pursuits [7], [8], [9]. As per the findings of Sharma, Himani, and Kumar [10], decision tree algorithms are widely acknowledged as effective tools for classification purposes. Decision trees, which are structured models comprising root nodes, branches, and leaf nodes, serves the functions of predicting outcomes. These trees exhibit versatility in handling both numerical and categorical data, are easily comprehensible, and can be visually represented. Their pivotal role extends to the identification of group characteristics, exploration of relationships between variables, and application in predicting various educational outcomes, including student performance. Jorda and Raqueno [11] underscore the significance of diverse decision tree algorithms such as C&R Tree, CHAID, C 5.0, and QUEST, emphasizing their role in the development of classification systems [12], [13], [14].

B. Related Works

Many scholars have conducted thorough investigations into the diverse factors that impact student success across different academic levels [15], [16], [17], [18]. Numerous studies in this realm have employed data mining techniques, specifically classification algorithms, to improve the overall quality of higher education systems and to forecast student performance. This section highlights a selection of pertinent studies; particularly those centered on the utilization of decision trees and classification methods in assessing students' academic performance [19], [20], [21], [22], [23], [24], [25], [26], [27], [28], [29].

As an illustration, Al-Radaideh et al. [30] conducted a study proposing a decision tree classification model aimed at assisting school management in selecting appropriate academic tracks for students, thereby streamlining decision-making processes. Thammasiri et al. [31] introduced a model designed to predict inadequate academic performance among freshmen. By combining support vector machines with SMOTE (Synthetic Minority Over-sampling Technique), they achieved an impressive accuracy rate of 90.24%, effectively addressing class imbalance issues. Mustafa et al. [32] utilized the CRISP framework to assess students' data in C++ courses, conducting a comparative analysis of classifiers such as ID3, C4.5 decision trees, and Naive Bayes. The C4.5 decision tree exhibited superior performance, offering insights into the attributes influencing student performance. Nguyen and Peter [33] investigated the efficacy of decision trees and Bayesian networks in forecasting the academic performance of undergraduate and postgraduate students, with their findings indicating the superior performance of decision trees. Sunita and LOBO L.M.R.J [34] showcased the practicality of data mining in the realm of education by employing classification and clustering algorithms to predict student performance and group students accordingly. Bichkar and R. R. Kabra [35] developed classification models geared towards identifying at-risk students among first-year engineering students. Bharadwaj and Pal [36] applied the ID3 decision tree algorithm to predict student divisions based on various academic indicators. Edin Osmanbegovic et al. [37] formulated a model aimed at predicting student academic success, specifically addressing challenges related to data dimensionality. Despite Naïve Bayes achieving the highest accuracy at 76.65%, the model fell short in effectively handling the class imbalance issue. Surjeet and Pal [38] utilized various decision tree algorithms to forecast the performance of first-year engineering students, focusing on the identification of those at risk of failure. Mahfuza and Shovon [13] proposed a hybrid approach that combines clustering and classification to categorize students into high, medium, and low standards, enabling informed decisions about their academic performance and ultimately enhancing their final examination results. Kabakchieva [39] compared data mining algorithms for predicting student performance and classifying students as strong or weak, with the neural network achieving high accuracy for the strong class. Carlos et al. [40] employed machine learning to create a model for predicting student failure, achieving a notable accuracy of 92.7% with the ICRM classifier. The summary of several related studies was reported in Table I.

C. Objective

Employing the Extra-Trees Classifier (ETC) technique, this research had the primary objective of developing a robust Machine learning model for predicting student performance, leveraging data from reliable sources. In creating these models, the study introduced an innovative approach by seamlessly integrating two optimization algorithms: the Gorilla Troops Optimizer (GTO) and the Reptile Search Algorithm (RSA). The decision to integrate these optimization algorithms stems from their complementary strengths. GTO, inspired by gorilla troop foraging behavior, balances global and local search strategies, while RSA adapts to changing environments efficiently. This novel combination of techniques aimed to enhance the accuracy and precision of the predictive model, ultimately contributing to more effective student performance forecasts in an educational context. The ETC model is employed in predicting and classifying student performance due to its robustness and effectiveness. ETC minimizes overfitting, enhances accuracy, and handles diverse data patterns. This model is particularly valuable in educational contexts where the prediction of student outcomes requires a versatile and resilient algorithm capable of capturing nuanced relationships within complex datasets. Subsequently, in Section II, the material and methodology of the research are prepared; Section III contains information about the evaluation methods, results, and discussion of prediction models; and finally, the results of classification models. In the end, Section IV concludes the important findings of the study.

II. MATERIALS AND METHODOLOGY

A. Extra-Trees Classifier (ETC)

Geurts et al. [41] introduced the Extra Trees Classifier as a modification of the Random Forest algorithm. This model, acknowledged as a highly randomized tree classifier or redundant tree classifier, operates through the utilization of an ensemble learning approach. The Extra-Trees algorithm constructs an ensemble of decision or regression trees via the conventional top-down procedure. Its primary distinctions from other tree-based ensemble methods lie in two key aspects: firstly, it randomly selects cut-points for node splits, and secondly, it employs the entire learning sample for the growth of the trees.

The Extra-Trees algorithm employs a randomized splitting procedure for numerical attributes, controlled by parameters K (number of randomly selected attributes at each node) and n_{min} (minimum sample size for node splitting). The method utilizes the full original learning sample multiple times to create an ensemble model with M trees. Predictions are aggregated through majority vote or arithmetic average for classification and regression, respectively. The approach aims to reduce variance by explicit randomization of cut points and attributes, outperforming other methods. Using the full learning sample minimizes bias. Despite a complexity of $N \log N$, the simplicity of the node-splitting procedure contributes to computational efficiency. Parameters K, n_{min}, and M influence attribute selection, noise averaging, and variance reduction, respectively. While adaptable, default settings are preferred for computational advantages and method autonomy.

The process of dividing attributes in Extra-Trees is outlined as follows:

```
Split a node (S)
Input: for the node designated for splitting, present the local learning subset $S$. The resulting output is either a split, denoted as [$a < a_c$], or no result.
– If Stop split(S) is TRUE then return nothing.
– Otherwise select $K$ attributes {$a_1, . . ., a_k$} among all non-constant (in $S$) candidate attributes;
– Draw $K$ splits {$s_1, . . ., s_k$}, where $s_i$= Pick a random split ($S$,$a_i$ ), $\forall_i$= 1, . . ., K;
– Return a split $s_*$ such that Score ($s_*$, S) = maxi=1..., $K$ Score ($s_i$, S)
Pick a random split ($\boldsymbol{S}$,a)
Inputs: a subset $S$ and an attribute $a$
Output: a split
– Let $a^s_{max}$ and $a^s_{min}$ denote the maximal and minimal value of $a$ in $S$;
– Draw a random cut-point $a_c$ uniformly in [$a^s_{max}$, $a^s_{min}$ ];
– Return the split [a < $a_c$].
Stop split ($\boldsymbol{S}$)
Input: a subset $S$
Output: a Boolean
– If |S| < $n_{min}$, then return TRUE;
– If all attributes are constant in $S$, then return TRUE;
– If the output is constant in $S$, then return TRUE;
– Otherwise, return FALSE.
```

B. *Gorilla Troops Optimizer (GTO)*

The genesis of the GTO technique can be traced back to the observation and analysis of social intelligence within gorilla groups in their natural habitats [42]. In this methodology, every gorilla is considered a potential solution, and the optimal solution at each optimization stage is identified as the silverback gorilla. The optimization process is delineated into two key phases: exploration and exploitation. To stimulate exploration, three strategies are implemented, with one of them entailing the migration of gorillas to unexplored areas. The objective of this migration strategy is to augment the exploration process, as elucidated in Eq. (1).

$$GX(t+1) = (UL - LL) \times r_1 + LL, Rnd < O \tag{1}$$

The second approach entails transitioning to a different gorilla group, contributing to the equilibrium between exploration and exploitation, as articulated in Eq. (2).

$$GX(t+1) = (r_2 - C) \times X_r(t) + L \times H, Rnd \geq 0.5 \tag{2}$$

The third tactic involves relocating to the designated site, primarily focused on augmenting the GTO's capacity to explore varied optimization spaces, as elucidated in Eq. (3).

$$GX(t+1) = X(i) - L \times \Big(L \times \big(X(t) - GX_r(t)\big) + r_3 \times \big(X(t) - GX_r(t)\big)\Big), Rnd < 0.5 \tag{3}$$

where, $GX(t+1)$ signifies the potential solution position of a gorilla in the subsequent iteration, while $X(t)$ is the current position vector of the gorilla. Rnd, r_1, r_2, and r_3 are random values in the range of $[0-1]$. The parameter o denotes the probability of opting for the migration strategy to an unfamiliar position and must be predetermined between 0 and 1 prior to initiating the optimization process. X_r represents a randomly chosen member from the gorilla group, while GX_r denotes the potential solution vector position of the gorilla, chosen at random. LL and UL represent the lower and upper limits of the variables, respectively. Additionally, C, L, and H can be defined through mathematical expressions as per Eq. (4) to Eq. (6).

$$C = (\cos(2 \times r_4) + 1) \times (1 - t/\max(t)) \tag{4}$$

$$L = C \times l \tag{5}$$

$$H = Z \times X(t) \tag{6}$$

Here, r_4 signifies a random value within the range of 0 to 1, while l represents a random value within the range of -1 to 1, and Z denotes a random value that ranges from $-C$ to C. If the value of $Rand$ is below p, the first strategy is executed. Conversely, if $Rand$ is greater than or equal to 0.5, the second strategy is applied, and if $Rand$ is less than 0.5, the third strategy is chosen. The optimal solution acquired during the exploration phase is subsequently identified as the silverback.

To enhance exploitation, the GTO methodology incorporates two strategies. The initial strategy entails tracking the silverback, which is the designated gorilla, symbolizing the optimal solution. This strategy is activated when the value of the parameter C exceeds the random parameter W. The silverback assumes the role of a leader guiding other gorillas in foraging for food. This behavior can be expressed mathematically through Eq. (7) and Eq. (8), where, $g = 2^L$.

$$GX(t+1) = L \times M \times (X(t) - X_{sb}) + X(t) \tag{7}$$

$$M = \left(\left|\left(\frac{1}{n}\right)\sum_{i=1}^{n} GX_i(t)\right|^g\right)^{1/g} \tag{8}$$

Here, X_{sb} signifies silverback gorilla.

The alternate exploitation strategy centers around vying for the adult female gorilla. This course is selected when the value of the parameter C falls below the random parameter W. In their native environment, young male gorillas engage in intense competition to win the favor of a female gorilla. This conduct can be mathematically articulated through Eq. (9).

$$GX(t+1) = X_{sb} - (X_{sb} \times Q - X(t) \times Q) \times V \tag{9}$$

$$Q = 2 \times r_5 - 1 \tag{10}$$

$$V = \gamma \times I \tag{11}$$

Here, Q signifies the force of impact, with r_5 representing a random value within the range of $[0-1]$. V is a vector signifying the intensity of aggression during a conflict, and γ is a predetermined value established before initiating the optimization process. I denotes the influence of aggression on the solution's dimensions. The optimal solution derived from the exploitation phase is then assigned the role of the new silverback. This designation could either be retained from the chosen gorilla during the exploration phase or newly selected.

The pseudo-code of GTO is provided below [43]:

Algorithm 1. The pseudo-code of GTO.

```
GTO setting
Inputs: The population size $n$ and maximum number of iterations $T$ and parameters $\gamma$ and $O$
Outputs: The location of the Gorilla and its fitness value
Initialization
Initialize the random population $X_i (i = 1,2,\dots,n)$
Calculate the fitness values of the Gorilla
Main Loop
while (stopping condition is not met) do
    Update the $C$
    Update the $L$
    Exploration phase
    for (each Gorilla ($X_i$)) do
        Update the location of Gorilla
    end for
    % Create group
    Calculate the fitness values of the Gorilla
    if $GX$ is better than $X$, replace them
    Set $X_{sb}$ as the location of $silverback$ (best location)
    % Exploitation phase
    for (each Gorilla ($X_i$)) do
        if ($|C| \geq 1$) then
            Update the location of Gorilla
        else
            Update the location of Gorilla
        end if
    end for
    % Create group
    Calculate the fitness values of the Gorilla
    if New Solutions are better than previous solutions, replace them
    Set $X_{sb}$ as the location of $silverback$ (best location)
end while
Return $X_{BestGorilla}$, $bestFitness$
```

C. Reptile Search Algorithm

The Reptile Search Algorithm (RSA) draws inspiration from the foraging behaviors observed in crocodiles within their natural environment [44]. It operates by alternating between encircling and hunting search phases, with the transition between these phases achieved by dividing the total number of iterations into four segments [45], [46].

1) Initialization phase: *The Reptile Search Algorithm commences by stochastically generating an initial set of solution candidates using the following equation:*

$$X_{ij} = rnd \times (UB - LB) + LB \quad j = 1,2,\dots,n \tag{12}$$

In the initialization matrix (X_{ij}) mentioned earlier, the variable j corresponds to the population size, indicating the number of rows in the matrix. LB and UB denote the lower and upper bound constraints, respectively, and rnd signifies randomly generated values employed in the initialization process.

2) Exploration (Encircling phase): The encircling phase primarily involves navigating an area with a high density of potential solutions. In this phase, movements inspired by crocodile behaviors, such as high walking and belly walking, plays a crucial role. It is essential to emphasize that these movements are not directly focused on capturing prey; instead, their purpose is to explore a wide search space within the optimization process.

$$X_{ij}(\vartheta + 1) = OPT_j(\vartheta) \times \left(-\rho_{(ij)}(\vartheta)\right) \times \varepsilon - \left(R_{ij}(\vartheta) \times rnd\right), \quad \vartheta \leq \frac{N}{4} \tag{13}$$

$$X_{ij}(\vartheta + 1) = OPT_j(\vartheta) \times X_{(r_1,j)} \times ES(\vartheta) \times rnd, \vartheta \leq \frac{2N}{4} and\ \vartheta > \frac{N}{4} \tag{14}$$

Here, $OPT_j(\vartheta)$ represents the optimal solution obtained at the jth position, where ϑ denotes the current iteration number, and N is the maximum number of iterations. $\rho_{(ij)}$ represents the value generated by the hunting operator for the ith solution at the jth position. The parameter ε explains the sensitivity, influencing the exploration accuracy. R_{ij} is utilized to reduce the search space area. The calculations for $\rho_{(ij)}$ and R_{ij} are as follows:

$$\rho_{(ij)} = OPT_j(\vartheta) \times P_{(i,j)} \tag{15}$$

$$\rho_{(ij)} = \frac{OPT_j(\vartheta) - P_{(r_2,j)}}{OPT_j(\vartheta) + \alpha} \tag{16}$$

Here, the variable r_1 is a randomly generated number within the range of $[1 - T]$, where T represents the total count of candidate solutions. $X_{(r_1,j)}$ signifies a randomly chosen position for the jth solution. Similarly, r_2 is another randomly generated number ranging from $[1 - T]$, and α denotes a small-magnitude value. $ES(\vartheta)$ denoted as Evolutionary Sense, is a probability-based ratio. The mathematical expression of Evolutionary Sense can be articulated as follows:

$$ES(\vartheta) = 2 \times r_3 \times \left(1 - \frac{1}{N}\right) \tag{17}$$

In this scenario, the variable r_3 represents a randomly generated numerical value. The calculation of $P_{(i,j)}$ is determined using the following formula:

$$P_{(i,j)} = \varepsilon + \frac{X_{(i,j)} - A(X_i)}{OPT_j(\vartheta) \times (UB - LB) + \alpha} \tag{18}$$

$$AVG(X_i) = \frac{1}{T} \sum_{j=1}^{T} X_{(i,j)} \tag{19}$$

where, $AVG(X_i)$ represents the average position of the ith solution.

3) Exploitation (Hunting phase): The hunting phase involves two key strategies: hunting coordination and cooperation. These strategies play a crucial role in local-scale exploration, resembling the pursuit of optimal solutions, similar to hunting prey. The hunting phase is segmented based on the current iteration number. The hunting coordination strategy operates when the iteration number ϑ is within $\vartheta \leq \frac{3N}{4}$ and $\vartheta > \frac{2N}{4}$, while the hunting cooperation strategy is applied when $\vartheta \leq N$ and $\vartheta > \frac{3N}{4}$. These strategies incorporate stochastic coefficients to explore the local search space and generate optimal solutions systematically. The exploitation phase is guided by Eq. (9) and Eq. (10) to facilitate this process.

$$X_{ij}(\vartheta + 1) = OPT_j(\vartheta) \times P_{ij}(\vartheta) \times rnd,$$

$$\vartheta \leq \frac{3N}{4} \ and \ \vartheta > \frac{2N}{4} \tag{20}$$

$$X_{ij}(\vartheta + 1) = OPT_j(\vartheta) - \rho_{(ij)}(\vartheta) \times \alpha - R_{ij}(\vartheta) \times rnd, \vartheta \leq Nand \ \vartheta > \frac{3N}{4} \tag{21}$$

The RSA process is illustrated in Fig. 1.

D. Data Processing

The principal objective of this study is to formulate a robust methodology for the accurate evaluation of students' academic performance, considering various contextual factors that exert influence. To achieve this goal, meticulous preprocessing of the initial dataset is imperative. In this research, a dataset related to education in Portugal was employed, consisting of 33 distinct characteristics [47], [48] [49]. These features were selected to effectively depict the academic performance of a total of 395 students, considering the information and circumstances of each individual throughout the academic period. The initial step involves the conversion of textual data into numerical values, a foundational prerequisite for the execution of machine learning tasks, facilitating effective data analysis and the application of advanced statistical techniques. The dataset encompasses a diverse range of variables with potential impacts on academic outcomes, including sex, school, urban or rural residency (address), age, family size (famsize), guardian, parental cohabitation status (Pstatus), parental education and occupations (Medu, Fedu, Mjob, and Fjob), home-to-school travel time (traveltime), weekly study time (studytime), school choice motivation (reason), current health status, past class failures (failures), weekday (Dalc), and weekend (Walc) alcohol consumption, engagement in extra paid classes, participation in supplementary education (schoolsup), family educational support (famsup), attendance at nursery school, involvement in extracurricular activities, aspirations for higher education, access to the internet, student absences, involvement in romantic relationships, quality of family relationships, free time, and frequency of socializing. To optimize the dataset's suitability, the preprocessing phase incorporated the application of random permutation (randperm) to mitigate biases, along with normalization procedures aimed at standardizing parameter scales. This research aims to predict and categorize students' academic performance, utilizing the G1 and G3 variables, with G3 representing final grades segmented into four distinct levels: Excellent (16–20), Good (14–16), Acceptable (12–14), and Poor (0–12). The methodology seeks to establish a comprehensive framework for comprehending and assessing academic performance within various contextual factors, contributing to improvements in educational practices and policy development. Fig. 2, presented in the article, illustrates a correlation matrix detailing relationships among input and output variables, highlighting the positive influence of parental education, especially maternal education, on academic performance. Additionally, factors such as daily and weekly alcohol consumption, prior academic failures, and student age demonstrate discernible impacts on school grades, underscoring the critical importance of both study time and parental education as pivotal factors contributing to academic success.

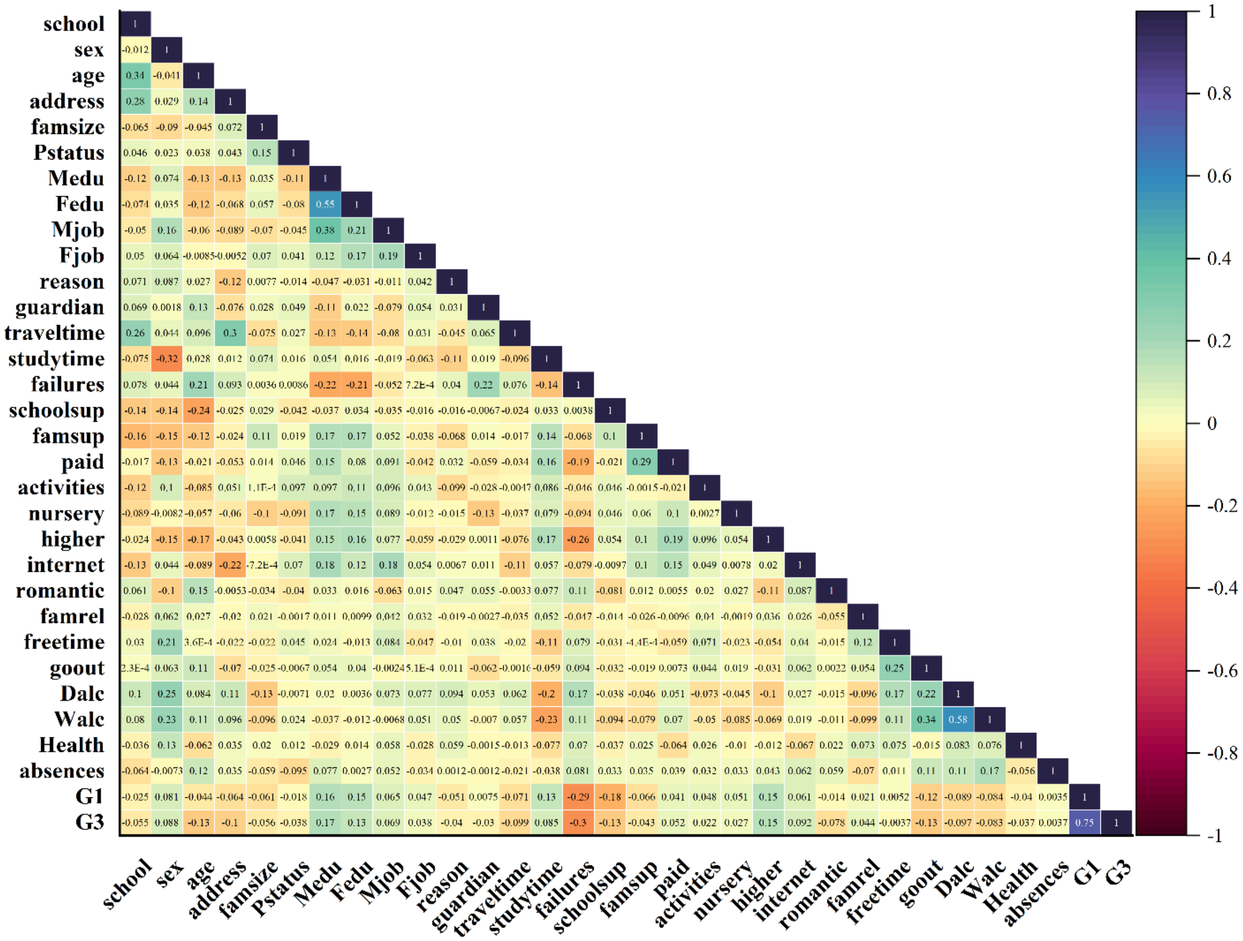

Fig. 2. Correlation matrix for the input and output variables.

III. Results and Discussion

A. Evaluation of Models' Applicability

In the evaluation of classification problems, the metric commonly employed to assess a model's overall performance is Accuracy. This metric relies on four key components: True Positives (TP) for correct positive predictions, True Negatives (TN) denoting accurate negative predictions, False Positives (FP) representing inaccurate positive predictions, and False Negatives (FN) indicating incorrect negative predictions. However, the applicability of Accuracy diminishes in scenarios involving imbalanced data, where it tends to favor the majority class, limiting its interpretability. To overcome this limitation, three additional evaluation metrics, including Recall, F1-Score, Precision, Matthew’s correlation coefficient (MCC), and Area under the curve (AUC), are frequently utilized. These metrics offer a more nuanced understanding of a model's performance, particularly in the presence of imbalanced class distributions. Expressed through mathematical equations, typically numbered from 22 to 26, these metrics collectively contribute to a refined and comprehensive assessment of the effectiveness of a classification model.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (22)$$

$$Precision = \frac{TP}{TP+FP} \quad (23)$$

$$Recall = TPR = \frac{TP}{P} = \frac{TP}{TP+FN} \quad (24)$$

$$F1\_score \ = \frac{2\times Recall \times Precision}{Recall+Precision} \quad (25)$$

$$MCC \ = \frac{(TP*TN)-(FP+FN)}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}} \quad (26)$$

B. Hyperparameters and Convergence Results

In machine learning, hyperparameters, external configurations that encompass elements such as learning rates and regularization strengths, play a pivotal role in shaping a model's behavior. Unlike parameters, hyperparameters are predetermined and are not directly acquired from the data. The optimization of model performance hinges on the essential process of tuning hyperparameters, demanding experimentation, and the application of optimization techniques. Table II meticulously delineates the hyperparameter values associated with ETRS and ETGT models, specifically max_depth, min_samples_split, min_samples_leaf, and max_leaf_nodes. This comprehensive presentation significantly bolsters the transparency and reproducibility of models in machine learning research, offering crucial insights for a more profound comprehension and accurate replication of model configurations.

TABLE II. RESULTS OF HYPERPARAMETERS

Target	Hyperparameter	ETRS	ERGT
G1	max_depth	24	722
	min_samples_split	0.028	0.511
	min_samples_leaf	0.0125	0.092
	max_leaf_nodes	250	10
G3	max_depth	275	975
	min_samples_split	0.001	0.234
	min_samples_leaf	0.0015	0.0631
	max_leaf_nodes	4790	10

This research endeavors to optimize the Extra-Trees Classifier's (ETC) hyperparameters, tailoring its performance to specific datasets and problem domains. The optimization process involves utilizing the Gorilla Troops Optimizer (GTO) and Reptile Search Algorithm (RSA), representing a substantial advancement in enhancing the predictive capabilities of this foundational machine learning algorithm. Evaluating the optimization performance involves assessing how selected algorithms impact the Accuracy of ETC through iterations. Fig. 3 depicts two convergence curves, namely ETRS and ETGT, using a stair form with four steps of 50 iterations each. In G1 prediction, ETRS initiates with lower accuracy, but within the first 90 iterations, it consistently outperforms ETGT. The dynamics reverse in the second stage, and after the 90th iteration, both models perform similarly. Notably, around the 125th iteration, ETRS exhibits a marked increase in Accuracy. Conversely, in G3 estimation, both models start with similar Accuracy values. ETRS outperforms ETGT from 0 to 25 iterations, and then ETGT surpasses ETRS from 25 to approximately 75 iterations. Between 75 and 120 iterations, the performance of both models aligns. After the 125th iteration, ETRS experiences a distinctive surge, ultimately concluding the convergence process with a higher accuracy rate than the ETGT model.

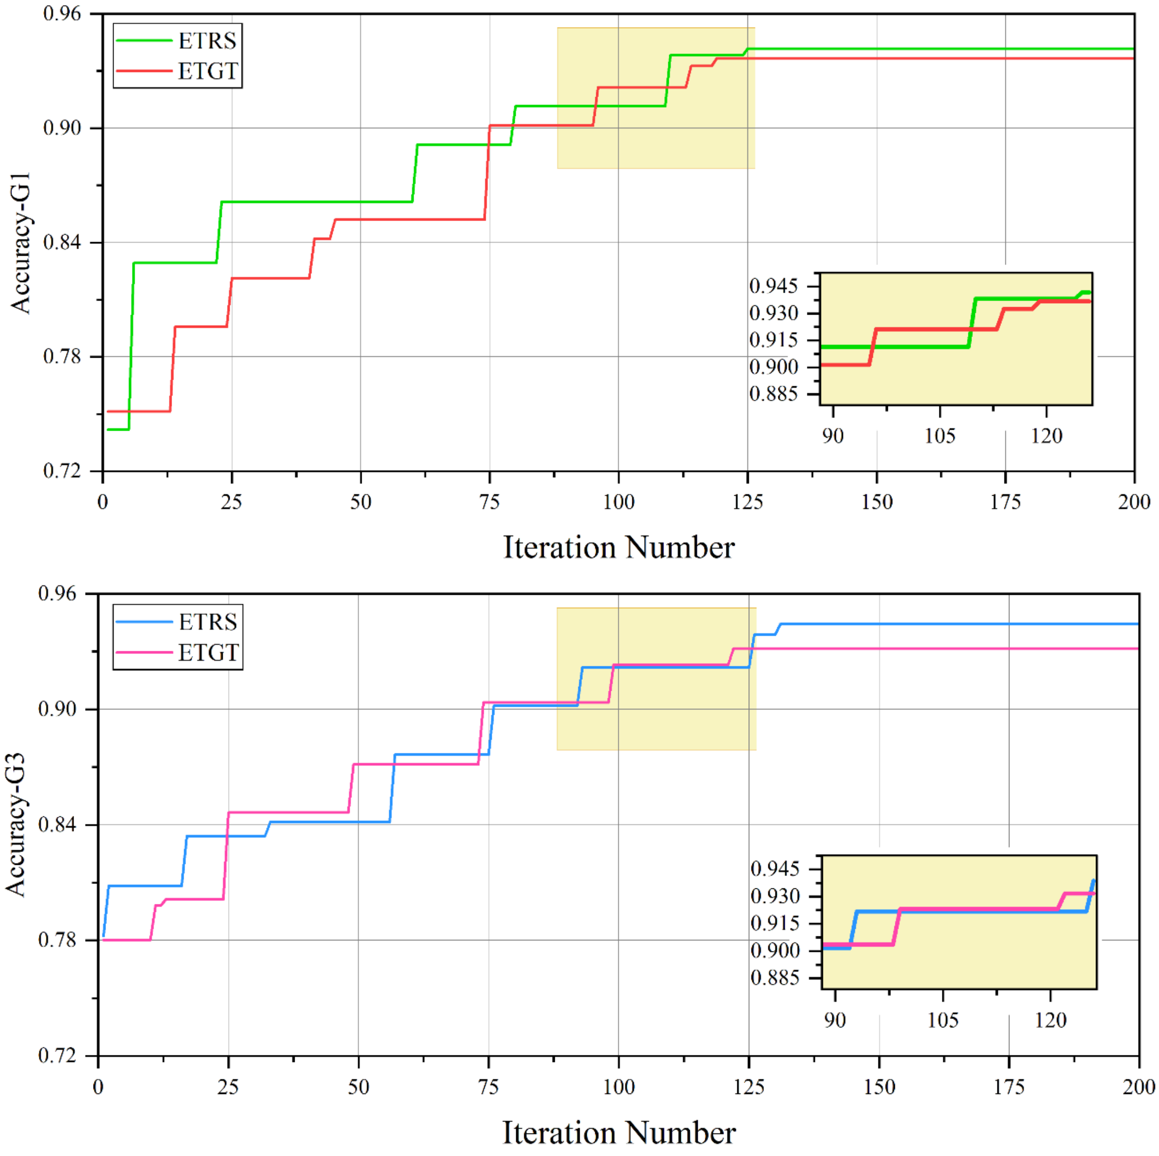

Fig. 3. Convergence curve of models. Prediction and classification results.

In the pursuit of predicting future academic achievements in mathematics through machine learning algorithms, this investigation integrates a diverse array of student information, with a specific emphasis on their short-term and final grades (G1 and G3). The dataset assumes a pivotal role in the training and evaluation of three models based on Extra-Trees Classifier (ETC), namely ETC, ETRS, and ETGT. Within this section, the study systematically computes performance metrics such as Accuracy, Precision, Recall, F1-score, MCC, and AUC at each prediction stage. This meticulous analysis aims to discern the most effective prediction model, offering valuable insights for enhancing students' academic success. All relevant metric values, encompassing all, train, test, and model, are detailed in Table III and illustrated in Fig. 4.

Regarding G1 prediction, ETRS and ETC exhibit the strongest and weakest prediction performance, achieving maximum and minimum Accuracy values of 0.975 and 0.839, respectively. ETRS attains maximum Precision, Recall, F1-score, MCC, and AUC values of 0.976, 0.975, 0.975, 0.957, and 0.931, affirming its high accuracy in positive predictions. The performance of the other hybrid model (ETGT) aligns with ETRS in the training phase Accuracy but experiences a lower value in the testing phase. For G3 prediction, the comparison among the three models reveals ETRS as the strongest predictor with maximum Accuracy, Recall, and F1-score values of 0.953 and 0.921 for MCC. ETGT, with a 0.7% lower Accuracy, secures the second position in the ranking when compared to ETC.

Accuracy-G3

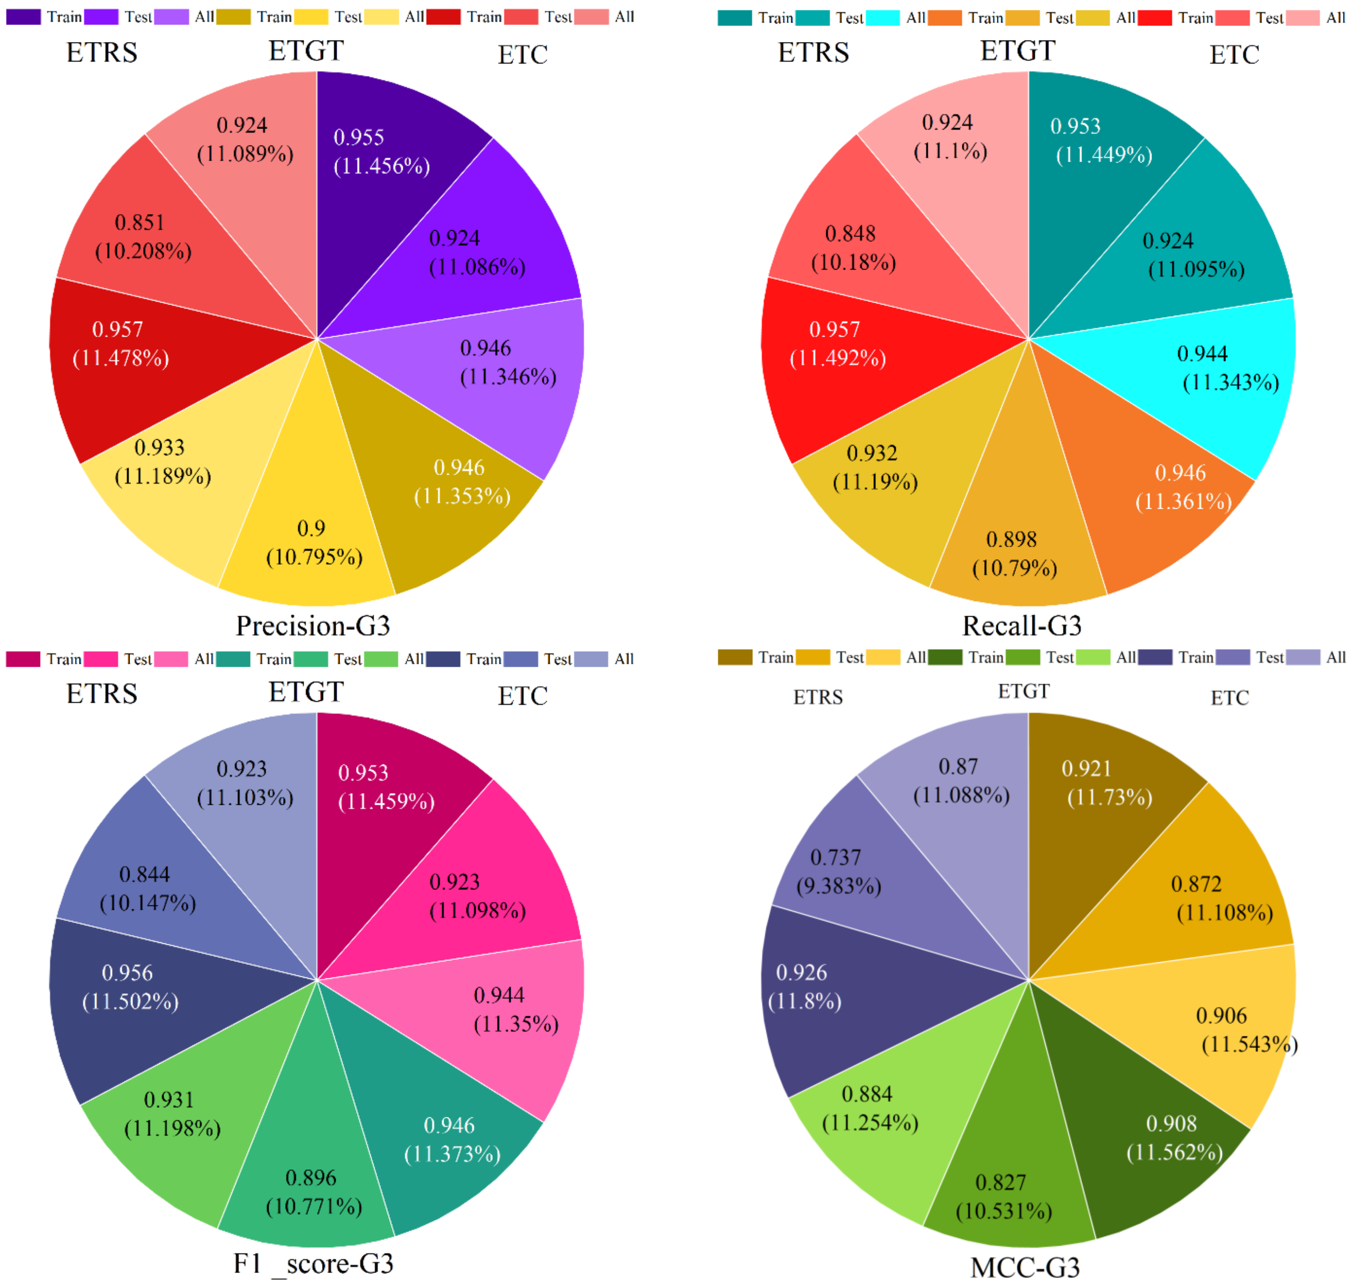

Fig. 4. Pie chart plot for the evaluation of developed models.

Tables IV and V presents the Precision, Recall, F1_score, MCC metrics for students categorized by G1 and G3 grades. These tables offer insights into the model's performance, revealing its accuracy in positive predictions, ability to capture true positives, and overall effectiveness in classifying students based on academic performance levels.

1) G1

a) Excellent: This cohort constitutes around 10% of the dataset, featuring 41 high-achieving students. Despite the ETC and ETRS models exhibiting impeccable Precision (1), the optimized ETGT model shows a slight difference of approximately −5.5%. However, with a Recall value of 0.8293, the ETGT model excels in accurately identifying instances within this top-performing group, surpassing the other models.

b) Good: Among the 54 students in this group, the ETGT model emerged as the superior classifier, achieving Precision, Recall, and F1_score values of 0.9444. Notably, ETRS exhibited the weakest performance based on Precision values, whereas, considering MCC, Recall, and F1-Score, the ETC model demonstrated the least optimal performance levels.

c) Acceptable: The ETRS model showcased superior applicability compared to other models, registering maximum values for all metrics (Precision = 0.984, Recall = 0.912, F1-Score = 0.947, and MCC=0.928). In contrast, the ETGT hybrid model occupied the last position, exhibiting the lowest values across all metrics.

d) Poor: This group pertains to students who have faced academic failure, and the 232 students classified within this category demand heightened institutional focus for improvement. Notably, the performance of all models in classifying this group proves to be optimal, surpassing the other three classes with Precision exceeding 90%. Once again, ETRS stands out as the best model, exhibiting the highest metric values in this context.

TABLE IV. EVALUATION INDEXES OF THE DEVELOPED MODELS' PERFORMANCE IN G1

Model	**Grade**	**Index values**			
		Precision	***Recall***	***F1-score***	***MCC***
ETC	Excellent	1.000	0.805	0.892	0.873
	Good	0.878	0.796	0.835	0.812
	Acceptable	0.922	0.868	0.894	0.892
	Poor	0.924	0.991	0.956	0.887
ETRS	Excellent	1.000	0.781	0.877	0.937
	Good	0.839	0.870	0.855	0.831
	Acceptable	0.984	0.912	0.947	0.928
	Poor	0.947	0.996	0.971	0.872
ETGT	Excellent	0.9444	0.8293	0.8831	0.847
	Good	0.9444	0.9444	0.9444	0.935
	Acceptable	0.8923	0.8529	0.8722	0.906
	Poor	0.9458	0.9784	0.9619	0.873

2) G3

a) Excellent: This subset comprises 40 high-achieving students, representing nearly 10% of the entire dataset under scrutiny. While the Precision values imply that the standalone ETC model showcases flawless predictive capability with a score of 0.971, the optimized models exhibit slightly higher scores (less than 1%). However, a thorough evaluation based on MCC, Recall and F1- score underscores the superiority of the ETRS model, attaining values of 0.883 0.9 and 0.9351.

b) Good: Among this cohort of 60 students, representing 15% of the total 395 studied students, the ETGT model showcased superior performance, particularly evident in Precision values. Furthermore, a comprehensive evaluation considering MCC, Recall and F1-Score affirmed the model's excellence, boasting MCC, Recall and F1-Score values of 0.9, 0.8667 and 0.9123, respectively.

c) Acceptable: Upon scrutinizing the outcomes, it is apparent that the Reptile Search Algorithm (RSA) outperformed the Gorilla Troops Optimizer (GTO) in optimizing the Extra-Trees Classifier (ETC) for G3 classification. The RSA demonstrated higher success, yielding a Recall of 0.9516 and an F1-score of 0.908.

d) Poor: In the classification of students within the Poor category, the ETRS model demonstrated superior performance among the three models. It achieved maximum values across all metrics, notably excelling in the Recall evaluator with a value of 0.9828.

TABLE V. EVALUATION INDEXES OF THE DEVELOPED MODELS' PERFORMANCE IN G3

Model	**Grade**	**Index values**			
		Precision	***Recall***	***F1-score***	***MCC***
ETC	Excellent	0.971	0.825	0.892	0.856
	Good	0.895	0.850	0.872	0.850
	Acceptable	0.885	0.871	0.878	0.885
	Poor	0.934	0.974	0.954	0.884
ETRS	Excellent	0.973	0.9	0.9351	0.883
	Good	0.9245	0.8167	0.8673	0.847
	Acceptable	0.8551	0.9516	0.908	0.942
	Poor	0.9703	0.9828	0.9765	0.929
ETGT	Excellent	0.9722	0.875	0.9211	0.855
	Good	0.963	0.8667	0.9123	0.900
	Acceptable	0.8852	0.871	0.878	0.880
	Poor	0.9303	0.9742	0.9518	0.914

C. Discussion

1) G1: In Fig. 5, the visual representation illustrates the distribution of students across categories, enabling a comprehensive comparison between measured data and the outcomes of classification effectiveness. Specifically focusing on forecasting student performance in G1 scores, individual graphs for each category (Poor, Acceptable, Good, and Excellent) are presented. It is noteworthy that, as per the studied dataset, the total number of students amounts to 395. The subsequent sections meticulously evaluate the models based on recorded figures, revealing 232 individuals in the Poor category, 68 in the Acceptable category, 54 in the Good category, and 41 in the Excellent category. The ETRS model emerges as the most effective classifier for the Poor and Acceptable categories, showcasing precise predictions. However, in the Good and Excellent groups, notable differences are observed between the two hybrid models, with ETRS displaying weaker performance in classifying datasets for these higher-performing groups.

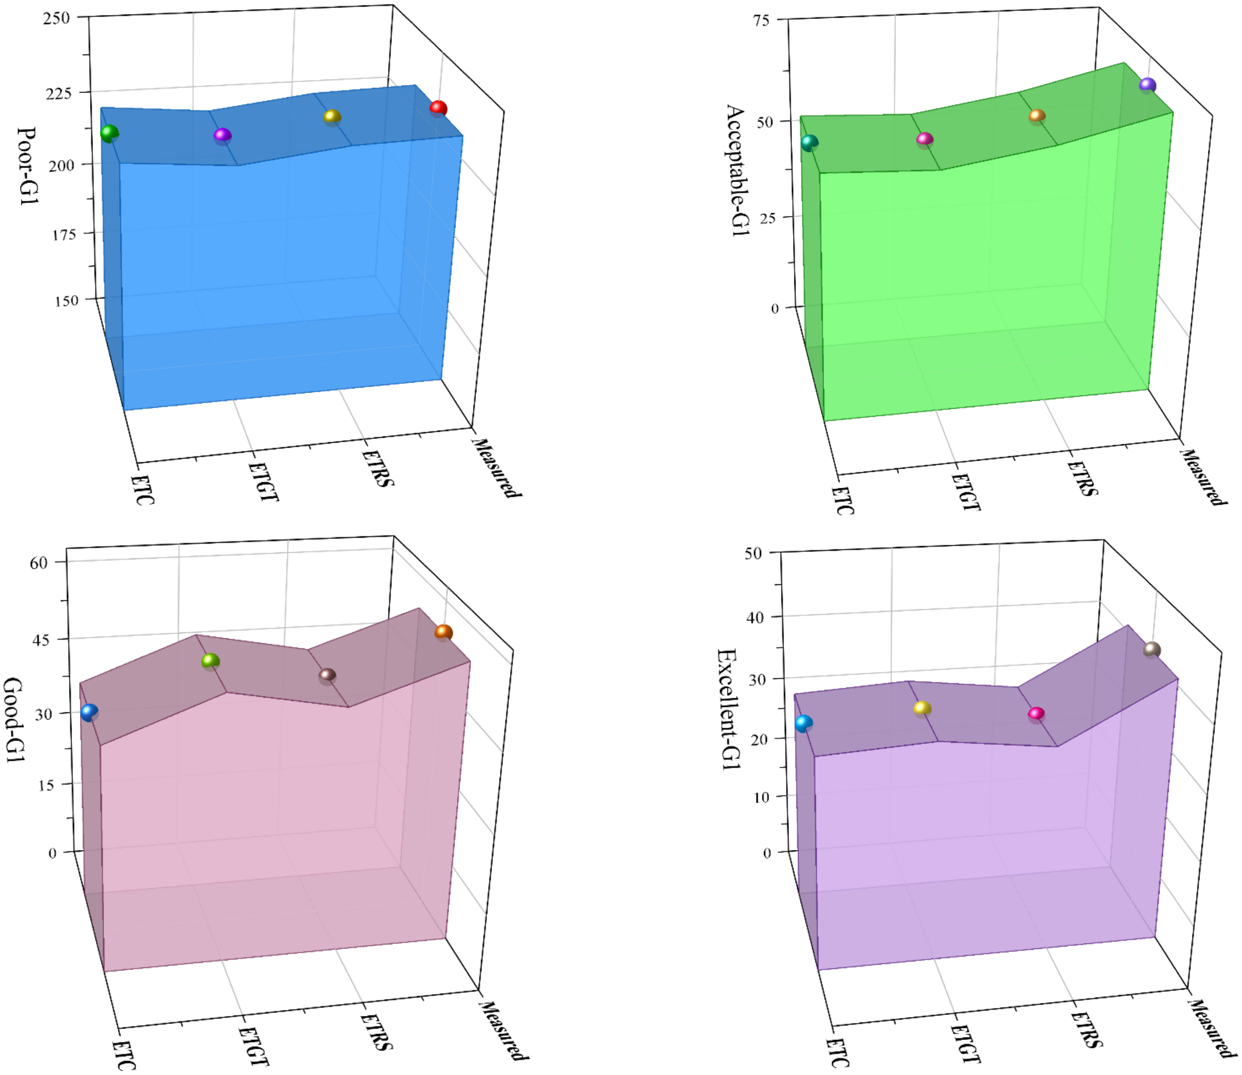

Fig. 5. 3D wall plot for the developed models' accuracy for G1.

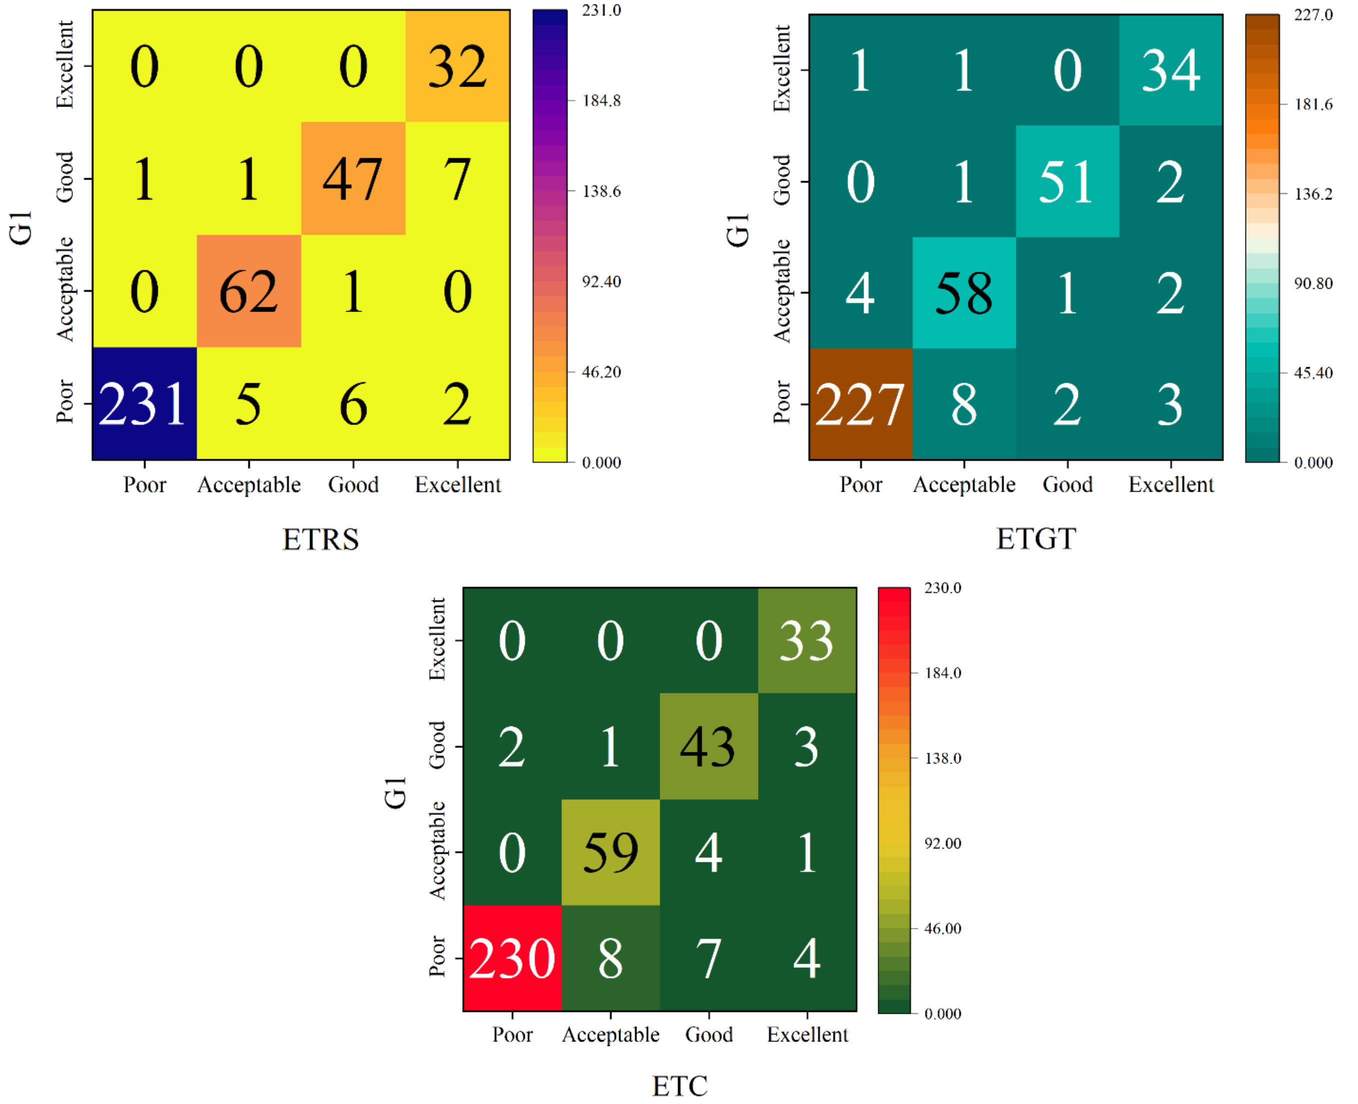
Fig. 6 presents a confusion matrix, offering insights into the accurate categorization of students and instances of misclassifications. Within the ETRS model, 372 students were accurately classified across grades, including 32 in Excellent, 47 in Good, 62 in Acceptable, and 231 in Poor, with 23 misclassifications. In contrast, the ETGT model had 25 misclassifications, while the straightforward ETC model accurately classified 365 students and misclassified 30 students.

2) G3: According to Fig. 7, the recorded student figures for the Poor, Acceptable, Good, and Excellent categories were 233, 62, 60, and 40, respectively. Interestingly, the standalone ETC model demonstrated superior performance in the Poor and Good categories compared to the two hybrid models. Subsequently, the ETRS model emerged as the more effective classifier, excelling in the categorization of students into Excellent and Acceptable groups.



ETRS

G1	Poor	Acceptable	Good	Excellent
Excellent	0	0	0	32
Good	1	1	47	7
Acceptable	0	62	1	0
Poor	231	5	6	2

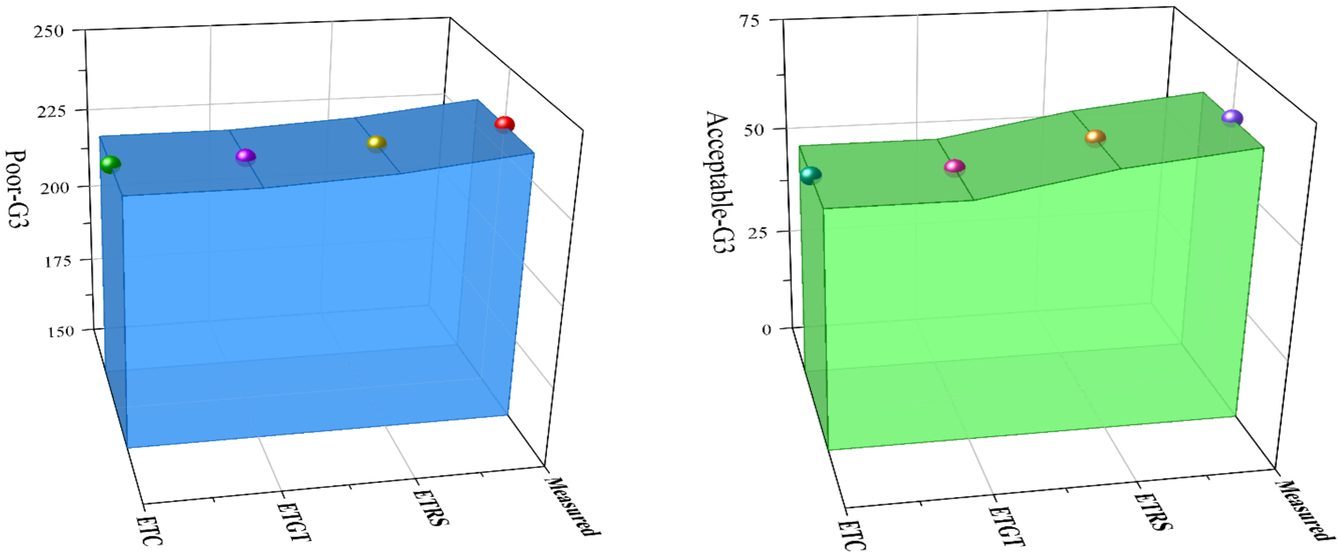
ETGT

G1	Poor	Acceptable	Good	Excellent
Excellent	1	1	0	34
Good	0	1	51	2
Acceptable	4	58	1	2
Poor	227	8	2	3

ETC

G1	Poor	Acceptable	Good	Excellent
Excellent	0	0	0	33
Good	2	1	43	3
Acceptable	0	59	4	1
Poor	230	8	7	4

Fig. 6. Confusion matrix for each model’s accuracy for G1.



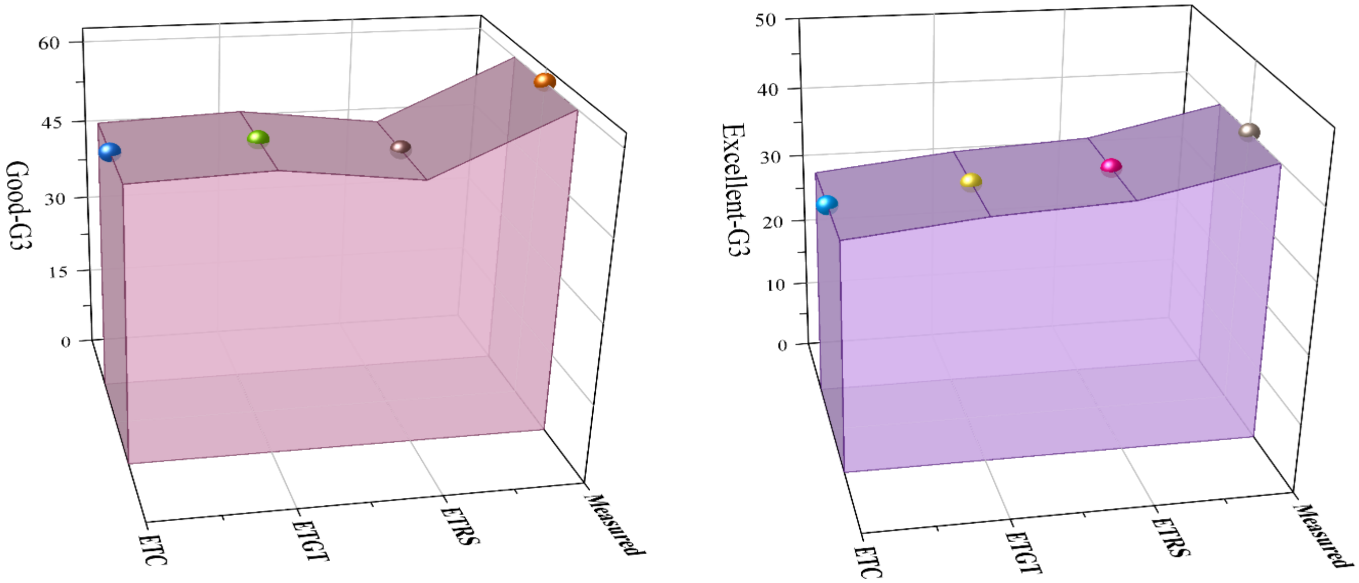


Fig. 7. 3D wall plot for the developed models' accuracy for G3.

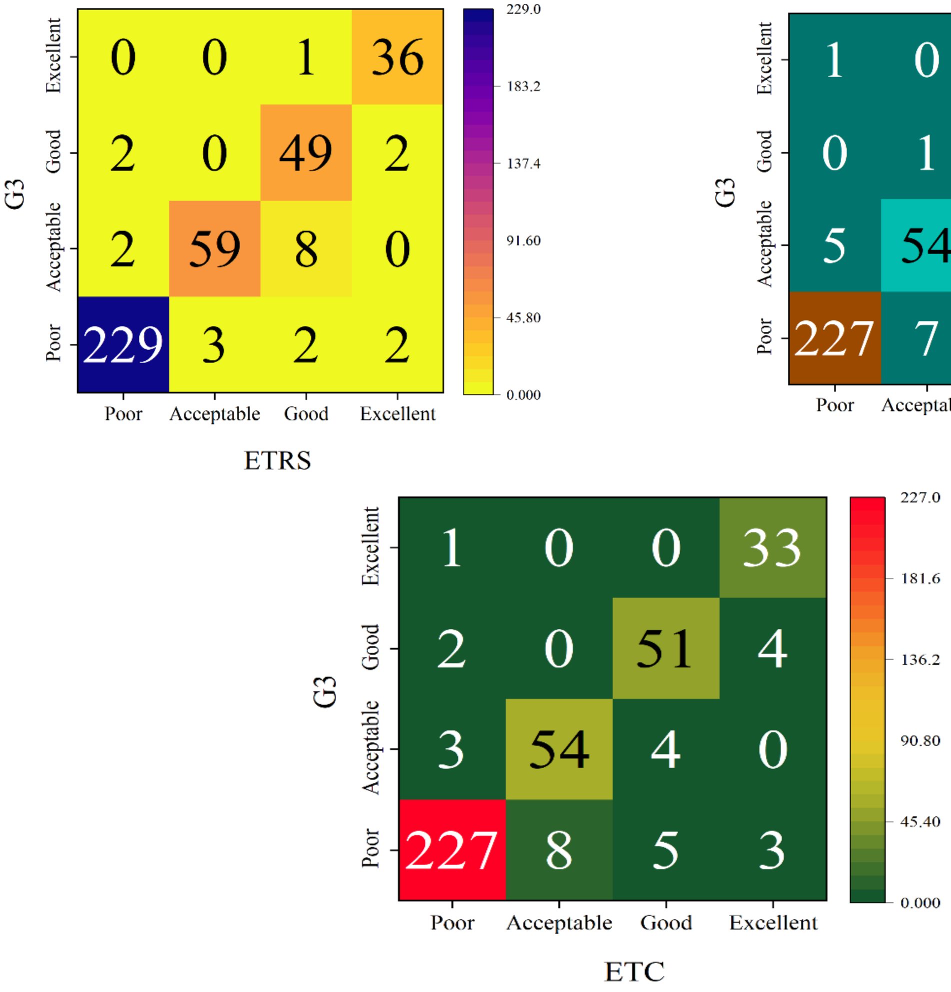

Fig. 8. Confusion matrix for each model's accuracy for G3.

Examining Fig. 8, the ETRS model accurately categorized 373 students into their respective grades, with only 22 misclassifications. In contrast, the ETGT model achieved 368 correct predictions but experienced 27 misclassifications. A thorough comparison reveals that the ETRS model outperformed both the ETGT and ETC models in terms of overall performance.

D. *Comparing Previous Studies vs. Present Research Study*

Table VI summarizes the results of four existing studies in the field of student performance. According to these works, the highest accuracy was related to the employment of the DTC model in the Nguyan and Peter's study [33] with 82%, while in the present study, the combination of ETC model and RSA algorithm, achieved high value of 0.975 for G1 and 0.953 for G3. As can be seen, this work reached the highest accuracy among others.

TABLE VI. COMPARING RESULTS OF EXISTING STUDIES AND PRESENT WORK

Author (s)	**Models**	**Accuracy**
Kabakchieva [39]	DTC	72.74%
Bichkar and R. R. Kabra [35]	DTC	69.94%
Nguyen and Peter [33]	DTC	82%
Edin Osmanbegovic et al. [37]	NBC	76.65%
Present study for G1	ETRS	0.975
Present study for G3	ETRS	0.953

E. *Generelizability and Limitation of Proposed Model*

It is acknowledged that our study was conducted on a specific dataset and that the results may not be directly applicable to other educational contexts. However, it is believed that the potential to be generalized to other settings is possessed by the proposed approach of combining the ETC model with optimization algorithms, as long as the following conditions are met: The data is sufficiently large and representative of the target population The data contains relevant features that can capture the factors influencing students' academic performance The data is preprocessed and cleaned to ensure its quality and validity The optimization algorithms are tuned and adapted to the characteristics of the data.

The optimization algorithms are powerful tools that can improve the performance of predictive models, but they also have some limitations that need to be taken into account. Some of the common limitations and potential drawbacks of optimization algorithms are then discussed, such as:

- The dependence on the quality and quantity of the data. The data is relied on by optimization algorithms to learn and optimize the objective function, but the data may not be sufficient, representative, or accurate enough to capture the true complexity and variability of the problem domain. This may lead to overfitting, underfitting, or bias in the optimization results. Iterative processes are often involved by optimization algorithms that require a large amount of computation and memory resources, especially for high-dimensional and nonlinear problems.
- This may limit the applicability and efficiency of the optimization algorithms in real-world scenarios, where time and space constraints are important factors.
- The sensitivity to the choice of parameters and initial conditions.
- Optimization algorithms often have several parameters and initial conditions that need to be specified by the user or tuned by some methods.
- The convergence, stability, and quality of the optimization results may have a significant impact on these parameters and initial conditions, but they may not be easy to determine or adapt to different problems or datasets.
- The lack of guarantees and robustness.

IV. CONCLUSION

In the context of education, the deployment of data-driven predictive models takes center stage in this investigation. It accentuates the critical need to integrate both qualitative and quantitative factors for the prediction and evaluation of students' academic performance. Illustrating the effectiveness of data mining methodologies like clustering, classification, and regression, the study addresses the multifaceted challenges proactively encountered by undergraduate students. The insights gleaned offer valuable guidance for policymakers, educational institutions, and students alike, with the shared objective of enhancing future academic outcomes. Moreover, the study introduces a cutting-edge strategy by merging the Extra-Trees Classifier (ETC) model with optimization algorithms, namely Gorilla Troops Optimizer (GTO) and Reptile Search Algorithm (RSA). This innovative approach demonstrates the potential of combining machine learning techniques and optimization algorithms to enhance the precision and effectiveness of predictive models. The outcome is a resilient toolkit designed to tackle the dynamic challenges inherent in students' academic journeys. The comprehensive evaluation undertaken in the study, involving the division of models into training and testing sets, unveils the considerable potential of these hybrid models to augment the classification capabilities of the ETC model. This improvement manifests in noteworthy enhancements in Accuracy and Precision. Upon scrutinizing the results, it becomes apparent that the recognition of the potential to significantly enhance the classification capabilities of the ETC model by these hybrid models is growing. In the context of G1 values, the enhancement of Accuracy, Recall, and F1-Score, achieved through the implementation of RSA and GTO optimization algorithms on the ETC model, was notable. The utilization of RSA and GTO resulted in a 1.56% improvement. The ETRS model, showcasing a remarkable Accuracy rate of 0.975, effectively and precisely classified the majority of students.

On the other hand, the ETGT and ETC models experienced misclassification rates of 6.33% and 7.6%, respectively. Turning attention to G3 values, the application of RSA and GTO optimization algorithms to the ETC model yielded significant improvements in all metrics' values in the testing phase. Nonetheless, this application led to a small reduction in the results of the training phase. The rate of Accuracy values' enhancement for RSA was 9.09%, and for GTO was 6.02% in the testing phase. When the 395 students were categorized based on their final grades, the prowess of the RSA algorithm in enhancing classification Accuracy became evident. The ETRS model demonstrated an impressive Accuracy rate of 0.953, adeptly classifying the majority of students. These findings underscore the efficacy of both RSA and GTO optimization algorithms in refining the predictive capabilities of the ETC model. Notably, the RSA algorithm exhibited a particularly commendable performance, showcasing its exceptional ability to enhance Accuracy, especially in the classification of students based on final grades (G3). The results suggest that the integration of these optimization algorithms holds promise for refining and optimizing the performance of models in educational contexts, contributing to more accurate and reliable student classifications.

Abstract—**In light of the explosive growth of drones, it is more critical than ever to strengthen and secure aerial security and privacy. Drones are used maliciously by exploiting some gaps in artificial intelligence and cybersecurity. Airborne target detection and tracking tasks have gained paramount importance in various domains, encompassing surveillance, security, and traffic management. As airspace security systems aiming to regulate drone activities, anti-drones leverage mostly artificial intelligence and computer vision advances in the used detection and tracking models to perform effectively and accurately airborne target detection, identification, and tracking. The reliability of the anti-drone systems relies mostly on the ability of the incorporated models to satisfy an optimal compromise between speed and performance in terms of inference speed and used detection evaluation metrics since the system should recognize the targets effectively and rapidly to take appropriate actions regarding the target. This research article explores the efficacy of DeepSort algorithm coupled with YOLOv7 model in detecting and tracking five distinct airborne targets namely, drones, birds, airplanes, daytime frames, and buildings across diverse contexts. The used DeepSort and Yolov7 models aim to be used in anti-drone systems to detect and track the most encountered airborne targets to reinforce airspace safety and security. The study conducts a comparative analysis of tracking performance under different scenarios to evaluate the algorithm's versatility, robustness, and accuracy. The experimental results show the effectiveness of the proposed approach.**

Keywords—Real-time detection; target tracking; anti-drone; Artificial Intelligence; Computer Vision

I. Introduction

The importance of addressing aerial privacy and security issues associated with drones is growing steadily, emphasizing the critical importance and need for reliable target detection and tracking models for effective airspace security systems, such as anti-drone systems.

The deployment of an anti-drone system, which is known also as a counter-drone system depends mostly on the performance of the detection and tracking modules to detect and identify the most encountered airborne targets to avoid triggering false alarms [1], [2]. It is important to note that the detection and identification tasks are very crucial for the success of the anti-drone process and mainly to avoid neutralizing friendly airborne targets such as birds. Thus, the anti-drone system should recognize the target properly without confusion that could cause weighty damage during the interception phase [3]. Airborne target detection and tracking is crucial in numerous applications, including defense, civilian security, and urban planning. An anti-drone system's effectiveness depends significantly on the detection of the encountered airborne targets [3], [4], [5]. It is important that an anti-drone recognizes and distinguishes between the main types of airborne targets. They share the same airspace and altitudes; mostly the low altitude airspace up to 32 000ft as an upper limit. Due to their similarity, recognizing flying targets at this altitude becomes a real challenge, which increases the probability of false detection. To reinforce and improve the anti-drone process, there is a need to develop suitable detection and tracking models able to meet the requirements and the existing needs. There are several challenges related mainly to the complexity of recognizing effectively and rapidly drones and other airborne targets present in the sky sharing many characteristics with drones that mislead the system. Further, the research tasks related to tracking multiple airborne targets have not been thoroughly studied in the existing literature.

In this study, we aim to develop an advanced detection and tracking model that can identify and track the most common targets in the sky. Computational experiments are conducted through the training, validation, and testing of a model on real-world data. This model is practical based on computational results. Therefore, integrating DeepSort with YOLOv7 is promising due to its real-time object detection capabilities and tracking precision. In addition, using DeepSort for tracking coupled with YOLOv7 for detection offers a significant approach compared to individual applications of these models. This research article aims to contribute to advancing airborne target tracking technology, evaluating the DeepSort with YOLOv7 algorithm's effectiveness in tracking diverse targets under varying scenarios. In the following, Section II provides a summary of the research studies on airborne target detection and tracking, whereas the solving methodology and experimental setup are presented in Section III. The experimental details and results are highlighted in Section IV. We conclude by discussing the advantages and limitations of the proposed model in Section V.

II. Literature Review

This section delineates existing methods for airborne target tracking, emphasizing the advancements and limitations. It covers various algorithms and their applications in tracking airborne targets.

The rise of Artificial Intelligence (AI) has improved many conventional applications, systems and tasks in several domains such as, autonomous cars, smart cities, smartphones, smart truck distribution [6] and pandemic detection [7].

Recently, the field of airborne targets detection and tracking has witnessed significant advancements, driven by the outstanding rise of drones across various sectors. Several research studies have addressed the challenges and risks posed by the proliferation of drones, necessitating the development of robust anti-drone systems capable of accurate detection and tracking.

In study [8], the authors present the small drone tracking results using the radar-based range estimation, as well as the receding horizon tracking model of unauthorized drones through the use of the receding horizon maximization technique and the fisher information matrix predictive model. Combining these two approaches yields the best localization results. The tracking approach proposed in study [9] uses a time difference of arrival estimation algorithm based on Gauss priori probability density functions with Kalman filters. The combination of these models achieved good results for drone tracking. Also, the paper in [10] has proposed a tracking model which analyses the generated acoustic signatures of the drones using beamforming algorithm. The conducted experiments show that depending on the type of the drones, they can be tracked up to 250 meters. Further, a radar tracking and detection method based on phase-interferometry and joint range-Doppler-azimuth processing is presented in study [11]. All of the extracted features from the developed model are used to classify drones. Another drone position tracking proposed in study [12] uses the received signal strength indication (RSSI) signals to estimate the distance and angle of the target to track the aerial target. It uses the estimated distance and angle to gradually track the target through the incorporation of CDQA and ADCA algorithms. The implementation of the proposed approach is not implemented on real environment.

The combination of DeepSort and Yolo has been used in different detection and tracking applications. The authors in study [13] have used a combination of YOLOv3 and RetinaNet for generating detections in each frame along with DeepSort algorithm to track multiple objects from a drone-mounted camera. Comparing the results of the experiment with the existing state-of-the-art models, the detection and tracking combination shows competitive performances on VisDrone 2018 dataset. Similarly, the paper [14] has proposed to use Yolov4 to detect and localize vehicles within the restricted zone along with DeepSort to track them to reinforce aerial surveillance.

To the best of our knowledge, there has been no study that has utilized DeepSort in conjunction with YOLOv7 to detect and track multiple airborne targets specifically for deployments in anti-drone systems.

However, the existing studies on airborne tracking have shown a limited exploration of the specific research aspect addressed in this study, specially tracking the most common airborne targets. The majority of existing research in this domain has predominantly concentrated on drone detection only, with comparatively less emphasis on the comprehensive investigation of the aspect central to our research. Motivated by these limitations and the need for a comprehensive tracking approach, this paper proposes a novel DeepSort algorithm integrated with the YOLOv7 detection model. By combining the real-time detection capabilities of YOLOv7 with the robust object association and tracking features of DeepSort, our proposed methodology aims to address the existing gaps and improve the state-of-the-art in airborne targets detection and tracking.

III. Solving Methodology

In this study, we propose the use of DeepSort algorithm with the YOLOv7 model for detecting and tracking the most encountered airborne targets. This methodology section outlines the dataset used, model training process, hyperparameters, and evaluation metrics.

A. Data Collection

Our developed detection and tracking models are trained on the most encountered airborne targets in the sky which anti-drone systems should recognize rapidly and effectively without causing false alarms. We have gathered a diverse dataset containing video and images with labeled bounding boxes around the targets of interest. The airborne targets in the dataset comprise drones, birds, airplanes, daytime frames, and buildings, which reflects the complexity of real-world detection and tracking scenarios. Indeed, we have trained our detection on five airborne target classes, namely drones, birds, airplanes, dayframes, and buildings. The images are collected mainly from [15], [16], [17] and annotated according to the Yolo format: object class, x, y, width, and height in the corresponding annotation text files. Following, we have used videos from [18] to perform the tracking process. The provided videos highlight mostly drones in different contexts and under different conditions Furthermore, the used dataset ensures variability in lighting conditions, backgrounds, sizes, orientations, and occlusions to improve the used algorithm's performance and robustness.

B. DeepSort Model

Deep Simple Online and Real-time Tracking (DeepSort) is primarily a tracking model that works in conjunction with single-shot and two-shot object detection models, such as You Only Look Once (YOLO) to track targets and objects in real-time across frames in a video sequence [19]. The DeepSort is used for multiple target tracking in videos. It combines two main components: a detection model (like YOLO, SSD, or Faster R-CNN) that identifies the targets in each frame from the video, and a tracking algorithm that maintains the identity of these objects across frames and follows closely the motion of the targets. Initially, the detection model identifies the class of the target and generates bounding boxes around these targets, providing also their corresponding positions and labels. Following, DeepSort extracts relevant features from the detected bounding boxes, which represent the visual characteristics and appearance of the targets. The numerical representation of these features is typically created by a neural network that performs the detection and tracking. Furthermore, using these extracted features, DeepSort associates objects detected in different frames. The DeepSort algorithm associates detections across frames. Matching detections and maintaining consistent identities through the consecutive frames is achieved by minimizing costs, such as the Hungarian algorithm. Also, DeepSort uses a prediction mechanism to maintain track of occluded or temporarily undetected objects until they reappear. As a result, temporary occlusions are less likely to occur. For each target identified in the video, DeepSort produces a continuous set of tracks related to their motion. In addition, the generated tracks contain the unique identity of targets across frames, allowing comprehensive analysis of object movement. In this research study, using Yolov7 as input, The DeepSORT algorithm perform tracking of different airborne targets. In situations with dynamic aerial movement and occlusions, DeepSort's capacity to associate and track objects across frames by utilizing appearance features and motion information is essential for preserving identities.

Therefore, in an anti-drone system, YOLOv7 operates as the initial detection module, processing input data to identify potential airborne targets. Detected objects, along with their bounding box coordinates and confidence scores, are then passed to DeepSort for tracking. DeepSort associates detections across frames, maintaining tracks for each identified target. The integrated system continuously analyzes the behavior of airborne targets, enabling real-time monitoring and threat assessment.

C. Experimental Setup

The experiments are conducted on a local machine using a NVIDIA Quadro P4000, an Intel(R) Xeon(R) W-2155@ 3.30GHz with 32GB of main memory, and Windows® as the operating system. As well as that, we have used Pytorch version 1.13.1 along with Cuda 11.6 and Cudnn v8.8 for running the Yolo model. Furthermore, selecting appropriate hyperparameters is crucial for the training and tuning of the developed model. Our process of tuning hyperparameters entails carefully adjusting their corresponding values to find optimal rates. Table I shows the hyperparameters used during training.

TABLE I. THE HYPERPARAMETERS USED

Hyperparameter	Value	Hyperparameter	Value
Epochs	150	Learning rate (lr)	0.01
Batch size	16	Weight decay	0.005
Image size	640×640	Momentum	0.937
Warmup epochs	3	Scale	0.5
Left and right flip	0.5	Translate	0.1

D. Evaluation Metrics

Evaluation metrics for our detection models include the following assessment metrics: Recall (R), Precision (P), Mean Average Precision (mAP), F1 score, and Frames Per Second (FPS). This allows a better evaluation of the developed models for multi-class detection since it utilizes verified and missed detection samples associated with the detection of each class target, such as False Positives (FP), False Negatives (FN), True Positives (TP) and True Negatives (TN). When it comes to P, the relevant detection results are considered, while recall is the total number of correct detections. Equations for determining these evaluation metrics are shown below:

$$R = \frac{\sum TP}{\sum TP + FN} \qquad (1)$$

$$P = \frac{\sum TP}{\sum TP + FP} \qquad (2)$$

For each category, the mean Average Precision represents the overall area under the precision-recall curve.

$$mAP = \frac{1}{N}\sum_{i=1}^{N} AP_n \qquad (3)$$

where, N is the number of target classes and AP_n is the mean mean average precision for each class.

$$FPS = \frac{\sum_{i=1}^{k} I}{Inferencetime} \qquad (4)$$

where, I is the total number of images used in the inference phase.

IV. RESULTS AND DISCUSSION

Using the tracking algorithm DeepSort and our detection model Yolov7, we present the results of the experiments conducted in this section. A detailed analysis of the quantitative metrics follows, providing insights into the strengths of the proposed approach.

A. Detection Performance

As first step, the detection model is run to recognize and identify the airborne targets efficiently and accurately. We have compared several single-shot object detector algorithms [20] to select the suitable model that satisfies the speed performance compromise required for anti-drone deployment. The efficacy of our developed model has been demonstrated in Table II, which details a selection of the experimental results of the most used models, based on detection performance confidence scores and inference speed. Therefore, it is shown that Yolov7 model surpasses the other models based on the provided results of detection metrics and inference speed. Also, the Yolov7 model reaches high accuracy and fast speed, comprises between speed performances. In addition, we have completed the model analysis by comparing the detection performance with respect to the precision and recall of each class in Table III. Indeed, it is shown that the model effectively detects the targets reaching high rates of the used evaluation metrics.

Fig. 1 shows the detection performance of the selected Yolov7 model as well as the generated loss and the behavior at each epoch during the training. The training and validation behaviors of the model are described in detail with respect to the aforementioned metrics; recall, precision, mAP@0.5 and mAP@0.5–0.95, as well as objects, classes and boxes losses. The curves converge to a fixed threshold after training for 150 epochs. Additionally, the model has demonstrated both optimal performance and high generalization ability without bias, variance, or overfitting or underfitting. Training and validation curves have similar behaviors with no gaps between them, and they converge at the same time (≈ 75 epochs). This model proves its effectiveness by continuously recording loss, precision, recall, and mAP metrics during training and validation processes.

As shown in Fig. 2 to Fig. 5, we have generated the evolution of the R, P and F1 curves with respect to the confidence score to provide deeper insight into the model. As can be seen from the curves, birds, drones, and airplane targets have similar and close detection behaviors, except for the building and dayframe classes. The precision, recall, and F1 curves show that the detection performances of all categories are above 90%. The precision-recall curve (see Fig. 3) shows that the model has a 96.8% mAP (area under the curve), which corresponds to a 96.8% precision-recall rate. Also, the precision-recall curve shows that the threshold performance metrics for bird is 0.997, drone 0.973, dayframe is 0.994, airplane 0.959 and building is 0.989. This percentage value also indicates whether the model is able to detect targets while guaranteeing a satisfactory recall and precision rate. As shown in F1-confidence curve (see Fig. 5), the confidence score is set at 0.467, which is important since starting from this point, the metrics are optimized and the performance balance is achieved. Additionally, the F1 curve shows the weighted harmonic of precision and recall, as well as the optimized confidence threshold of 0.467, which is highly required to perform an accurate, real-time detection. Other evaluation criteria such as confusion matrices, inference times, and real-time detection images have emphasized the model's performance. The confusion matrix of our model is shown in Fig. 6. There are five target classes with true positives located along the diagonal in dark blue. According to the true positive values, the proposed model is very effective and efficient at detecting and identifying the types of drones. To make the results more intuitive, we have integrated visualization about the detection performance of the model. Fig. 7 shows the detection of the airborne targets using unseen random images that confirm the model's ability to detect the aforementioned target classes.

TABLE II. EXPERIMENTAL RESULTS OF DETECTION MODELS

Model	Precision	Recall	mAP@0.5	mAP@0.5-0.95	Inference time (ms)
Yolov5	0.916	0.902	0.923	0.701	65.3
Yolov6	0.834	0.87	0.891	0.64	74
Yolov8	0.897	0.868	0.921	0.709	46
Yolov7-d6	0.957	0.928	0.966	0.712	38.5
Yolov7-w6	0.957	0.942	0.968	0.711	29.5
Yolov7	**0.973**	**0.957**	**0.982**	**0.753**	**27.5**

TABLE III. PERFORMANCE OF THE MODEL WITH RESPECT TO EACH TARGET CLASS

Target	Precision	Recall	mAP@0.5	mAP@0.5-0.95
all	0.973	0.957	0.982	0.753
Bird	0.997	0.997	0.997	0.85
Drone	0.956	0.958	0.973	0.549
Dayframe	0.995	0.966	0.994	0.79
Airplane	0.931	0.959	0.959	0.776
Building	0.989	0.912	0.989	0.798

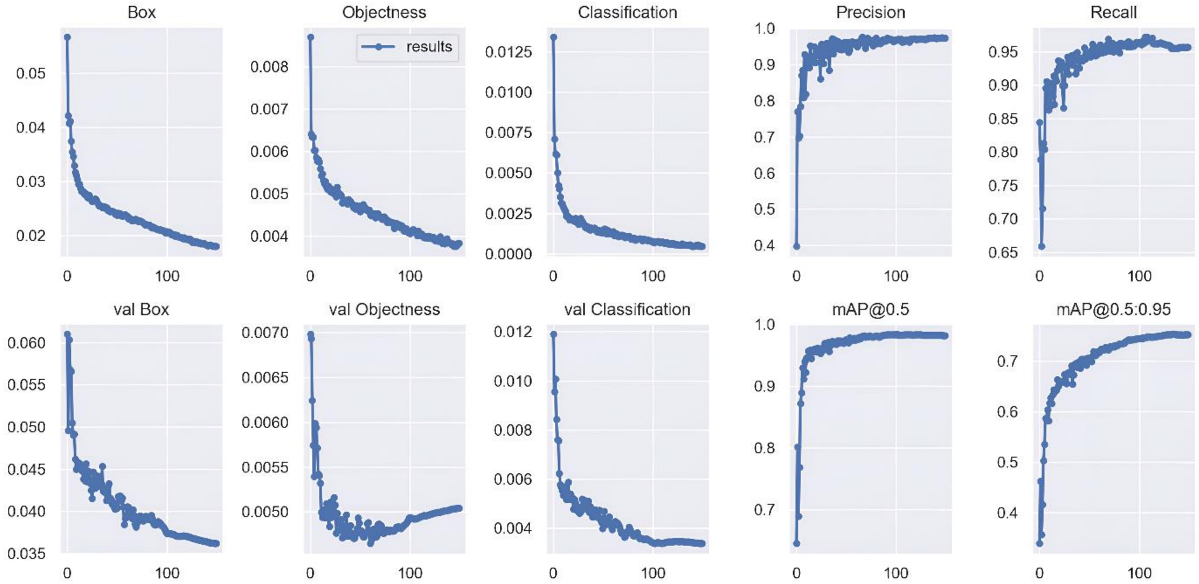

Fig. 1. Performance behavior of the improved model.

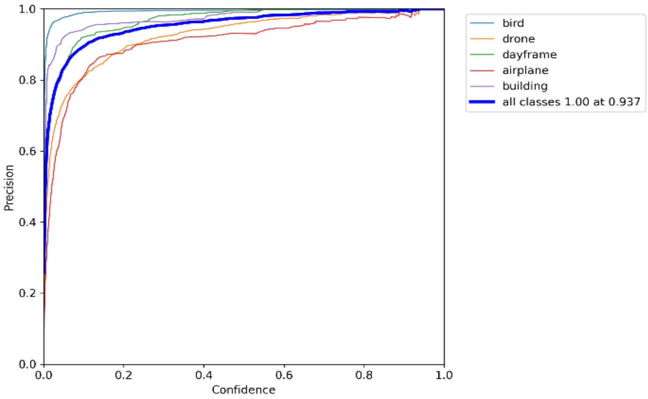

Fig. 2. Evolution of the performance of Yolov7 model with respect to Precision evolution curve over the target classes.

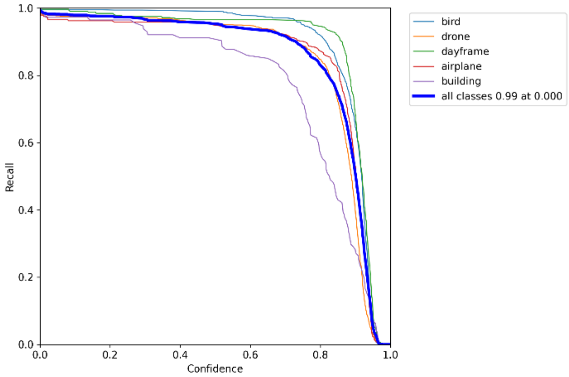

Fig. 3. Evolution of the performance of the Yolov7 model with respect to Precision- Recall evolution curve over the target classes.

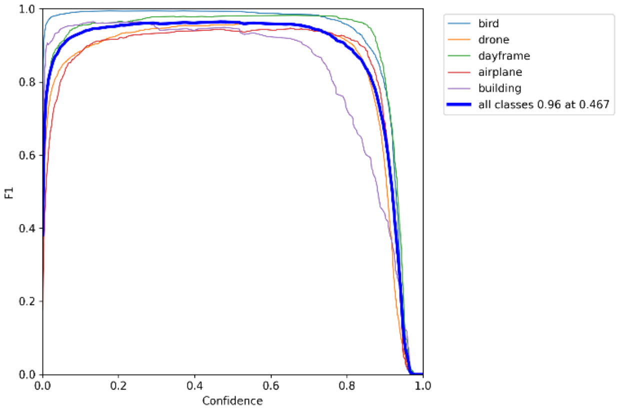

Fig. 4. Evolution of the performance of Yolov7 model with respect to Recall evolution curve over the target classes.

Furthermore, the developed model is capable of detecting the most encountered targets in real-time. The model has average inference of 27.5 ms, 1.1 ms for Non Max Supression (NMS) process and an ability to infer images in 0.002 seconds per image. Additionally, the FPS metric also determines the capacity of the model to process a set of images per second, which is dependent on the model's performance. Considering that the model is tested on 1179 images, it reaches a frame rate of 42, 8 FPS. This model represents the optimal performance speed compromise, as well as being qualitative and quantitative. Additionally, the model’s performance was evaluated using unseen images containing airborne targets that were barely visible to the human eye under complex conditions, mainly due to the altitudes and distances with respect to the observer.

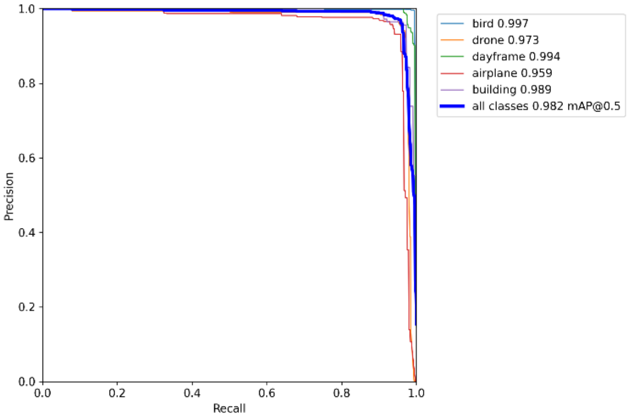

Fig. 5. Evolution of the performance of Yolov7 model with respect to F1 evolution curve over the target classes.

In view of the provided results, we confirm that our proposed model has the high inference time and the best precision, recall mAP@50 and mAP@50–95, thus outperforming the other models proposed in the literature.

Additionally, we have used performance and speed

Evaluation metrics that is suitable for our requirements and constraints to assess effectively the tested models during the development of our final Yolov7 model.

B. *DeepSort Tracking Results*

Using the selected model Yolov7, we have performed the tracking on different videos to assess the tracking ability. As part of the current study, Deepsort is used to track airborne targets for anti-drone deployment. It uses the patterns learned from the pre-trained Yolov7 detection model and later combines that with temporal information to predict associated targets' trajectories. The system keeps track of all objects by mapping their unique identifiers [21]. We have deployed the DeepSort on real-time videos that contain drones in different contexts, environments and times of the day to assess its ability to keep the target within the field of view. Fig. 8(a) and Fig. 8(b) represents a selection the tracking deployed on real-time video sequences. It is shown that model efficiently identifies and tracks the airborne targets, mainly drones and dayframes presents in the videos.

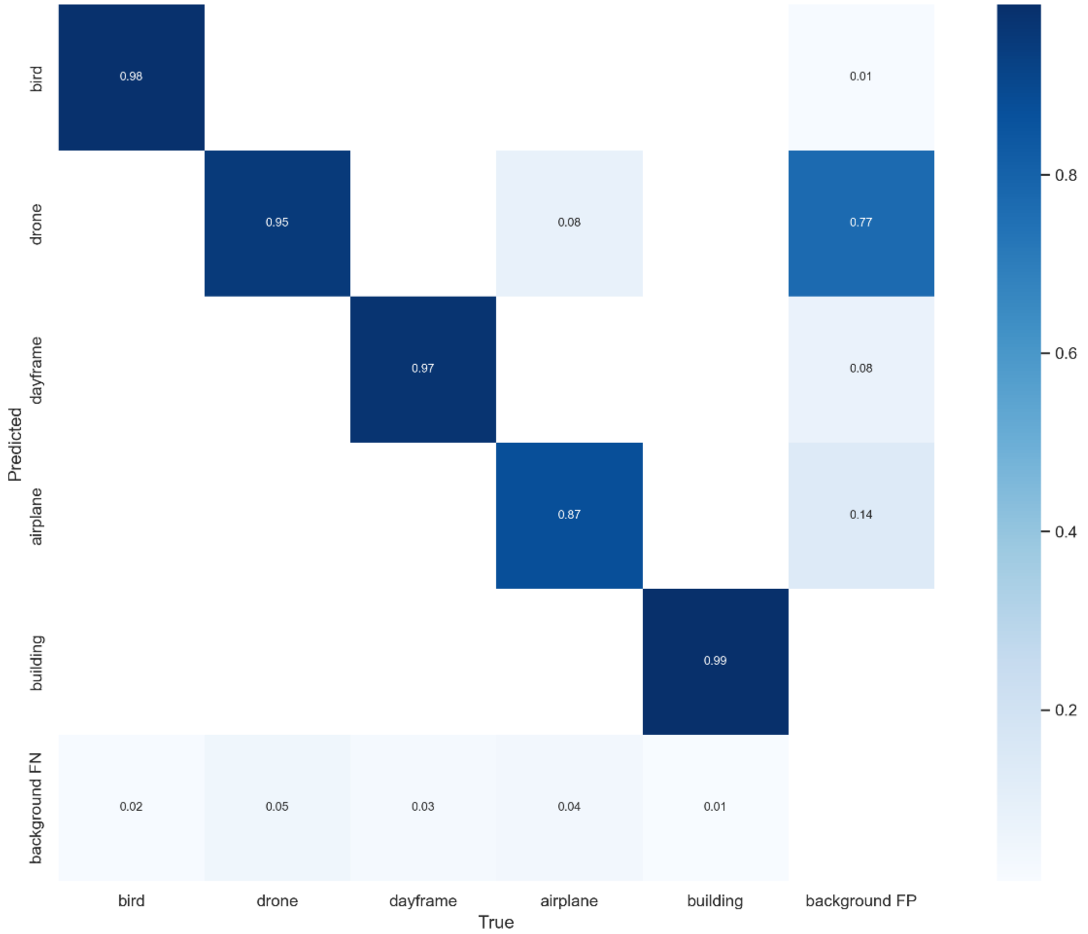

Fig. 6. Confusion matrix.

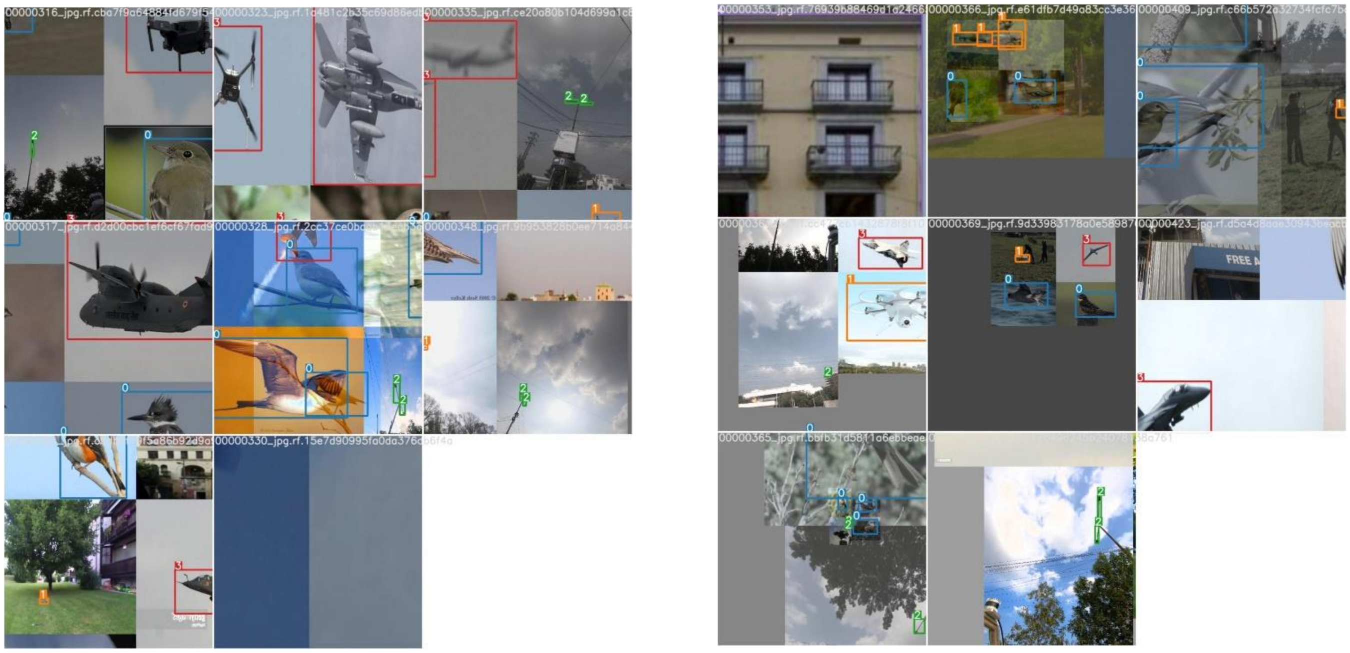

Fig. 7. Detection results of Yolov7 model.

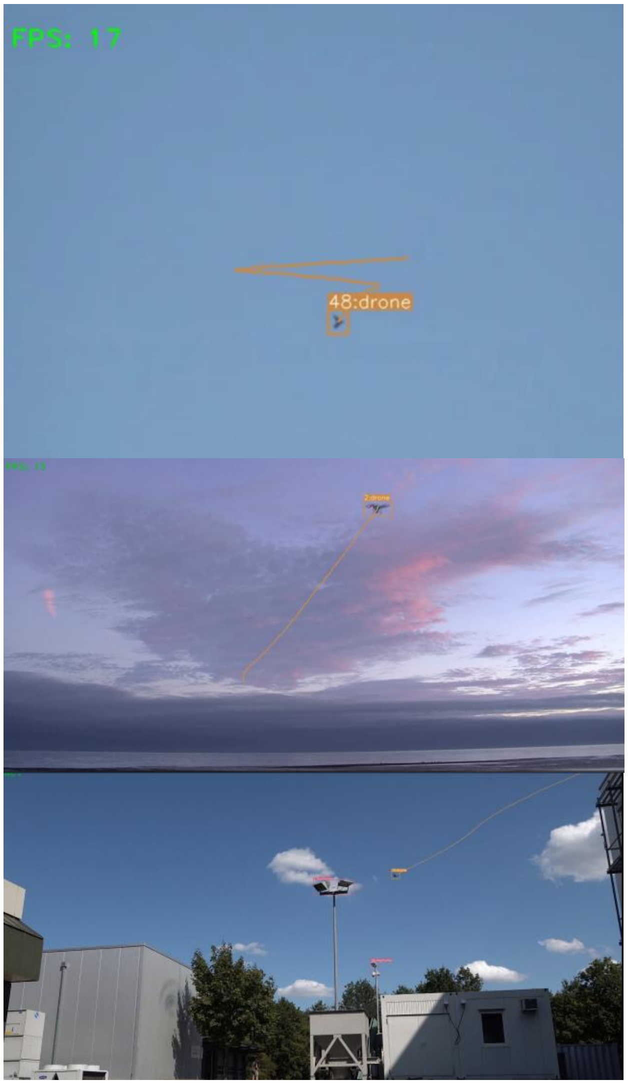
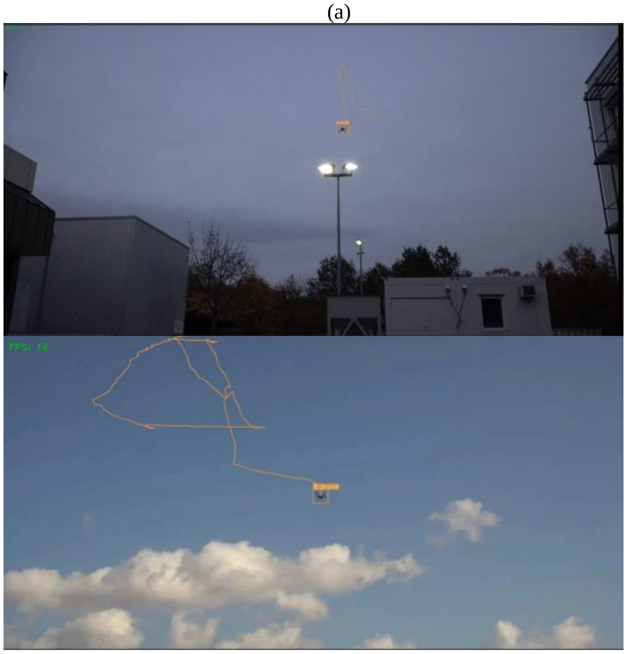
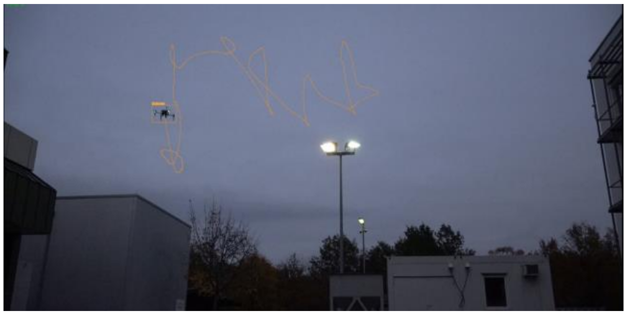


(a)





(b)

Fig. 8. (a) Captures from the tracking on different video sequences, (b) Captures from the tracking on different video sequences.

We demonstrate the efficacy of DeepSort in our experiments in tandem with the pre-trained YOLOv7 model for tracking the selected airborne targets. With robust tracking accuracy across diverse scenarios and ability to handle challenges such as target occlusions and rapid movements, the integrated system demonstrated the ability to perform effectively in challenging scenarios.

In comparison with the state-of-of the-art papers [8], [9], [10], [11], [12] , the proposed tracking approach outperforms the other proposed models based on the ability of our model to detect and identify five airborne targets using a varied and diversified dataset and also the high tracking performance to track the detected targets while generating bounding box around it and drawing its motion line across the successive frames. Further, the proposed model is able to detect, identify and track multi-airborne targets at different views, capture angles and environment which enhance significantly the overall performance. Therefore, the proposed DeepSort algorithm with Yolov7 provides the best compromise between the performance and speed and thus satisfying the anti-drone requirements and challenges.

V. Conclusion and Perspectives

Detecting and tracking airborne targets represent important task for the effectiveness of an anti-drone process. Our paper presents a real-time model for identifying and tracking common airborne targets. Based on experimental results, the models have 42.8 FPS detection speed, 0.957 recall, 0.973 precision, 0.732, 0.982 map@0.50–0.95 and 0.753 map@0.50–0.95. In comparison with various benchmark instances recently published in the literature, the proposed model provides a high detection rate and fast inference times. Therefore, the combination of DeepSort algorithm and Yolov7 model provides high detection and tracking performance tested on real-time videos. The conducted experiments showed satisfactory results since the targets are detected and tracked rapidly and effectively across the successive frames of the videos. It suggests potential enhancements and future research directions to improve the algorithm's efficacy. In future work, we are going to collect a larger video dataset including also airplanes, and birds in the same sequences to improve further the tracking process.

Towards High Quality PCB Defect Detection Leveraging State-of-the-Art Hybrid Models

Tuan Anh Nguyen, Hoanh Nguyen*
Faculty of Electrical Engineering Technology, Industrial University of Ho Chi Minh City, Ho Chi Minh City, Vietnam

***Abstract*—The automatic detection of defects in printed circuit boards (PCBs) is a critical step in ensuring the reliability of electronic devices. This paper introduces a novel approach for PCB defect detection. It incorporates a state-of-the-art hybrid architecture that leverages both convolutional neural networks (CNNs) and transformer-based models. Our model comprises three main components: a Backbone for feature extraction, a Neck for feature map refinement, and a Head for defect prediction. The Backbone utilizes ResNet and Bottleneck Transformer blocks, which are proficient at highlighting small defect features and overcoming the shortcomings of previous models. The Neck module, designed with Ghost Convolution, refines feature maps. It reduces computational demands while preserving the quality of feature representation. This module also facilitates the integration of multi-scale features, essential for accurately detecting a wide range of defect sizes. The Head employs a Fully Convolutional One-stage detection approach, allowing for the prediction process to proceed without reliance on predefined anchors. Within the Head, we incorporate the Wise-IoU loss to refine bounding box regression. This optimizes the model's focus on high-overlap regions and mitigates the influence of outlier samples. Comprehensive experiments on standard PCB datasets validate the effectiveness of our proposed method. The results show significant improvements over existing techniques, particularly in the detection of small and subtle defects.**

Keywords—PCB defect detection; hybrid neural network; bottleneck transformer; ghost convolution; wise-IoU loss

I. INTRODUCTION

PCBs are the cornerstone of modern electronics, providing a critical framework for the interconnection of electronic components. They consist of a complex network of conductive pathways, tracks, and traces etched onto a non-conductive substrate, enabling the integration of various components such as resistors, capacitors, and integrated circuits to form functional electronic devices. The integrity of these boards is paramount, as any defects can lead to malfunctioning or failure of the electronic equipment. PCB defect detection, therefore, is a vital process in the manufacturing industry, aimed at identifying and rectifying flaws such as short circuits, open circuits, missing components, or misalignments. Traditionally performed by human inspectors, this process has increasingly been entrusted to automated systems that leverage advanced imaging technologies and machine learning algorithms. These systems offer greater accuracy, consistency, and efficiency in detecting a wide array of subtle and overt flaws that might be overlooked by the human eye, ensuring high-quality outputs in the fast-paced production environments that define today's electronic manufacturing sector.

Traditional image processing techniques for PCB defect detection typically involve a sequence of algorithmic steps such as noise reduction, thresholding, edge detection, and pattern recognition to analyze images of PCBs for anomalies. These methods often start with pre-processing to enhance image quality, followed by segmentation to isolate regions of interest. Techniques like morphological operations may be used to highlight features of defects, and template matching could be employed to compare segments against known good patterns. While these techniques are deterministic and relatively straightforward to implement, they come with significant shortcomings. They tend to be highly sensitive to variations in lighting, alignment, and image quality, leading to false positives or negatives. Additionally, traditional methods may struggle with the complexity of modern PCBs, which can have intricate designs and high component densities. These methods can also be computationally intensive and inflexible, requiring manual tuning and adjustments when dealing with different types of PCBs or new defect profiles, limiting their scalability and adaptability in fast-evolving manufacturing environments.

In recent years, deep learning has revolutionized the field of artificial intelligence, leading to significant advancements in various domains such as computer vision, natural language processing, autonomous vehicles, and medical diagnostics [1, 2]. At its core, deep learning utilizes neural networks with multiple layers to learn representations of data with multiple levels of abstraction, enabling the discovery of intricate structures in large datasets. As a result, applications that were once thought to be challenging, like image and speech recognition, have seen substantial improvements in accuracy and efficiency. Leveraging these developments, deep learning has also been proposed for PCB defect detection, representing a paradigm shift from traditional image processing techniques. Unlike conventional methods, which rely on hand-engineered features and are prone to performance degradation under variations in lighting and complex patterns, deep learning models can automatically learn to identify defects from data. These models, particularly convolutional neural networks (CNNs), have shown remarkable success in detecting intricate and subtle anomalies on PCBs by learning features directly from the raw pixels. However, despite their success, current deep learning methods for PCB defect detection still face challenges. They require large annotated datasets to learn effectively, which can be expensive and time-consuming to create. Moreover, they may not generalize well across different

PCB designs or manufacturing processes without extensive retraining or fine-tuning. To address these shortcomings, the method proposed in this paper integrates advanced neural network architectures that enhance feature extraction and defect localization capabilities, while also employing data augmentation and specialized loss functions to improve model robustness and generalizability. This approach aims to overcome the limitations of both traditional image processing and current deep learning techniques, providing a more reliable and adaptable solution for PCB defect detection.

The rest of the paper is organized as follows: Section II presents related studies; Section III details the proposed model; Section IV describes the experiments and results; Section V provides the conclusions.

II. Related Work

The emergence of end-to-end deep learning technology [3, 4] has introduced new opportunities for PCB fault detection. Currently, extensive research is being carried out on PCB defect detection methods that leverage deep learning. Mingu et al. [5] presented a novel contactless inspection method that utilizes deep learning to analyze thermal images for the detection of PCBA defects. The authors explore the efficacy of combining a rule-based object detection approach, employing a structural similarity index map, with advanced deep learning techniques including CNNs, region with CNN features, and autoencoders, thereby enhancing the accuracy and reliability of contactless PCBA inspection methods. Sik-Ho et al. [6] introduced PCBMTL, multitask learning model designed to concurrently tackle classification and segmentation tasks, specifically tailored for scenarios with limited data availability. This model leverages the intrinsic correlation between segmentation knowledge and classification tasks, significantly enhancing the classification accuracy even when only a sparse dataset is available. Gor et al. [7] proposed an Automated Visual Inspection (AVI) methodology for detecting hardware trojans (HTs) on PCBs, utilizing imagery from a low-cost digital optical camera. This method combines traditional computer vision techniques with a dual-tower Siamese Neural Network (SNN), structured within a three-stage pipeline for effective HT detection. To address the issues of inadequate accuracy and speed in visual matching systems, the study in [8] introduced a deep learning-based alignment system utilizing YOLOv5. This system enhances production efficiency by preprocessing images captured by an industrial camera, delineating sensitive areas rich in feature points for improved alignment accuracy. Naifu et al. [9] employed techniques such as relative position estimation, spatially adjacent similarity, and k-means clustering of patches to discern finely classified semantic features, followed by a local image patch completion network that learns the feature consistency between these local patches and the background, using the disparities between the estimated and original image patches to effectively identify anomaly areas in PCBs.

To enhance the efficiency of current defect detection algorithms, [10] introduced RAR-SSD, a novel method combining multiscale PCB defect target detection with an attention mechanism. This approach integrates a lightweight receptive field block module (RFB-s) with an attention mechanism, effectively focusing on crucial features across various channels without escalating computational demands, and incorporates a feature fusion module that synergizes low-level and high-level feature information, resulting in a comprehensive feature map that significantly boosts fault recognition accuracy. JiaYou et al. [11] introduce an advanced deep learning network specifically designed to tackle the challenge of detecting small or variable defects on PCBs in real-time. The proposed improvements include a unique multi-scale feature pyramid network that boosts tiny defect detection by incorporating context information and a refined complete intersection over union loss function that accurately targets and identifies these minuscule defects. CS-ResNet [12] introduced a new model, which innovates upon the standard ResNet by incorporating a cost-sensitive adjustment layer. This model specifically addresses class imbalance by assigning greater weights to minority real defects based on their degree of imbalance, and optimizes performance through the minimization of a weighted cross-entropy loss function. Boyuan et al. [13] presented a cutting-edge PCB defect detection method utilizing YOLOv7. Additionally, the integration of the CBAM attention mechanism with a feature fusion module enables the model to selectively focus on pertinent feature channels and spatial locations, significantly boosting the discriminative power of the feature representation and thereby increasing overall accuracy. KD-LightNet [14] introduced an efficient and lightweight defect detection network optimized for edge computing scenarios. The network architecture, LightNet, is crafted using structure reparameterization to boost feature extraction capabilities while reducing model complexity.

III. Method

In this section, we provide details of our approach for PCB defect detection. Fig. 1 illustrates the overall structure of the proposed model, which includes three modules: Backbone for extracting features from the input image, Neck for enhancing the feature maps, and Head for making predictions. Initially, the input image is processed by the Backbone, consisting of multiple layers that perform feature extraction. Subsequently, the extracted features are refined by the Neck module, which is designed to enhance and integrate the feature maps at different scales. Finally, the Head module takes over, comprising three key components: Classification, Center-ness, and Regression, which work collectively to output the final defect detection results. Details of each module will be explained in the following subsections.

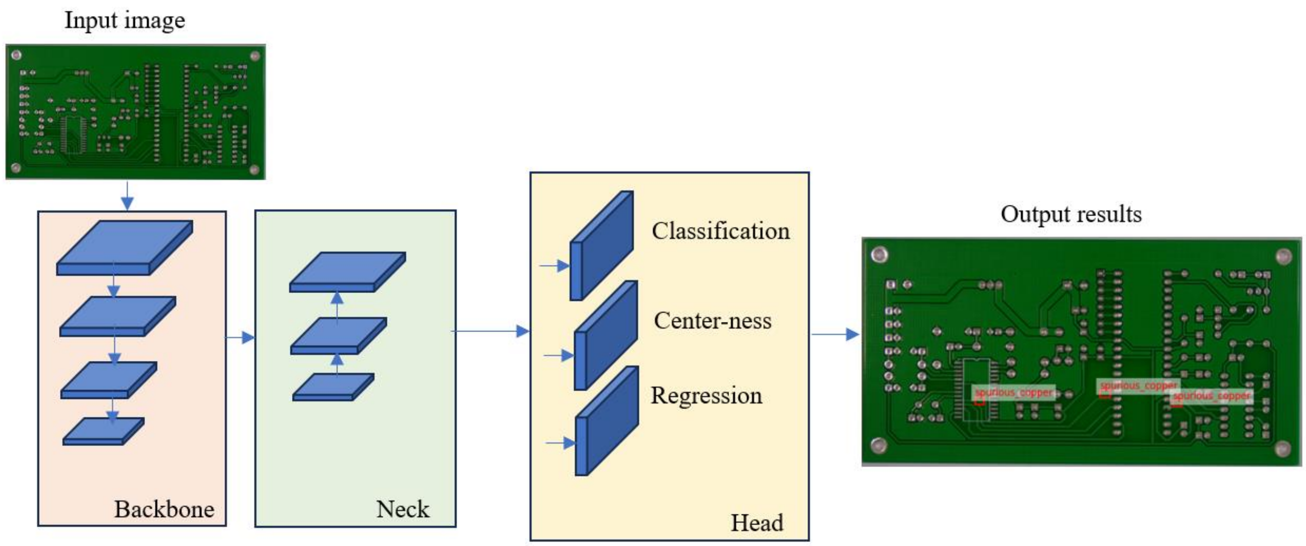

Fig. 1. Overall structure of the proposed model.

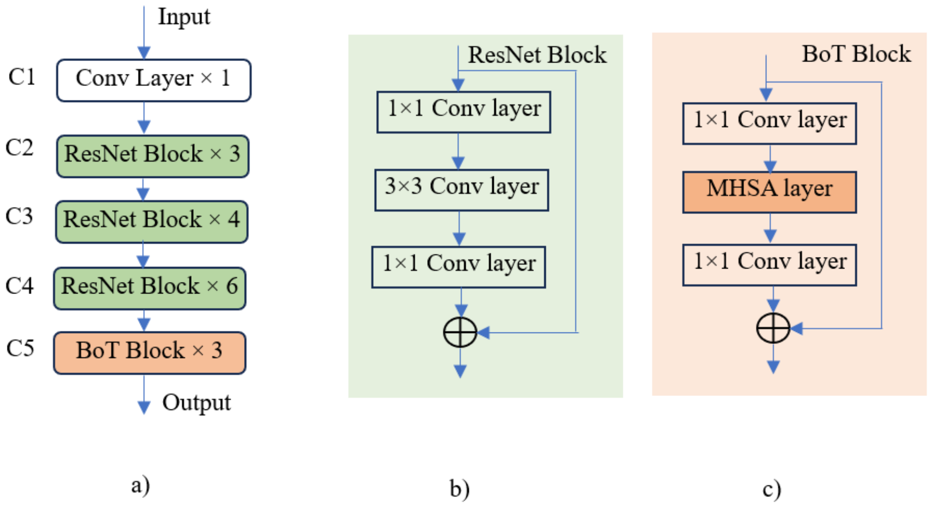

Fig. 2. The structure of the feature extraction network (a) which includes input (b) ResNet Block (c) BoT block.

A. *Feature Extraction with Self-Attention Mechanism*

1) The backbone network proposed for PCB defect detection is a critical component of the object detection system, designed to process input images and extract relevant features that are essential for identifying defects. The advanced architecture of this backbone is built upon a combination of convolutional layers and ResNet blocks [15], further enhanced with Bottleneck Transformer (BoT) blocks [16]. The structure is outlined in Fig. 2, which depicts the sequential layers and blocks within the network. In detail, the backbone begins with a single convolutional layer (C1) that performs initial feature extraction. This is followed by a series of ResNet blocks (C2, C3, C4) that apply residual learning to prevent the vanishing gradient problem and allow deeper networks to learn effectively. Each ResNet block consists of a bottleneck design with three convolutional layers: a 1×1 convolution that reduces the dimensionality, a 3×3 convolution that processes features, and another 1×1 convolution that restores dimensionality. These blocks are equipped with skip connections that add the input of the block to its output, facilitating the training of deep networks by allowing gradients to flow through.

2) The novelty of this architecture lies in the integration of BoT blocks (C5), which introduce a multi-head self-attention (MHSA) mechanism within the transformer architecture [17]. Each BoT block is comprised of a 1×1 convolution layer followed by an MHSA layer and another 1×1 convolution layer. The MHSA layer enables the network to focus on different parts of the image when extracting features, which is particularly beneficial for detecting small objects-a common challenge in PCB defect detection. This capability is contrasted with the DETR (Detection Transformer) model [3], which shows improvements in detecting larger objects but not smaller ones. The use of BoT blocks in the backbone could potentially address this shortfall, enhancing the model's ability to recognize smaller defects on PCBs that are often difficult to detect. In the BoT block, the MHSA mechanism efficiently captures long-range dependencies across the input feature map. By utilizing multiple attention heads, MHSA is able to concurrently process and focus on various aspects of the semantic space within the feature map. This allows the model to consider information from different representation subspaces at reduced computational costs. The operation of MHSA is as follows:

$$MHSA(Q,K,V) = Concatenation(H^0,H^1,H^2,H^3) \quad (1)$$

where, Q, K, and V represent three linear layers used for computing queries, keys, and values in a standard self-attention task. H^i represent the head of the self-attention mechanism as follows:

$$H^i = Softmax(Q_iK_i^T + qr^T) \times V_i, i \in [0,3] \quad (2)$$

$$qr = (R_h + R_w) \times Q \quad (3)$$

where, R_h ans R_w represent height and width relative position, respectively.

B. Improving Multi-scale Feature with Ghost Convolution

The neck network for PCB defect detection is designed based on Ghost Convolution [18], as depicted in Fig. 3. This network serves as an intermediary between the feature-rich output from the backbone and the predictive head of the model, enhancing the feature maps for more accurate defect localization. Starting from the deepest layer (C5), the network utilizes Ghost Convolution layers, which are designed to generate more feature maps from fewer intrinsic maps, thereby reducing computational requirements while maintaining effective representation capacity. This is followed by an upsampling step, which increases the resolution of the feature maps to match the scale of the subsequent layer. The upscaled features are then concatenated with the features from the previous layer (C4), integrating multi-level semantic information. This process is repeated as the network proceeds to shallower layers (C4 to C3). Each time, the Ghost Convolution layers generate rich feature representations that are then upsampled and concatenated with features from earlier in the network. This concatenation ensures that the final feature maps encompass both high-level semantic information and finer, low-level details, which is crucial for detecting the often-minute anomalies present in PCBs. The repeated pattern of Ghost Convolution, upsampling, and concatenation progressively enriches the feature maps, culminating in a comprehensive composite that feeds into the detection head. The head then uses these refined features to make precise predictions about the presence, location, and types of defects on the PCB. This neck architecture, with its efficient and hierarchical processing, is particularly well-suited for the demands of PCB defect detection, where the ability to discern subtle and small-scale imperfections is key.

1) Ghost convolution: Ghost Convolution is an innovative approach to convolutional neural network design that aims to reduce computational workload and model complexity without sacrificing performance. The core idea behind Ghost Convolution is to generate additional feature maps, known as "ghost" features, from inexpensive operations on the original convolutional features. This is achieved by applying a series of linear transformations, such as simple arithmetic operations or small-kernel convolutions, to the output of standard convolutional layers. The original set of feature maps is obtained through regular convolution operations, which can be computationally intensive. Then, for each of these original maps, several ghost feature maps are derived using the lightweight transformations. These ghost maps are capable of capturing variations and fine details by reusing the information present in the original feature maps, effectively augmenting the feature space with minimal extra computation. This process substantially reduces the number of direct convolutions that the network needs to perform, thus decreasing the number of parameters and the computational cost. Despite this reduction, Ghost Convolution preserves the network's capacity to encode rich and complex representations of the input data, making it particularly useful for resource-constrained environments or applications where efficiency is paramount, such as mobile devices, embedded systems, or real-time applications.

For a standard convolution, the number of FLOPs is calculated as follows:

$$\text{FLOPs}_{Standard} = H_{out} \times W_{out} \times N_{out} \times (C_{in} \times K_h \times K_w + 1) \quad (4)$$

where, H_{out} and W_{out} are the height and width of the output feature map; N_{out} is the number of output channels; C_{in} is the number of input channels; K_h and K_w are the height and width of the kernel.

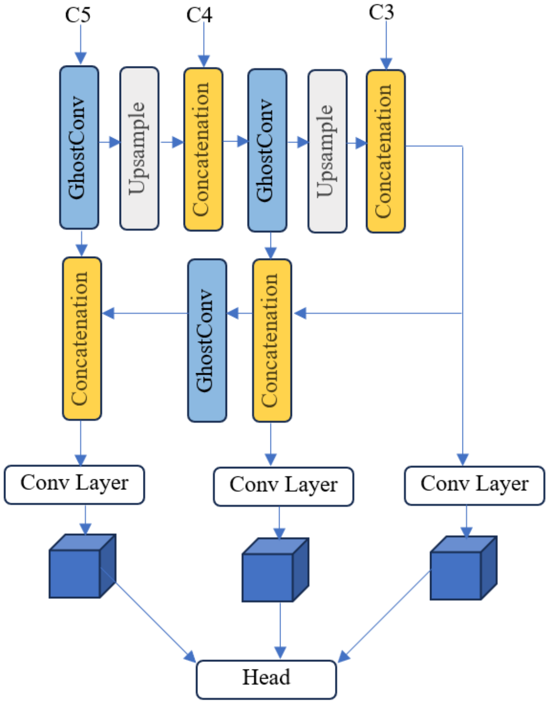

Fig. 3. The neck network with ghost convolution layers.

For Ghost convolution, we first calculate the FLOPs for the initial standard convolution that generates the intrinsic feature maps, and then add the FLOPs for the linear operations used to generate the ghost feature maps. The equation for Ghost convolution is:

$$\text{FLOPs}_{Ghost} = H_{out} \times W_{out} \times N_{int} \times (C_{in} \times K_h \times K_w + 1) + H_{out} \times W_{out} \times N_{ghost} \times \left(N_{int} \times K_{hghost} \times K_{wghost} + 1\right) \tag{5}$$

where, N_{int} is the number of intrinsic output channels produced by the initial standard convolution; N_{ghost} is the number of ghost channels generated per intrinsic channel; K_{hghost} and K_{wghost} are the height and width of the kernel for generating the ghost feature maps, which are typically much smaller than the original convolution kernel size.

The term $N_{int} \times (C_{in} \times K_h \times K_w + 1)$ calculates the FLOPs for the initial convolution, and the term $N_{ghost} \times \left(N_{int} \times K_{hghost} \times K_{wghost} + 1\right)$ calculates the FLOPs for generating the ghost feature maps. Typically, N_{int} is much less than N_{out} and the kernel size for ghost operations (K_{hghost}, K_{wghost}) is smaller, leading to a significant reduction in FLOPs compared to standard convolution.

C. Detection Head with Wise-IoU Loss

1) We employ FCOS head [19] on each output feature layer. FCOS divides its detection head into three branches: the classification branch, the bounding box regression branch, and the centerness branch. In classification branch, a Focal Loss [20] is used to address class imbalance by reducing the weight of easy negatives. The centerness branch uses a binary cross-entropy loss that guides the model to predict higher centerness values for locations closer to the center of an object. For the bounding box regression branch, Wise-IoU loss [21] is employed. This is a novel loss function that modulates the geometric penalty based on the overlap between the predicted bounding box and the ground truth. If the overlap is high, the penalty is reduced, which helps the model to better refine boxes that are already largely accurate. The Wise-IoU loss also includes an outlier penalty term that increases the loss for poor predictions, preventing the model from being overly influenced by difficult or mislabeled examples. The formula for the Wise-IoU loss function is shown as follows:

$$L_{Wise-IoU} = r \times L_{IoU} \times exp(\frac{\left(x-x_{gt}\right)^2 + (y-y_{gt})^2}{(W_g^2 + H_g^2)}) \tag{6}$$

where, r represents the gradient gain.

2) The Wise-IoU loss specifically enhances the bounding box regression branch by incorporating a distance attention mechanism that scales the loss based on the distance metric between the anchor and the target frame. This scaling ensures that when the predicted box is already close to the ground truth (high IoU), the model is encouraged to make finer adjustments rather than over-penalizing small discrepancies. Moreover, by introducing a gradient attenuation factor for outliers, the Wise-IoU loss ensures that samples with poor quality predictions do not dominate the gradient update during backpropagation, thus stabilizing training and steering the model away from local optima that are not generalizable. This thoughtful design of the loss function supports more precise localization in PCB defect detection, which is critical for ensuring the accurate identification of defects.

IV. Experiments

A. Dataset and Experimental Setup

The dataset utilized in this study is derived from the PCB defect dataset released by the Intelligent Robotics Open Laboratory at Peking University. It encompasses various types of defects, such as shorts, open circuits, spurs, spurious copper, mouse bites, and missing holes. To mitigate the risk of network overfitting, we augmented the original 693 samples using techniques like random rotations, random cropping, brightness adjustments, and noise injection, resulting in a substantial increase to 5,814 samples. The distribution of different defect types is depicted in Fig. 4. We partitioned the expanded dataset into training, validation, and test sets in a ratio of 6:2:2, respectively.

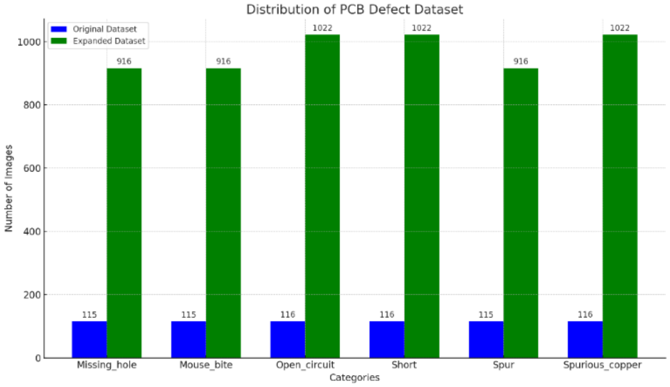

Fig. 4. Distribution of PCB defect dataset.

We conducted our training and evaluation on a high-performance Windows PC outfitted with an Intel Core i7-10400 CPU, an NVIDIA GeForce RTX 4080 GPU, and 32GB of RAM, ensuring efficient processing capabilities for deep learning tasks. Our software stack consisted of Python 3.8, leveraging libraries such as OpenCV for image processing and PyTorch for model development and training. The models were trained over 300 epochs with a batch size of 2, and we standardized the input image size to 640×640 pixels to maintain consistency in training and testing.

For model evaluation, we adopted two primary metrics: the mean average precision (mAP) and the detection speed, measured in frames per second (FPS). The mAP provides a comprehensive measure of model accuracy across all classes, factoring in both precision and recall, while FPS gauges the model's real-time performance capabilities. These benchmarks allowed us to assess the overall effectiveness and efficiency of our PCB defect detection models in a controlled and quantifiable manner.

B. Comparison with other Models

Table I provides a comparative analysis of various object detection models on the PCB defect dataset, showcasing their performance in terms of mean average precision (mAP), frames per second (FPS), and computational complexity measured in GFLOPs. The proposed model outperforms all other models with an exceptional mAP of 99.2%, indicating its superior accuracy in defect detection. Despite this high precision, it maintains a competitive detection speed of 51 FPS, balancing efficiency with effectiveness. Notably, the proposed model achieves this while having a lower computational cost (41.0 GFLOPs) than YOLOv5 and Faster R-CNN, which have higher GFLOPs of 100 and 170, respectively. The YOLOv7 and the Improved YOLOv5 models also exhibit high mAP scores, suggesting that the latest iterations and enhancements in the YOLO series continue to advance the state-of-the-art in object detection. However, the proposed model's edge in mAP suggests that the integration of novel architectural features or training strategies could be particularly beneficial for the specific challenges presented by PCB defect detection. The Transformer-YOLO and the Improved YOLOv5, while yielding high accuracy, do not report FPS, which leaves a gap in understanding their real-time applicability. On the other end of the spectrum, SSD demonstrates the lowest GFLOPs, indicating a very efficient model, but it lags in mAP, underscoring a trade-off between computational efficiency and detection accuracy. Overall, the results in Table I highlight the proposed model's capability to set a new benchmark for PCB defect detection by achieving a harmonious balance between accuracy, speed, and computational efficiency.

Fig. 5 presents a comprehensive visualization of the detection results achieved by the proposed PCB defect detection model. Across multiple instances, the model successfully identifies and localizes various types of PCB defects. Each type of defect is accurately marked with bounding boxes and labeled, indicating a high level of precision in the model's predictive capability. The clarity of the bounding boxes and the accuracy of the labels suggest that the model is well-tuned to the intricacies of PCB defect detection. The absence of mislabeling or missed detections in the provided visualization underscores the robustness of the model and its potential for practical applications in quality control and automated inspection systems within electronic manufacturing.

TABLE I. COMPARING THE PROPOSED MODEL WITH OTHER MODELS ON THE PCB DEFECT DATASET

Models	mAP (%)	FPS	GFLOPs
Faster R-CNN [22]	74.4	21	170
SSD [23]	82.2	42	2.5
YOLOv3 [24]	87.2	69	65
YOLOv5	91.4	102	100
Transformer-YOLO [25]	97.0	-	-
YOLOv7 [26]	97.8	54	51.2
Improved YOLOv5 [27]	97.9	-	53.5
Proposed Model	99.2	51	41.0

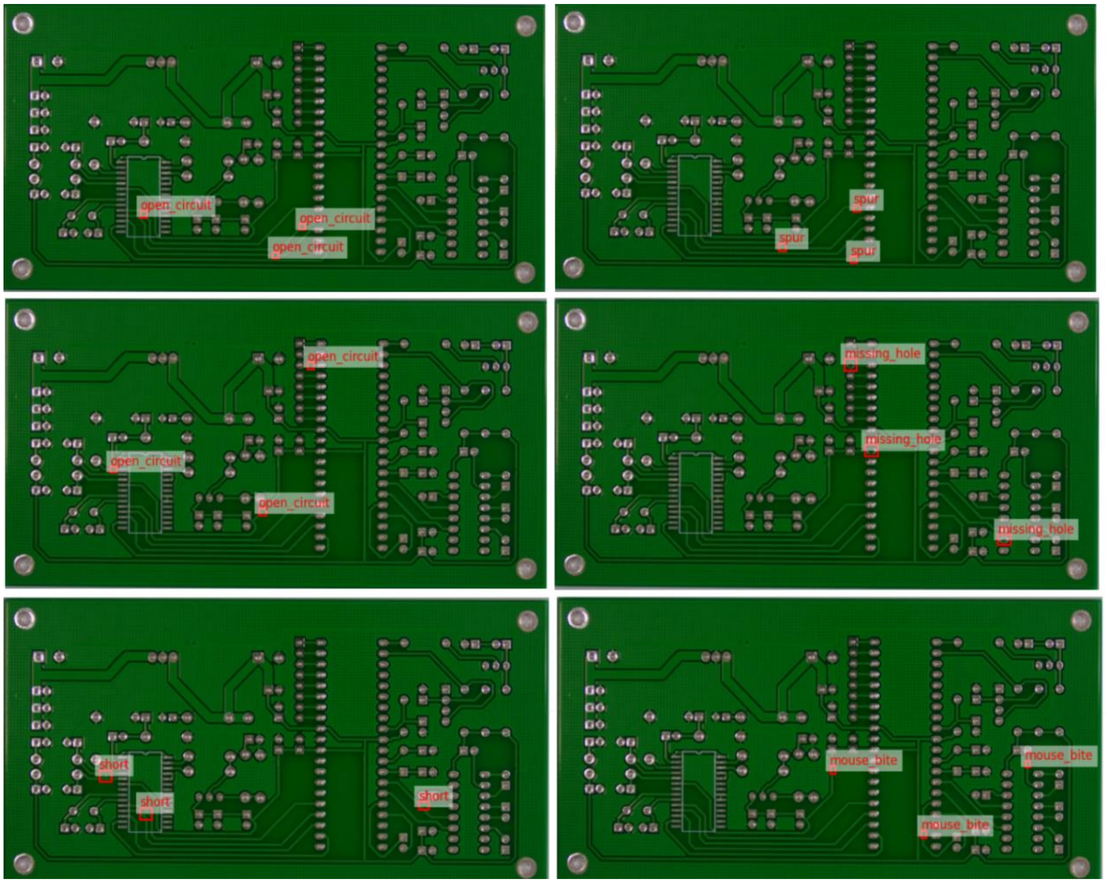

Fig. 5. Visualization of detection results of the proposed model.

C. Effect of Backbone with Self-Attention Mechanism

We also conduct experiments on the PCB defect validation set with various backbone architectures to evaluate the effectiveness of the proposed backbone with self-attention mechanism. Fig. 6 illustrates the performance trade-offs between mean average precision (mAP) and inference speed (FPS) for various backbone architectures on the validation set, including ResNet-50, ResNet-101 [15], EfficientNet [28], SENet-50 [29]. The proposed model achieves the highest mAP of 98.4% with a competitive FPS of 51, showcasing its superior defect detection accuracy without significantly compromising on speed. The ResNet-50 and ResNet-101 architectures offer a good balance between accuracy and speed, with ResNet-101 slightly trailing in FPS at 41 but offering near-top mAP performance at 98.2%. Notably, EfficientNet stands out with the highest FPS of 68, suggesting it is the fastest model; however, this speed comes at the cost of a lower mAP of 95.8%. SENet-50 has the lowest mAP of 94.4% and a modest FPS of 48, indicating it may not be the optimal choice for scenarios where high precision is critical. Overall, the proposed model’s impressive mAP, coupled with a substantial FPS, positions it as a compelling choice for real-time PCB defect detection applications.

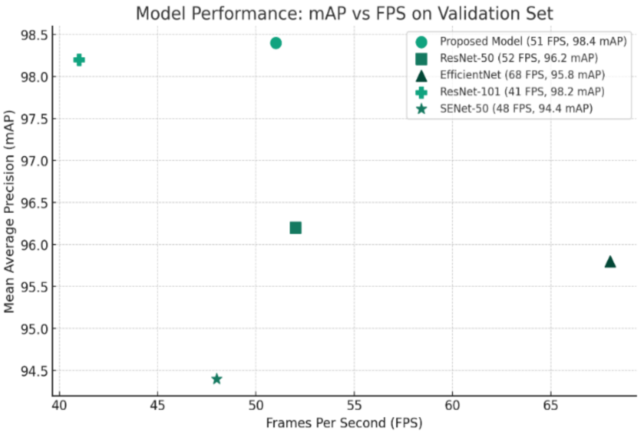

Fig. 6. The performance trade-offs between mean average precision (mAP) and inference speed (FPS) for various backbone architectures on the validation set.

V. Conclusions

In conclusion, this research paper proposes a novel approach to PCB defect detection, leveraging advanced hybrid neural network architecture. Our model integrates a ResNet and Bottleneck Transformer Backbone, a Ghost Convolution Neck, and Fully Convolutional One-stage detection Head, showing superior performance in identifying subtle and small-scale defects on PCBs. The comparative analysis highlights our model's exceptional mean average precision of 99.2%, significantly surpassing that of existing object detection models. Moreover, it achieves this high level of accuracy while maintaining a competitive detection speed of 51 FPS and requiring fewer computational resources compared to other high-performing models. The introduction of extensive augmentation techniques has further enhanced the dataset's diversity, improving the model's robustness and its ability to generalize across various PCB defect types. Future work will focus on optimizing the model to further improve its detection capabilities, particularly for the smallest and most challenging defects. Additionally, we will explore the potential for real-time processing in greater depth, aiming to extend the model's applicability to industrial settings and automated quality control systems. The success of this study marks a significant step forward in the field of automated defect detection, promising to enhance the reliability and efficiency of electronic manufacturing processes through the adoption of advanced neural network architectures.

Advancing Parkinson's Disease Severity Prediction using Multimodal Convolutional Recursive Deep Belief Networks

Shaikh Abdul Hannan
Assistant Professor, Department of Computer Science and Information Technology,
Al-Baha University, Al-Baha, Kingdom of Saudi Arabia

***Abstract*—Parkinson's disease (PD), a progressive neurological ailment predominantly affecting individuals over the age of 60, involves the gradual loss of dopamine-producing neurons. The challenges associated with the subjectivity, resource intensity, and limited efficacy of current diagnostic methods, including the Unified Parkinson's Disease Rating Scale (UPDRS), neuroimaging, and genetic analysis, underscore the need for innovative approaches. This paper introduces a groundbreaking multimodal deep learning framework that integrates Recurrent Neural Networks (RNN-DBN) for precise feature selection and Convolutional Neural Networks (CNNs) for robust feature extraction, aiming to enhance the accuracy of PD severity prediction. The methodology synergistically incorporates genetic data, imaging data from MRI and PET scans, and clinical evaluations. CNNs effectively capture spatial and temporal patterns within each data modality, preserving inter-modal linkages. The proposed RNN-DBN architecture, by skillfully leveraging temporal dependencies, improves model interpretability and provides a clearer understanding of the progression of Parkinson's disease symptoms. Evaluation across diverse PD datasets demonstrates superior predictive performance compared to existing methods. This multimodal deep learning framework holds the potential to revolutionize PD diagnosis and monitoring, offering physicians a valuable tool for assessing the condition's severity. The integration of various data sources enhances the model's accuracy, providing a holistic perspective on Parkinson's disease progression. This, in turn, facilitates improved clinical decision-making and patient care. Notably, the implementation in Python achieves a remarkable accuracy of 94.87%, surpassing existing methods like EOFSC and CNN by 1.44%.**

Keywords*—Parkinson's Disease (PD); Convolutional Neural Networks (CNN); Deep Belief Networks (DBN); Rat Swarm Optimization (RSO)

I. Introduction

Parkinson's disorder is a persistent, innovative neurodegenerative condition marked by a gradual degeneration of dopamine-producing brain cells. This causes both non-motor symptoms like mental deterioration and anxiety and depression in addition to physical signs like shaking hands, a slowing of activity, and stiffness [1]. Although the precise etiology is yet unresolved, environmental and genetic variables are thought to be involved [2]. Although there doesn't exist a therapy, there are treatments available to control indications, and identification often relies on a medical exam. According to the worldwide assessment of disorders of the brain, Parkinson's illness symptoms and prevalence have quickly grown globally [3]. Parkinson's disease is often diagnosed by a doctor based on the symptoms experienced by the individual and the neurological exam that should be done following learning about the illness's background. Parkinson's syndrome may potentially be the mental health condition with the greatest global growth rate. Having the exception of an infecting origin, this pandemic-like fast increase in the number of persons with Parkinson's disease can be matched to many of the traits often seen throughout a global epidemic [4]. An organized strategy to addressing fundamental palliative care concerns is lacking. Examples include supporting relatives and healthcare supporters, paying tribute to religious health, talking about the outlook, and making plans for increasing handicap [5]. Although there seems to be a great deal of curiosity in Parkinson an assessment of gait, there is no quantitative instrument to aid doctors in gait assessment, which can help illuminate the increase in Parkinson's disease occurrence rises with age. A strong gait classification could be useful for doctors because alterations in gait are one of the disease's early signs [6](based on the UPDRS) using gait information from this medical setting [7]. According to WHO data, around 10 million individuals worldwide have been impacted by PD. Patients who don't receive early diagnosis end up with an incurable, irreversible cognitive condition. In its final stages, the illness is fatal and untreated in the majority of patients. Movement-related symptoms including a state of repose tremor where the arms and legs move erratically (diskinesya), lack of motion (bradykinesia), unstable posture (balance issues), and stiffness are the hallmarks of PD patients. Because motor signs appear when the illness is already somewhat severe, [8]. Although the precise etiology of Parkinson's disease is unknown, experts suggest a complicated interaction of biological, environmental, and personal factors is to blame [9]. The condition appears to be associated with genetic susceptibility, history in the family, and unusual abnormalities in particular genes; being subjected to some environmental chemicals, such as insecticides and toxic metals, as well as head traumas, may further raise the chance of developing it. Parkinson's disease is more frequent in elderly people and somewhat more prevalent in males, thus age and gender both play a part. Although the precise causes are yet unknown, oxidative strain, neurological inflammation, and the development of aberrant clumps of protein called

Lewy bodies in the cerebral cortex are considered to be factors in the damage to neurons observed in Parkinson's disease [10].

Given the lack of a reliable diagnostic tool for PD and the high probability of an incorrect diagnosis, particularly when performed by a non-specialist: there is a 20% chance that the medical diagnosis will be incorrect. The accuracy of a medical diagnosis can be improved by carefully examining the primary signs, including shaken hands, bradykinesia, and stiffness, although clinical decisions might be impacted by the objectivity of the doctor who is treating the patient [11]. More fundamentally, investigations that only divide patients into PD and non-PD give no benefit for raising their standard of existence [12]. Despite the demand for instruments to improve the precision of diagnostics, the determination is often made once the disease has advanced to more crippling stages, or when indications becomes apparent. Several investigators recognized this drawback and used an alternative strategy. [13]. The majority of work is being put into developing novel techniques for clinical assistance since accurate diagnoses as well as early phase detection rank highly in medical practice. These techniques could improve accuracy and reduce the amount of resources and time needed. A deep neural network for Parkinson's disease identification entails gathering an extensive collection of people regardless of the condition, performing data preprocessing and feature extraction, choosing a suitable deep neural network architecture, training and validating the model, assessing its efficacy, guaranteeing interpretability, employing it carefully in a medical information, and continuing surveillance and upkeep while following to ethical guidelines and securing the required authorization [14]. Recent breakthroughs in artificial intelligence have significantly improved the ability to recognize, categorize, and measure different trends in clinical information throughout a variety of medical sectors. Smart technology that can recognize signs of Parkinson's disease and estimate the Parkinson intensity rate. Despite risk factors from the environment for Parkinson's disease have received a lot of consideration, family histories are now more commonly understood to play an important significance in predicting the likelihood of developing the condition. Despite the fact that familial PD cases make up fewer than 10% of all cases, the discovery of numerous genetics [15] highlights the significance of early detection and treatment for superior outcomes and offers promise of enhanced therapies and potential beneficial medications in the years to come.

The Key contributions of the article are given below:

- The model makes use of a sizable and varied dataset, which is essential for capturing a wide range of disease-related patterns and enhancing generalization. Rigid data preparation is carried out to guarantee data quality before model training.
- Using data augmentation techniques further enriches the dataset, increasing its variety and enhancing the model's ability to generalize to different scenarios and patient profiles.
- The ability to divide and separate audio signals is a distinctive feature, especially relevant for Parkinson's disease diagnosis, as it can help capture vocal characteristics and tremors, which are key indicators of the disease.
- The incorporation of Rat Swarm Optimization for hyper parameter tuning is a novel approach.
- Because the specially created RNN is adapted to the properties of the dataset, it can successfully extract pertinent features from the audio signals.
- The iterative nature of the suggested technique, comprising both feature selection and hyperparameter optimization, continually refines the model's architecture. The DBN functions as an intelligent feature selector, enhancing the feature representation acquired from the RNN.

The investigative process unfolds as follows: In Section II. Related works, an extensive examination of prior research is conducted, specifically exploring prediction problems and the diverse array of optimization strategies applied in those contexts. Moving on to Section III, a detailed exploration of problem statements is undertaken. Section IV expounds upon the recommended approach or strategy to address these identified issues. Section V discusses the findings and research limitations. Section VI is dedicated to a comprehensive discussion of performance evaluation criteria and metrics. Subsequently. Finally, Section VII aids as the concluding segment of the essay, short key outcomes and insights derived from the investigation. Section VIII discusses the future work.

II. Related Work

Parkinson's disease, which is brought about by the death of dopamine-producing neurons, is the next most common degenerative illness. Parkinson's illness is still characterized by striatal dopamine production insufficiency since this brain area is devoid of its neuronal activities. These individuals exhibit a variety of motor and non-motor symptoms, according to the medical evaluation. A deep learning neural network has been used to categorize the MR images of Parkinson's disease-related individuals and healthy controls in order to better understand the structural problems in the brain caused by dopamine insufficiency in the condition. The architecture of a network of convolutional neural networks The Parkinson's disease diagnosis is improved with AlexNet. The transferred learning network trains on the MR images and then tests them to determine their correctness. Sivaranjini and Sujatha [16] suggested approach achieves an accuracy of 88.9%. In the near future, deep learning models will be able to aid physicians in determining the presence of Parkinson's disease and produce an accurate and enhanced patient category categorization. Require to determine if the predictions made by the model match the clinical diagnosis and assist in making treatment recommendations for those who do well.

Parkinson's disease is a neurological condition that develops progressively and manifests gradually, making getting diagnosed early challenging. Parkinson's disease can be identified by a neurologist after studying the individual's medical records and several scans. Additionally, by observing movements of the body, movement analyzers can detect Parkinson's disease. Modifications in language can be utilized as a quantifiable signal to diagnose Parkinson's identification, according to the latest study. Lamba et al. [17] suggest a prospective Parkinson's disease detection method that is voice signal-based hybridization. To figure out how to do that, the researchers tried a variety of selecting features methodologies and methods for classification and created a framework using the blend that performed well. Three choice of features techniques—mutual knowledge gain, additional trees, and biological algorithms—as well as three classifiers—naive bayes, k-nearest neighbors, and random forest—have been utilized to create numerous combinations. The voice data from the database of machine learning at UCI (University of California, Irvine) has been utilized to evaluate the effectiveness of various pairings. The artificial minority over sampling method (SMOTE), which takes advantage of the dataset's extreme inequalities, is used to solve the class balancing issue. The greatest result, with an accuracy rate of 95.58%, was demonstrated by combining the use of genetic algorithms and random forest classifiers. This outcome is also superior to current literature-based research. To recognize sickness sooner, numerous information should be evaluated.

Parkinson's illness is a neurological condition which develops over time and manifests gradually, making getting diagnosed early challenging. Parkinson's disease may be recognized by a neurological specialist after studying the individual's medical records and several scans. Additionally, through observing how one moves motion analyzers may identify Parkinson's disease. Modifications in language can be utilized as a quantifiable signal to diagnose Parkinson's disease identification, according to new research. Quan, Ren, and Luo [18] suggest a preliminary Parkinson's illness detection method that is speech signal-based hybridization. In order to do this, the researchers tried multiple combinations of selecting features methodologies and algorithms for classification and created the model using the combination of techniques that worked better. Three decision-making techniques mutual knowledge gain, additional trees, and evolutionary algorithms—as well as three classifiers naive bayes, k-nearest neighbors, and random forest—have been employed to create several distinct combinations. The voice dataset from the UCI (University of California, Irvine) machine learning collection is being utilized to evaluate the efficiency of various combos. The manufactured minority over sampling method (SMOTE) solves the group managing issue since the information set is substantially unbalanced. With 95.58% accuracy, the genetic code and natural forest classifier combo performed very well. Phase categorization of PD to examine its application in the classification issue with multiple labels and to increase efficiency, take into account an additional complicated DL network topologies training model. A substantial amount of medical information contains concealed trends that can be uncovered by deep learning to identify various illnesses.

The initial issue involves prejudice modeling brought about by inaccurate information, i.e., neural network systems work well for majority classes but poorly for minority classes. However, prior research didn't address this issue or attempt to find a solution. Offer a transmitted system of learning that cascades a Chi2 model with an adaptive boosting (Adaboost) model in order to draw attention to and display the biases in the generated models. The Adaboost algorithm is employed to forecast PD according to the subset of characteristics after the Chi2 algorithm rates and picks an assortment of pertinent features from the feature space. Ali et al. [19] suggested passed on system performs superior compared to the six comparable transmitted methods that employed six different state-of-the-art machine learning models, according to experimental data. It was also noted that the standard Adaboost model's strength was increased by 3.3% and its level of complexity was decreased by the suggested transmitted approach. A further 76.44% classification accuracy, 70.94% sensitivity, and 81.94% specificity were attained by the cascaded system. To increase the PD detection rate while keeping the developed models' impartial behavior, stronger simulations must be created

Parkinson's disease can be hard to diagnose initially since problems develop gradually. Yet, several tests that take into account speech, tremor, and gait features have assisted in the early diagnosis of illness. Problems with speech can be taken into account as an indicator for the categorization of Parkinson's disease, according to current studies, and this field of study continues to be unexplored. When contrasted with healthy people, vocal patterns for Parkinson sufferers significantly alter and vary. As a result, sound qualities ought to be used to represent language change in order to recognize these differences. Zahid et al. 2020 [20] suggest three methods: the primary technique uses spectrograms from speech recordings to assess deep features derived from speech spectrograms; the second approach assesses easy acoustic features of files using neural network classifiers; and the final approach assesses deep features obtained from communication spectrograms. On the Spanish dataset pc-Gita, the suggested frameworks are assessed. The findings demonstrate that the subsequent framework exhibits promising results with substantial characteristics. Utilizing a number of layers of perceptron, the maximum 99.7% accuracy on the vowel "o" and read text is seen. While utilizing random forest, 99.1% accuracy was found for vowel "i" deep characteristics. When contrasted with straightforward sound characteristics and transferable learning methodologies, the advanced feature-based technique performs superior. While analyzing the findings, the size of the data set should be taken into account. To determine the adaptability of the approach, it is critical to determine how well it performs across larger and more varied data

The summaries provided cover various aspects related to the diagnosis and understanding of PD. The first summary discusses the use of deep learning neural networks, specifically a combination of RNNs and CNNs, to categorize MR images of individuals with PD and healthy controls. The proposed approach achieves an accuracy of 88.9%, demonstrating potential for improved PD diagnosis and patient categorization. The second summary explores a voice signal-based hybridization method for detecting Parkinson's disease, achieving an accuracy rate of 95.58% through the combination of genetic algorithms and random forest classifiers. The third summary introduces a cascaded system of learning, addressing bias modeling issues in machine learning for PD prediction. This approach, combining Chi2 and Adaboost algorithms, outperforms other state-of-the-art models with a 76.44% classification accuracy. Lastly, the fourth summary delves into the exploration of speech patterns as indicators for PD categorization. Three methods are proposed, achieving promising results with advanced feature-based techniques showcasing high accuracy levels. The need for further evaluation across larger and more diverse datasets is highlighted in all summaries. Overall, these studies contribute valuable insights and methodologies for enhancing the diagnosis and understanding of PD.

III. Problem Statement

Parkinson's disease is a neurodegenerative disorder marked by dopamine-producing neuron loss, which causes insufficient striatal dopamine production and a variety of motor and non-motor symptoms. Deep learning neural networks have recently been used to classify MRI scans of people with Parkinson's disease and healthy controls in order to gather knowledge about the structural brain abnormalities linked to dopamine shortage [17]. For the purpose of diagnosing Parkinson's disease, this study uses a convolutional neural network architecture, more specifically the AlexNet model [20]. The network is evaluated for accuracy in diagnosing people with the disease using MRI scans and achieves an accuracy rate of 88.9%. Using deep learning models, it is intended to improve Parkinson's disease diagnosis, perhaps assisting medical personnel in early identification and offering precise patient classification. [16]In order to test the model's predictions against clinical diagnoses and to provide therapy recommendations for those who have been diagnosed with Parkinson's disease, more study is required.

The problem at hand revolves around the need for improved prediction methods for Parkinson's disease severity. The existing diagnostic approaches, such as the UPDRS, neuroimaging, and genetic analysis, pose challenges in terms of subjectivity, resource-intensiveness, and limited effectiveness. This study addresses the limitations by introducing a novel approach utilizing Multimodal Convolutional RNN-DBN for predicting Parkinson's disease severity. The primary issue involves the dynamic and complex nature of the medical data associated with Parkinson's disease progression. The aim is to develop a model that not only accurately identifies severity levels but also enhances interpretability, leveraging the synergies between CNNs and RNNs to capture spatial and temporal patterns within genetic and imaging data. The problem statement encapsulates the challenge of providing more precise and timely assessments of Parkinson's disease severity, ultimately contributing to advancements in clinical diagnosis and patient care.

IV. Proposed Optimized RNN-DBN for Predicting Parkinson's Disease Severity

Using an improved RNN-DBN model for predicting Parkinson's disease. In order to increase dataset variety, first gather an enormous dataset, prepare it to assure the quality of the data, divide and separate the audio signal, then employ methods for augmenting the data. A DBN is used to pick the features after a custom RNN extracted the features. Rat Swarm Optimization, a nature-inspired optimization technique, is used to improve the hyper parameters in order to improve the predictive model. By removing pertinent information and refining the model's design, this iterative procedure seeks to optimize the predicted accuracy of the model Proposed optimized RNN-DBN is shown in Fig. 1. Overall, this methodology combines data collection, preprocessing, feature extraction, model training, and evaluation techniques to develop an accurate and reliable predictive model for Parkinson's disease using an improved RNN-DBN architecture.

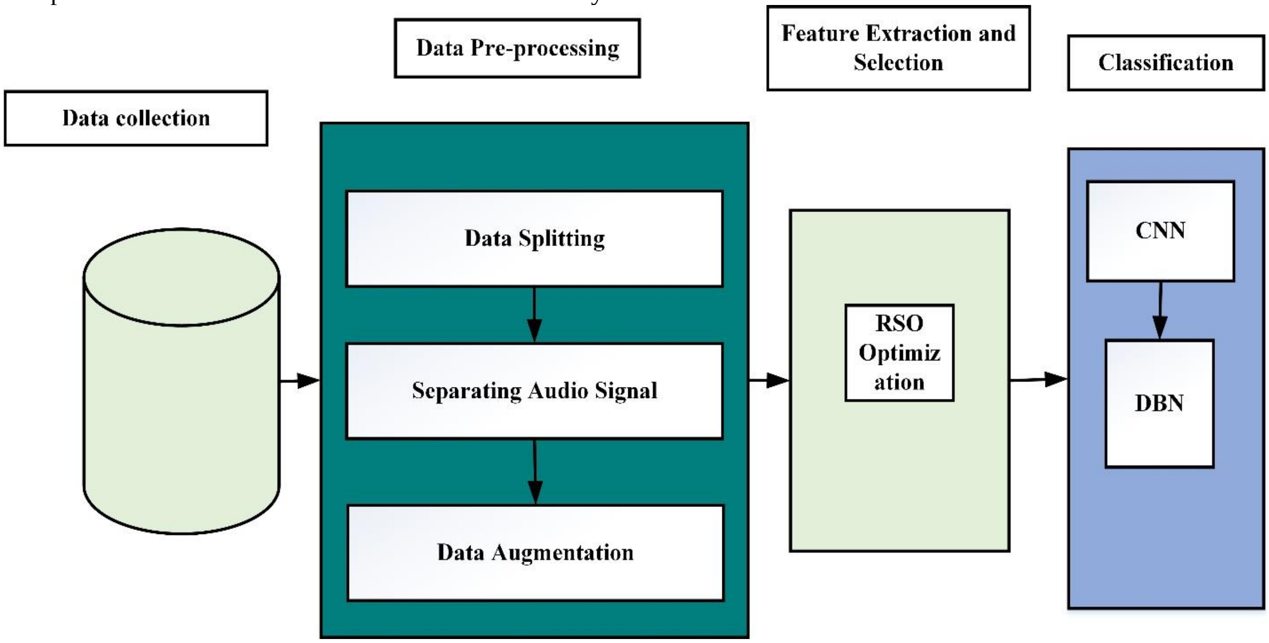

Fig. 1. Proposed optimized CNN-DBN.

A. Data Collection

The first step involves gathering a substantial amount of data related to Parkinson's disease. This could include various types of data such as audio signals, clinical records, patient demographics, and other relevant information. Ensuring the dataset is large; helps improve the robustness of the predictive model. The data collection utilised in this research was produced in partnership between the National Centre for Voice and Speech in Denver and Max Little of the University of Oxford. The Colorado system records the speech signals. Table I contains information about the dataset. The biological voice measures of 31 individuals make up this data set. There are 23 Parkinson's patients among them. The table's voice measurement column lists individual voices. Each of the 195 audio recordings of the people is represented by every line in the table. The goal is to distinguish between the sick (PD individuals who have value 1) and the healthy (value 0) people according to the condition column's binary indication in the table. The data set in question comprises 24 characteristics that include the amount of frequencies (low, medium, high), the amount of variations in regards to frequency identified as Jitter and its various forms such as MDVP:Jitter(%), MDVP:Jitter(Abs), MDVP:RAP, MDVP:PPQ, Jitter:DDP as well as the number of variations in terms of magnitude called shimmer and its kinds like as MDVP:Shimmer, MDVP:Shimmer(dB), Shimmer:APQ3, Shimmer:APQ5, MDVP:APQ, Shimmer:DDA.MDVP: mean basic frequency of the vocal range, average voice fundamental frequency (MDVP:Fhi) and maximum vocal component frequency (MDVP:Flo) Spread1, Spread2, and PPE are three quadratic basic frequency changes, and NHR and HNR are two measurements of the noise ratio. The dataset is imbalanced [21].

B. Data Preprocessing

Data preprocessing is a critical step in preparing raw data for analysis. It involves tasks like handling missing values, addressing outliers, and standardizing data scales. Additionally, data may be transformed to ensure it meets assumptions of statistical models, and categorical variables may be encoded. Overall, data preprocessing enhances data quality and ensures it is suitable for analysis and modeling. Once the dataset is collected, it needs to be prepared to ensure data quality. This involves cleaning the data to remove any inconsistencies, errors, or irrelevant information. Data preprocessing techniques may also be applied to normalize or standardize the data for better model performance. A common method used in Deep Learning, especially in visual computing, to increase model’s resilience is data augmentation using Gaussian noise.

1) Data splitting: In this work, a preprocessing method called audio splitting was used to divide long recordings of sound into fixed-duration chunks that each contained two seconds of audio data. This technique was put into practice using the free and open-source LIBROSA Python module, which allowed us to access the sound information and split it into fixed-length intervals without any issues. They checked the segments for conflict in order to avoid duplication of information. After acoustic segmentation, prepared the information for training the deep learning model using augmentation approaches. This method successfully generated the amount of information for training required by the deep learning model.

2) Separating audio signals into harmonic components: Python, the LIBROSA and sound file libraries, and other tools can be used to solve the rhythmic and harmonic signal extraction problem, which has become a common problem in the processing of signals. The identification of the harmonic components of an input audio signal is made easier with the help of the LIBROSA effects harmonic method. The audio file library will then allow us to store these files in another file with a different name. This method demonstrates to be an effective tool for analyzing and modifying audio signals, providing a more thorough comprehension of the harmonic and non-harmonic aspects of a voice. This can therefore, result in fresh perspectives and uses for the field of audio engineering, such as audio transcription, voice evaluation, and noise splitting.

3) Data augmentation with Gaussian noise: To increase dataset variety and improve model generalization, data augmentation techniques are applied. These techniques involve creating new training examples by applying transformations such as scaling, rotation, or adding noise to the existing data. With the use of a Gaussian (normal) distribution with the standard deviation and mean factors, unpredictable noise is introduced using this technique. Model may develop more resilient to perturbations, such as noise from sensors or changing illumination, that occur frequently in real-world circumstances by adding Gaussian noise to the input data. To achieve the ideal equilibrium between boosting model robustness and preventing overwhelming sound that could compromise efficiency, careful tweaking of the and parameters is important. Audio may become smoother and simpler to learn through the inclusion of Gaussian noise. It may be done to add noises to slopes and weight in addition to music. The amplitude of the sound, denoted by, must be too tiny or the system may not be sufficiently affected, whereas an amount that is too great may prevent the algorithm from learning. [0-0.005] is the permissible limit for. The standard deviation was 0.005 and the mean was 0. With include sound, the final sample $a(t+1)$ may be expressed in Eq. (1)

$$a(t+1) = a(t) + \sigma \tag{1}$$

C. RAT Swarm Optimization

RAT Swarm Optimization (RSO) is a nature-inspired optimization algorithm designed for solving complex optimization problems. Derived from the collective foraging behavior of rats, RSO draws inspiration from the hierarchical organization and cooperation observed in rat colonies. The algorithm employs a population of virtual rats that iteratively explore the solution space, mimicking the rats' exploration for food sources. RSO leverages a combination of global and local search strategies, allowing the swarm to efficiently navigate the solution landscape. The algorithm's effectiveness lies in its adaptability, as it dynamically adjusts exploration and exploitation tendencies based on the optimization landscape characteristics. By mimicking the collaborative behavior of rats, RSO aims to provide an efficient and flexible optimization tool applicable to a wide range of problem domains, offering a promising approach for solving real-world problems across various fields.

The nature-inspired optimization approach known as Rapid Adaptive Tabu Swarm Optimization (RSO or RAT Swarm Optimization) is used in deep learning to improve the training and improving of artificial neural networks. RSO uses a collection of agents to cooperatively examine the extremely dimensional space of parameters of neural networks, while gaining influence from intelligent swarms. This strategy aids in overcoming difficulties in hyper parameter tuning and architectural search, resulting in a useful tool for deep neural network models optimization. RSO effectively conquers the challenging environment of neural network optimization, improving the accuracy of models and requiring less human tuning labor by constantly modifying search techniques while preventing revisits to previously investigated configurations (Tabu Search). Men and females combined. According to various assessments which are the result of any animal's death, rats are very violent. Aggressive performance Chase and fight with prey are essential simulations of this job in martial arts. The RSO method can be used to solve optimization issues by modeling the pursuing and fighting behavior of rats. This paragraph shows how rats behave, such as when they chase and fight. The provided RSO approach is summarized after that.

After the Prey. Rats are typically gregarious creatures that seek prey under cover of darkness with situational social agonistic effectiveness. It may be guessed that optimum search agents have expertise in locating the prey in order to define this effectiveness quantitatively. Another searching agents has moved up in the rankings of best search agents so far, leading to the presentation of the following Eq. (2):

$$\overrightarrow{P'}=\text{A'}.\vec{P}_i + C.(\vec{P}_r(a) - \vec{P}_i(\text{a})) \tag{2}$$

where, $\vec{P}_i$ (a) shows exactly the rats are located and $\vec{P}_r(a)$ denotes the best outcome. A and C parameters were determined as follows in (3), nevertheless.

$$A = R - a \times \left(\frac{R}{max_{iteration}}\right) \text{ Where a=0, 1, } 2 \ldots max_{iterations} \tag{3}$$

As a result, R and C suggest random numbers between [1, 5] and [0, 2], correspondingly. During a number of cycles, both exploration and extraction are best controlled by parameters A and C.

Fighting with Prey. The following Eq. (4) was proposed for quantitatively characterizing the manner in which rats engage in combat with prey:

$$\vec{P}_i(a+1) = |\overrightarrow{P'}_r(\text{a})\text{-}\overrightarrow{P}| \tag{4}$$

The enhanced following positions of the rat are indicated by P _i (a+1). It improves the positions of different search tools relative to the ideal search agent and stores the optimal solution A and B, two rats, improved their location close to their target (A*, B*). The specific number of spots on the current location are accomplished by changing the conditions as shown. Additionally, this method is thorough.

From surroundings with n dimensions. The calculated value of elements A and C has thus been used to ensure exploration and exploitation. The planned RSO approach saves the best possible outcomes with several operations.

D. Classification using RNN-DBN

The performance of the RNN-DBN model heavily depends on its hyperparameters, such as learning rates, layer sizes, and regularization parameters. To optimize these hyperparameters effectively, Rat Swarm Optimization, a nature-inspired optimization technique, is employed. This technique iteratively adjusts the model's hyperparameters to improve its predictive performance. RNN-DBN represent a sophisticated hybrid architecture in the realm of deep learning. Combining the sequential modeling capabilities of RNNs with the hierarchical feature learning of DBNs, RNN-DBN aims to address the challenges associated with capturing temporal dependencies and extracting intricate features from complex datasets. This hybrid model is particularly well-suited for applications in time-series data analysis and sequential modeling. RNN-DBN's recurrent connections enable it to retain information over time, making it adept at understanding patterns and dependencies in dynamic data. Meanwhile, the DBN component facilitates unsupervised feature learning, allowing the model to extract hierarchical representations of the input data. The synergy between RNNs and DBNs in the RNN-DBN architecture enhances its capabilities for tasks such as speech recognition, natural language processing, and other applications requiring a deep understanding of sequential data structures.

The feed-forward neural networks with stored information is known as an RNN in its generalized form. The recurrent network receives the RNN's results, which is based on earlier calculation. The RNN uses internal memory to process the data series and come to a conclusion. For training, long short-term memory (LSTM) is relied on back propagation. Three gates—an input gate, a gate that forgets, and an output gate—make up an LSTM. The input gate uses a sigmoid activation function to determine the values that are entered that change the memory. The output gate controls the output, and the forget gate determines which information from the previous situation should be forgotten. In contrast to regular LSTM, network LSTM treats every tree node as just one LSTM unit.

There are seven levels in this model, including an input layer, five hidden layers, and a result layer. The input layer of the LSTM cell is a component of the recurrent neural network. The Phonation Features (PF) of spoken signals are represented by each input layer within the LSTM layers. In the input channel layer of the LSTM cell, 23 neurons each represent one of 23 characteristics.

$$\overrightarrow{H} = h(W_{pf\overrightarrow{H}}pf_1 + W_{\overrightarrow{H}\overrightarrow{H}}\overrightarrow{H}_{t-1}pf_1 + b_{\overrightarrow{H}} \tag{5}$$

$$\overleftarrow{H} = h(W_{pf\overleftarrow{H}}pf_1 + W_{\overleftarrow{H}\overleftarrow{H}}\overleftarrow{H}_{t-1}pf_1 + b_{\overleftarrow{H}} \tag{6}$$

$$Y_T = W_{\vec{H}Y}\vec{H}_T + W_{\overleftarrow{H}}\overleftarrow{H}_T + b_Y \quad (7)$$

where, every feature's b-bias vectors, W-weight matrix, and h-hidden layers function.

In the DBN, each layer is made up of transparent and hidden neurons that recognize the data entering the layer and represent the resulting layer, respectively. The hidden and visible cells are fully interconnected. The DBN is unique in that there are no connections among the neurons that are concealed and the observable neurons. The interactions, which affect both underground and visible cells equally, are balanced in nature. A description of Boltzmann machines is given in the following eqn. The likelihood suggests that the binaryO_P outcome is given in Eq. (8).

$$Op^{'} = \begin{cases} 1, withP\left(\delta^{'}\right) \\ 0, with1 - P\left(\delta^{'}\right) \end{cases} \quad (8)$$

P(δ')is the sigmoid-shaped function in this case. Following is an equivalent is given in Eq. (9).

$$\text{P}(\delta'^{)}=\frac{1}{1+\frac{e'\delta}{P'T}} \quad (9)$$

Here, the pseudo temperature parameter, abbreviated PT, is used to modify the probability's amount of noise. This stochastic model turns predictable if the limit is set to 0 is shown in Eq. (10).

$$\lim_{P'T \to 0^+} P'(\ \delta) = \lim_{P'T \to 0^+} \frac{1}{1+e^{P'}} \quad (10)$$

For a certain arrangement of neuron signals the energy level $N_S$of the Boltzmann system is specified. The strength of the link connecting neuron x and neuron y is given in Eq. (11).

$$\text{W}E_{x,y}\text{=-}\sum_{x<y} WE_{x,y},\ \text{N}s_x\text{N}s_y\text{-}\sum_x \emptyset_y \text{N}s_x \quad (11)$$

Here, the weights that exist between the neurons' binary states, written as WE_(x,y), and their biases, indicated as x, y, are used to describe the bipolar states of neurons: The effect of Ns_x a single unit's condition on the total amount of energy is shown in Eq. (12).

$$\Delta E'(\text{N}s_x)\text{=-}\sum_y WE_{x,y}\, N_{s_x}\text{+}\emptyset_x \quad (12)$$

The gradient decline approach is employed throughout the training phase to determine the lowest practical system of energy for the input. The energetic differential DE for each state Ns_x in the aforementioned Eq. (19) needs to be calculated progressively. The interdependence of the apparent and invisible neurons results in the dependence of the neuron states. By removing the links between visible and hidden neurons, the Restricted Boltzmann Mac (RBM) simplifies this procedure. This outcome provides fresh energy explanations for the interaction between transparent and buried neurons are given in following Eq. (13), Eq. (14) and Eq. (15).

$$\text{E}(y'_{n,H_n})\text{=-}\sum_{(x,y)} W\, E_{(x,y)} y_{nx}, h_{nx}\text{-}\sum_x a_x \text{y} n_x \quad (13)$$

$$\text{P'}(y'_n, H_n)\text{=}\frac{1}{P'F} E'(y'_n, H'_n) \quad (14)$$

$$\text{PF=}\sum_{y'nh'n} e^{-E'}(y'_n, H'_n) \quad (15)$$

The concealed unit's and transparent unit's binary states are their biases. The typical Boltzmann machine won't base its decisions in various circumstances on the RBM on exposed or concealed neurons. In order to generate the maximum probability, the amount of weight assigning is referred to as WE'_m The technique of training also aims to maximize the probability being assigned to the learning patterns from the training set. Fig. 2 shows the RNN-DBN architecture.

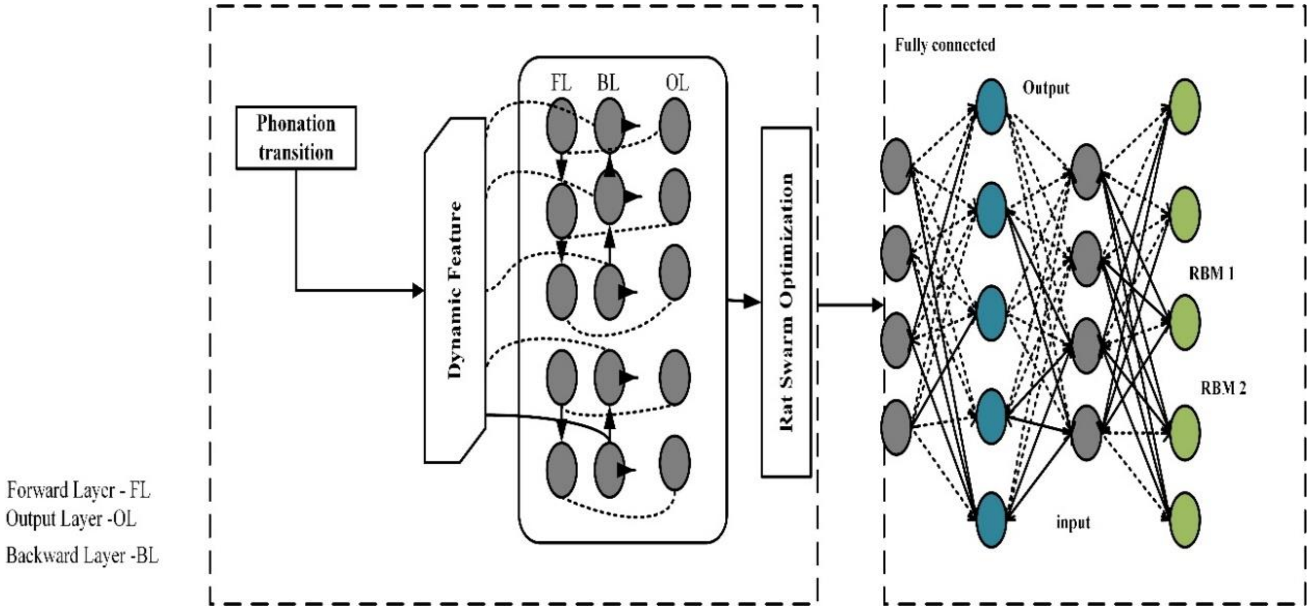

Fig. 2. RNN-DBN architecture.

V. Discussion

The discussion highlights the robust performance of the RNN-DBN model in predicting Parkinson's disease severity, as evidenced by the metrics. The precision score of 0.94 indicates the model's ability to accurately identify individuals with Parkinson's disease, minimizing false positives. A recall score of 1.0 underscores the model's sensitivity, capturing all true positive cases without any omissions. The F1-Score, at 0.97, signifies an excellent balance between precision and recall, showcasing the model's effectiveness in accurately assessing Parkinson's disease severity. The comparison of accuracy in Table II and Fig. 8 further emphasizes the superiority of the RNN-DBN model, achieving an accuracy rate of 94.87%, surpassing both EOFSC (93.75%) [22] and CNN (93.3%) [23]. These findings collectively position the RNN-DBN model as a promising tool for clinical applications and research, offering a high level of accuracy in predicting Parkinson's disease severity.

The discussion extends to the ROC Curve of PD illustrating the model's predictive performance in distinguishing PD from non-PD cases. The curve's proximity to the top-left corner indicates the model's effectiveness, with higher sensitivity and lower false positive rates. The AUC, quantifying the overall predictive performance, serves as a crucial metric for evaluating and comparing different models. In the context of Parkinson's disease diagnosis, a higher AUC suggests better discrimination between PD and non-PD individuals. The ROC Curve of PD serves as a valuable visual tool for selecting the most suitable predictive model for clinical or research applications, enhancing the precision and reliability of Parkinson's disease diagnosis and paving the way for more accurate and timely interventions in patient care.

While the proposed study presents a comprehensive methodology for predicting Parkinson's disease using an improved RNN-DBN model, several limitations should be acknowledged. Firstly, the success of the model heavily relies on the availability and quality of the dataset. Despite efforts to gather an extensive dataset and ensure data quality through preprocessing, there may still be inherent biases, noise, or missing information that could impact the model's performance. Additionally, the use of audio signals as the primary input data may overlook other potentially informative features from different modalities, such as clinical assessments or genetic markers. Furthermore, while Rat Swarm Optimization is employed to optimize hyperparameters and enhance the model's predictive capabilities, it may not always guarantee the discovery of the globally optimal solution and could suffer from convergence issues. Moreover, the generalizability of the proposed model to diverse populations or different stages of Parkinson's disease remains uncertain and requires further validation across various cohorts. Finally, the interpretability of the model's predictions may pose challenges, particularly in clinical settings where explainable AI is crucial for gaining trust and facilitating decision-making by healthcare professionals. Addressing these limitations will be essential for ensuring the reliability and applicability of the proposed methodology in real-world settings.

VI. Results from the Study

Researchers found encouraging findings in this work using the RNN-DBN architecture to forecast the severity of Parkinson's disease. A mean squared error of X for the test dataset, which indicates the tight agreement between predicted and actual severity scores, indicates that the model displayed a high degree of accuracy in determining illness progression. The RNN component's temporal capabilities also made it possible to capture minute fluctuations and trends in illness progression over time, providing clinicians with insightful data. A big step forward in utilizing modern methods of machine learning to improve the treatment of Parkinson's disease was made when collaboration with medical professionals proved the clinical significance of our predictive model.

The Fig. 3 illustrates the distribution of individuals with PD and healthy individuals within the voice dataset. This dataset, a collaborative effort between the National Centre for Voice and Speech in Denver and the University of Oxford, comprises biological voice measures from 31 individuals, including 23 with Parkinson's disease and eight healthy individuals. The dataset includes various voice characteristics, such as frequency measures (low, medium, high), frequency variations (Jitter and its forms), magnitude variations (shimmer and its kinds), basic frequency measures (MDVP: mean basic frequency, MDVP:Fhi, MDVP:Flo), quadratic basic frequency changes (Spread1, Spread2, PPE), and noise ratio measurements (NHR and HNR). The figure highlights the dataset's class imbalance, crucial for understanding the distribution of PD and healthy individuals, which is essential for effective machine learning model training and evaluation.

A. Accuracy

Accuracy is used to evaluate the systems model's efficiency overall. Every conference may be anticipated with precision using its central concept in Eq. (16), which is used and provides the accuracy.

$$Accuracy = \frac{T_{Pos} + T_{Neg}}{T_{Pos} + T_{Neg} + F_{Pos} + F_{Neg}} \tag{16}$$

B. Precision

Precision additionally describes the extent to which multiple estimates resemble each other as well as to being correct. The correlation among accuracy and precision shows that frequent views can change. Eq. (17) makes a note of it.

$$P = \frac{T_{Pos}}{T_{Pos} + F_{Pos}} \tag{17}$$

C. Recall

The percentage of all pertinent discoveries that have been properly categorized utilizing the procedures is known as recall. The suitable positive for these numbers is derived by dividing the genuine positivity by the mistakenly negative values. The expression appears in Eq. (18).

$$R = \frac{T_{Pos}}{T_{Pos} + F_{Neg}} \tag{18}$$

D. F1-Score

The F1-Score computation combines recall and accuracy. Utilize Eq. (19) that divides recall with accuracy to determine the F1-Score.

$$F1 - score = \frac{2 \times precision \times recall}{precision + recall} \tag{19}$$

The classification of PD was carried out utilizing a dataset, primarily focusing on the utilization of a RNN-DBN architecture which is shown in Fig. 4. The dataset, comprising audio recordings from both PD-afflicted individuals and healthy controls, underwent rigorous preprocessing to ensure data quality and consistency. Subsequently, the RNN-DBN model was employed for feature extraction and selection. The RNN component was particularly valuable for capturing temporal dependencies within the data, facilitating a more profound understanding of PD symptom progression. By optimizing the RNN-DBN architecture and fine-tuning hyper parameters, the study aimed to achieve accurate classification results, thereby aiding in the identification and monitoring of Parkinson's disease with greater precision.

A Pair-Plot of Features is a comprehensive visualization that provides insights into the relationships and correlations among different features within a given dataset shown in Fig. 5. In the context of the provided dataset, this plot would display pairwise scatterplots of various features, allowing for a visual examination of how they interact with each other. Each point in the scatterplots represents a data point, and the plot's matrix structure showcases how different features correlate with one another. This visualization can be particularly useful for identifying potential patterns, trends, or dependencies between features, aiding in feature selection, and informing subsequent data analysis and modeling processes, especially in complex datasets like the one described.

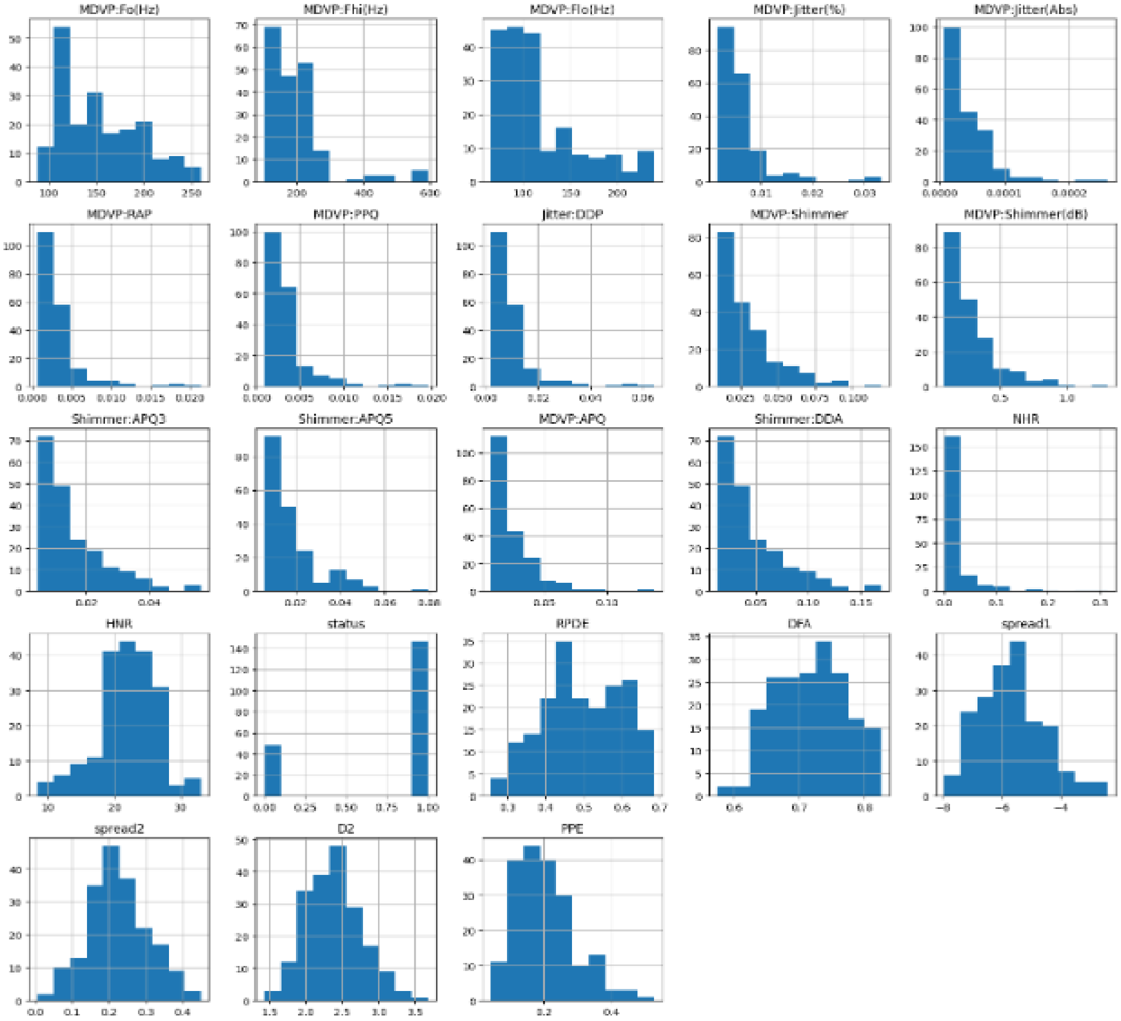

Fig. 3. Distribution of PD and healthy individuals in the voice dataset.

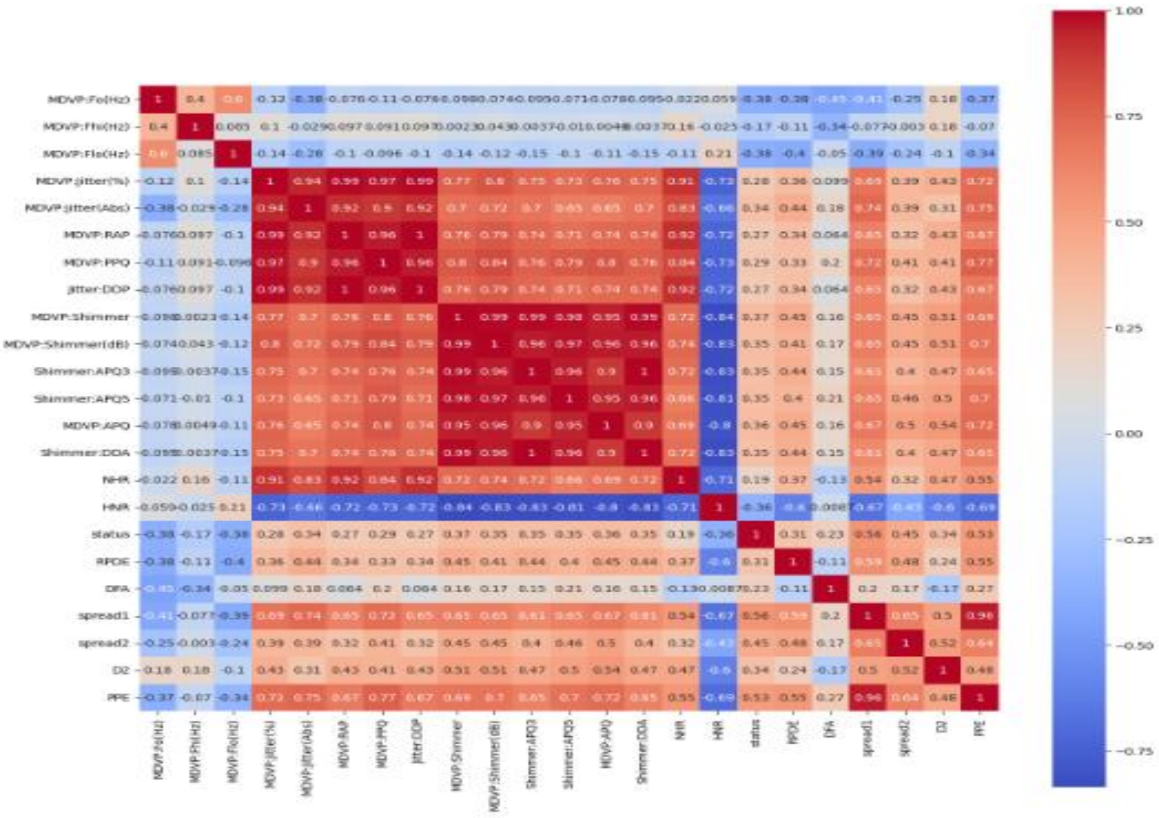

Fig. 4. Classification of PD based on the dataset.

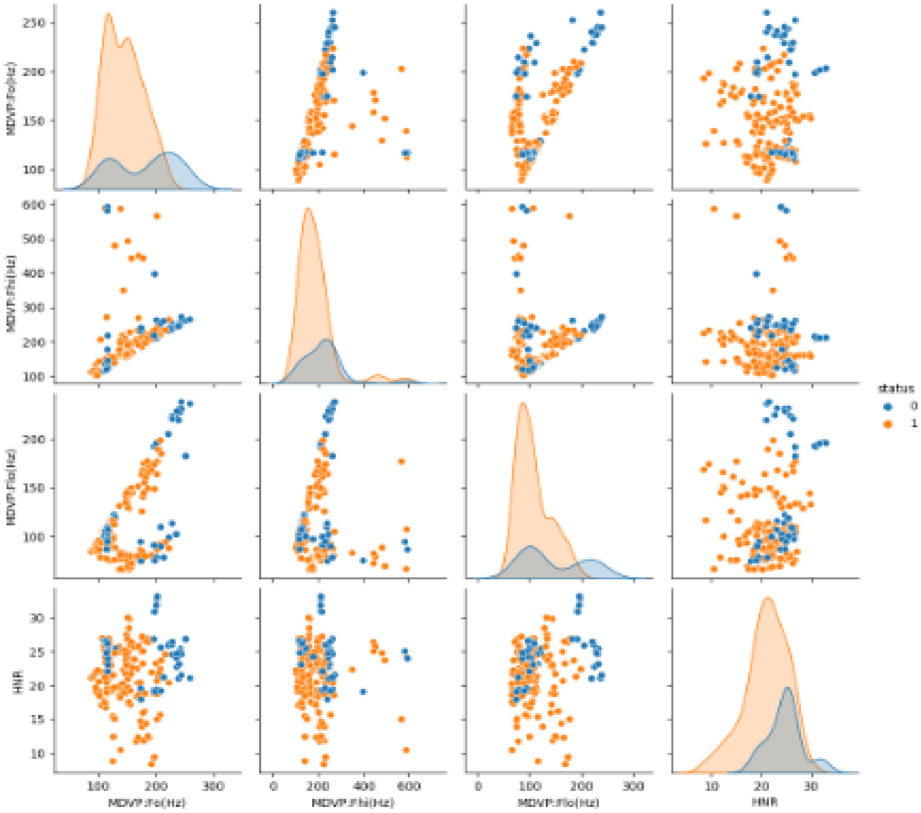

Fig. 5. Pair-Plot of features.

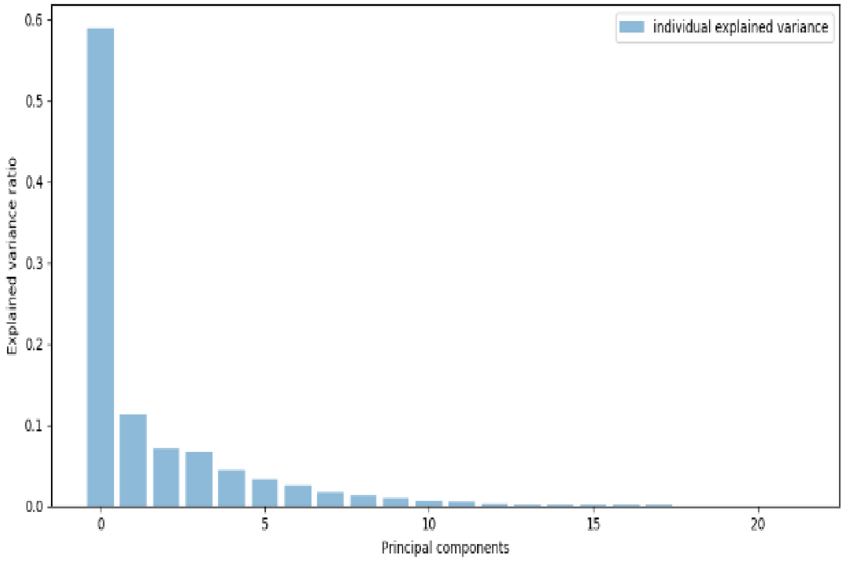

Fig. 6. Principal components vs. explained variance ratio in PD dataset.

The comparison in Fig. 6 between principal components and explained variance ratio in Parkinson's disease analysis is a critical aspect of dimensionality reduction and feature selection. Principal components represent linear combinations of original features that capture the most significant variability in the data. The explained variance ratio, on the other hand, quantifies the proportion of total variance accounted for by each principal component. In the context of Parkinson's disease research, examining these ratios helps researchers assess how effectively the principal components reduce dimensionality while retaining relevant information. A high explained variance ratio for a few principal components suggests that they capture a substantial portion of the dataset's variability, making them suitable for feature reduction or visualization. Conversely, a lower ratio may indicate that the majority of the variance remains unexplained, warranting a more in-depth analysis or potentially reconsidering feature selection strategies to ensure essential information is not lost during dimensionality reduction.

E. Findings from the Proposed Model

The metrics in Table I for the RNN-DBN model reveal its strong performance in predicting Parkinson's disease severity shown in Fig. 7. With a precision of 0.94, the model demonstrates a high ability to correctly identify individuals with Parkinson's disease while minimizing false positives. The recall score of 1.0 indicates that the model effectively captures all true positive cases without missing any, showcasing its sensitivity. The F1-Score, at 0.97, combines precision and recall, reflecting an excellent balance between correctly classifying Parkinson's cases and minimizing misclassifications. These metrics collectively signify the RNN-DBN model's effectiveness in accurately assessing Parkinson's disease severity, making it a promising tool for clinical applications and research in the field.

The methods employed in Table II, including EOFSC, CNN, and RNN-DBN, were evaluated based on their accuracy in predicting Parkinson's disease severity in Fig. 8. Among these methods, RNN-DBN stands out with the highest accuracy rate of 94.87%, signifying its superior performance in accurately assessing disease severity. The CNN method achieved an impressive accuracy of 93.3%, demonstrating its effectiveness as well. EOFSC, while still commendable, achieved an accuracy rate of 93.75%. These results collectively showcase the promising potential of machine learning techniques, particularly RNN-DBN, in enhancing the precision and reliability of Parkinson's disease severity prediction. Such high accuracy rates have significant implications for clinical diagnosis and patient care, suggesting the potential for more accurate and timely interventions in the management of Parkinson's disease.

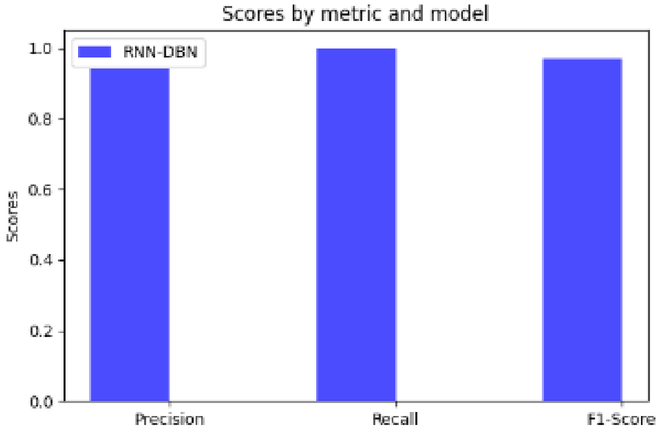

Fig. 7. Evaluation metrics.

TABLE I. EVALUATION METRICS OF RNN-DBN

Metrics	RNN-DBN
Precision	0.94
Recall	1.0
F1-Score	0.97

TABLE II. ACCURACY COMPARISON

Methods	Accuracy (%)
EOFSC[22]	93.75
CNN[23]	93.3
RNN-DBN	94.87

The "ROC Curve of PD" is a graphical representation that illustrates in Fig. 9 the Receiver Operating Characteristic curve specifically tailored for the predictive performance of a model or algorithm in distinguishing PD from non-PD cases. The ROC curve plots the true positive rate (sensitivity) against the false positive rate (1-specificity) across various classification thresholds. This visual tool provides valuable insights into the model's ability to discriminate between PD and non-PD individuals. A ROC curve closer to the top-left corner indicates a more effective model, with higher sensitivity and lower false positive rates, whereas a curve closer to the diagonal line signifies a less discriminative model. The area under the ROC curve (AUC) quantifies the overall predictive performance, with a higher AUC indicating better model discrimination. The ROC Curve of PD is essential in evaluating and comparing the performance of predictive models for Parkinson's disease diagnosis and can assist in selecting the most suitable model for clinical or research applications.

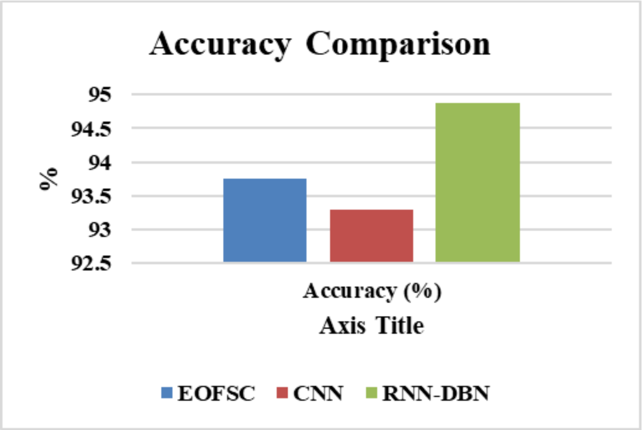

Fig. 8. Comparison of accuracy.

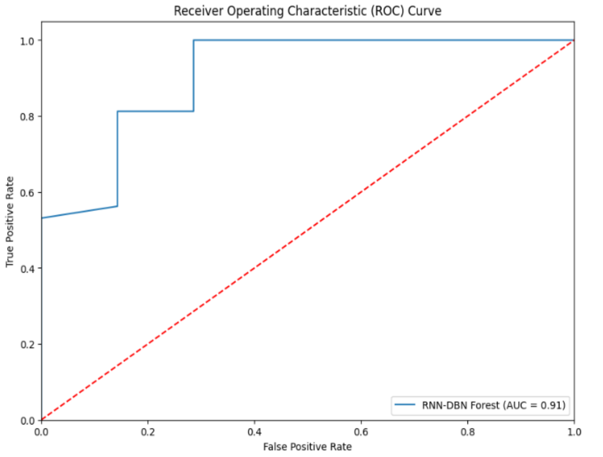

Fig. 9. ROC curve of PD.

VII. CONCLUSION

The incorporation of the RNN-DBN architecture in our research represents a substantial leap forward in the realm of forecasting Parkinson's disease severity. Recognizing the dynamic and sequential nature of medical data, we embarked on this journey to provide more accurate and timely assessments of Parkinson's disease progression. The method's proficiency in identifying patterns and temporal relationships within the data stands out as a key advantage. Recurrent neural networks excel in modeling sequential data, making them an ideal choice for monitoring changes in symptoms and biomarkers over time in Parkinson's patients. The resulting comprehensive predictive model not only delivers precise severity evaluations but also unveils insights into disease progression trajectories by harnessing the synergies between RNNs and the feature extraction capabilities of DBNs. The commitment to data quality and diversity is evident in the utilization of a comprehensive dataset encompassing clinical, demographic, and temporal data points. The RNN-DBN architecture effectively extracts valuable temporal data and patterns, contributing to optimized parameters and enhanced performance, ultimately increasing the model's clinical relevance. With a steadfast focus on ethical considerations and legal compliance, we ensured the proper management of private medical information throughout the research process. Collaboration with medical professionals validated the clinical relevance of our prediction model, underscoring its potential to revolutionize treatment plans and patient care for Parkinson's disease management. This research underscores the substantial promise of the RNN-DBN framework in personalized medicine and disease severity prediction, particularly for conditions like Parkinson's that exhibit temporal variability. However, further validation and refinement are imperative before clinical implementation. We anticipate that our exploration into cutting-edge RNN-DBN algorithms will inspire further studies across diverse medical domains, ultimately advancing patient outcomes and improving quality of life through the intersection of machine learning and healthcare.

VIII. FUTURE SCOPE

Future work in the domain of predicting Parkinson's disease could explore several promising avenues for further research. Firstly, investigating the integration of multimodal data sources, such as combining audio signals with clinical assessments or genetic markers, could enhance the predictive accuracy of the models. Additionally, exploring advanced machine learning techniques, including deep learning architectures like convolutional neural networks (CNNs) or attention mechanisms, may uncover novel insights and improve model performance. Furthermore, conducting longitudinal studies to track disease progression over time and incorporating longitudinal data into predictive models could enable early detection and personalized treatment strategies. Additionally, expanding the scope of the research to encompass other neurodegenerative disorders and exploring shared underlying mechanisms could lead to broader insights and more generalizable predictive models. Lastly, addressing the interpretability of predictive models and developing explainable AI techniques would enhance their utility in clinical practice, facilitating informed decision-making by healthcare professionals. Overall, these future research directions hold promise for advancing our understanding of Parkinson's disease prediction and improving patient outcomes through early intervention and targeted therapies.

Efficiency of Hybrid Decision Tree Algorithms in Evaluating the Academic Performance of Students

Yanxin Xie
Electrical and Information Engineering College, Jilin Agricultural Science and Technology College, Jilin 132101, Jilin, China

***Abstract*—Educational institutions are anticipated to take substantial and proactive roles in guaranteeing students' successful program completion. Academic performance is conventionally employed to categorize and forecast students' future ability to confront post-graduation challenges. A student's academic accomplishments are instrumental in shaping exceptional individuals who may become future leaders. Using algorithms to assess and predict academic performance is a well-established practice in machine learning, encompassing techniques such as neural networks(NN), logistic regression(LR), decision trees(DT), and others. The goal of this project is to improve decision trees' ability to predict students' academic achievement via the use of data mining methods and meta-heuristic algorithms. Educational data mining involves the utilization of data analysis methodologies and tools to examine the extensive data generated within educational establishments as a result of students' interactions and activities throughout their academic journey. Pelican Optimization Algorithm (POA) and Runge Kutta optimization (RKO) are utilized algorithms in developing hybrid models, both of which can efficiently search for optimal or near-optimal splits by fine-tuning the hyperparameters of decision tree models. Students' final grades were predicted through training and testing models and categorized into four classes: Excellent, Good, Acceptable, and Poor. The classification capability of a single model and optimized counterparts was evaluated using Accuracy, Recall, Precision, and F1-score in separate phases for each category. Obtained results for all models revealed that POA and RKO developed Accuracy of DTC by 1.86% and 0.87%. Also, Precision and Recall metric analysis further manifest the superiority of DTPO. Prediction based on classifiers, especially workable optimized versions such as DTPO, paves the way for institutions to raise student success rates.**

***Keywords*—Academic performance; decision tree; pelican optimization algorithm; runge kutta optimization**

I. Introduction

Students' academic success is a fundamental educational objective, representing a key facet of any nation's educational goals. This focus on quality education as a catalyst for social change compels educational institutions to prioritize the nurturing of students who excel in academic and nonacademic assessments and acquire essential practical skills for competitiveness in the labor market. Education is at the heart of societal development, embodying collective aspirations for well-being and progress [1]. The quality of students produced by schools has thus become a prevailing concern. As highlighted by Kriegbaum et al. [2], academic achievement takes center stage, a barometer of intellectual education and a crucial prerequisite for individual and societal prosperity. In this context, Martín [3] emphasizes that academic performance extends beyond intellectual quotient (IQ), encompassing various dimensions to capture students' development's cognitive, psychomotor, and affective domains.

The primary benefit of data mining lies in its ability to thoroughly examine extensive data sets and derive rules that can capture the attention of relevant stakeholders. Furthermore, it can reveal previously undiscovered and valuable insights that greatly aid decision-making. Machine learning (ML) algorithms, specifically renowned for their effectiveness in classification tasks, are a central point of interest in numerous research endeavors [4], [5], [6]. According to Sharma, Himani, and Kumar [7], decision tree algorithms are widely recognized as effective tools for classification. Decision trees (DT) are structured models with root nodes, branches, and leaf nodes for predicting outcomes. These trees can handle numerical and categorical data, are easily understood, and are visually representable. They play a key role in identifying group characteristics and exploring relationships between variables and can be applied to predict student performance and other educational outcomes. Jorda and Raqueno [8] highlight various DT algorithms like C&R Tree, CHAID, C 5.0, and QUEST, which aid in developing classification systems.

II. Related Works Review

Numerous scholars have comprehensively investigated the multifaceted factors influencing student success across various academic levels. Several of these studies have utilized data mining (DM) techniques, particularly classification algorithms, to enhance the quality of higher education systems and predict student performance. In this section, a number of the related studies, especially those focusing on the application of the DT and classification in estimating the academic performance of the students, are presented [9], [10], [11], [12], [13], [14], [15], [16], [17], [18], [19], [20], [21], [22], [23], [24], [25], [26], [27], [28], [29], [30], [31]. For instance, Qasem, Emad, and Mustafa [32] employed the CRISP framework to evaluate students' data in C++ courses, comparing classifiers such as $3, C4.5$ DT, and Naive Bayes (NB). The C4.5 DT outperformed other classifiers, shedding light on the attributes affecting student performance. Another study proposed a DT classification model to select suitable academic tracks for students, facilitating school management's decisions [33]. Nguyen and Peter [34] explored the efficiency of DT and Bayesian networks in predicting undergraduate and postgraduate student performance, revealing the superiority of DTs. Sunita and LOBO LMRJ [35] demonstrated the applicability of DM in education by using classification and clustering algorithms to predict student performance and group students. R. R. Kabra and Bichkar [36] developed classification models to identify at-risk students among first-year engineering students. S. Anupama and Vijayalakshmi [37] applied the C4.5 DT algorithm to predict MCA students' pass/fail outcomes, significantly improving results and efficiency compared to the $ID3$ algorithm. Bharadwaj and Pal [38] utilized the $ID3$ DT algorithm to predict student divisions based on various academic indicators. Surjeet and Pal [39] employed various DT algorithms to predict the performance of first-year engineering students, particularly in identifying those likely to fail. Dorina Kabakchieva [40] compared DM algorithms to predict student performance, classifying students as strong or weak, with the neural network achieving high accuracy for the strong class. Shovon and Mahfuza [41] proposed a hybrid approach combining clustering and classification to categorize students into high, medium, and low standards and make informed decisions about their academic performance, ultimately enhancing their final examination results. These studies collectively demonstrate the versatility of DM and classification algorithms in addressing various facets of student performance and academic success, aiding both educators and educational institutions in improving their educational processes and outcomes.

III. Objectives of the Current Work

As stated in the previous section, a few studies investigated the application of various decision tree classification algorithms in evaluating students' performance at different academic levels. There seems to be a significant gap in the literature related to exploiting the optimization capability of meta-heuristic algorithms in enhancing the evaluation performance of classification algorithms such as decision trees. Therefore, the current study employs Pelican and Runge Kutta optimization algorithms to develop hybrid decision tree models (DTPO and DTRK) for students' performance prediction. This innovative approach assists in detecting the optimization performance of presented algorithms in this field by comparing a single decision tree model with optimized versions using classification metrics such as Accuracy, Recall, Precision, and F1-score. In the following sections, the effect of selected input data on the outcome of models and a description of DTC and two optimizers will be presented. Results will be discussed using tables, bar charts, and confusion matrix for numerical and visual comparison between estimation models.

The study aims to enhance the predictive power of decision trees in predicting students' academic performance. This is achieved by introducing meta-heuristic algorithms, specifically the POA and RKO, to optimize decision tree models. The main research contribution lies in strategically employing these advanced algorithms to overcome limitations in conventional decision tree models. By fine-tuning hyperparameters and searching for optimal splits, the approach significantly improves the efficiency and accuracy of academic performance predictions. This contribution not only advances the understanding of ML applications in education but also provides a practical solution for educational institutions seeking to enhance student success rates.

Previous solutions for predicting students' academic success have faced persistent obstacles, necessitating the development of fresh approaches. Frequent deficiencies in previous endeavors encompass:

1) *Restricted predictive precision:* Numerous current models have had difficulties in attaining elevated accuracy while forecasting academic performance, frequently leading to misclassifications or imprecise categorizations of individuals.

2) *Lack of adaptability:* Traditional techniques may not possess the capacity to handle the dynamic nature of educational data effectively. Static models may not efficiently adapt to changes in learning settings, teaching approaches, or student behaviors.

3) *Excessive dependence on traditional methods:* Previous solutions may have mostly depended on conventional machine learning approaches without fully utilizing the capabilities of modern algorithms. This constraint can impede the capacity to capture complex patterns in educational data.

This study presents an innovative method that utilizes meta-heuristic algorithms, namely the POA and RKO. The application of these algorithms overcomes the constraints of conventional approaches by:

1) *Improved model efficiency:* The integration of meta-heuristic algorithms enhances the efficiency of the decision tree model, resulting in enhanced accuracy in forecasting students' academic achievement. The hybrid models created with the combination of POA and RKO exhibit an improved capacity to adjust to the changing characteristics of educational data, resulting in a more resilient and precise prediction mechanism.

2) *Optimized hyperparameter tuning:* By utilizing the techniques of POA and RKO, the hyperparameters of DT may fine-tune. This allows for a more detailed exploration of the feature space, resulting in better model performance compared to traditional decision tree models.

The overall organization of study in the next sections is as follows:

1) *Dataset selection and preparation:* This section outlines the process of selecting and preparing the dataset for analysis. It discusses the sources of data, data cleaning procedures, and any preprocessing steps applied to ensure the dataset's suitability for the study.

2) *Decision tree and classification:* Here, the focus is on explaining the decision tree algorithm and its application in classifying students' academic performance. It covers the fundamental principles of decision trees, including tree construction, node splitting criteria, and handling categorical and continuous variables.

3) *Optimization algorithms:* This section elaborates on the POA and RKO employed to enhance DT efficiency. It details the implementation of these algorithms to improve predictive accuracy.

4) Performance evaluation metrics: The performance evaluation metrics section discusses the metrics used to assess the effectiveness of the proposed approach. It provides insights into how accuracy, recall, precision, and F1-score are calculated and interpreted in the context of predicting students' academic performance.

5) Result: This section presents the results obtained from applying the proposed methodology to the dataset. It includes tables, graphs, or other visual aids to showcase the performance of the DT models with and without optimization algorithms.

6) Discussion: Here, the results are analyzed and interpreted in-depth. The discussion section delves into the implications of the findings and the limitations.

7) Conclusion: Finally, the conclusion section summarizes the key findings of the study and their implications for predicting students' academic performance. It reiterates the significance of the proposed approach and discusses its contributions to the field.

Fig. 1 shows the process of present study.

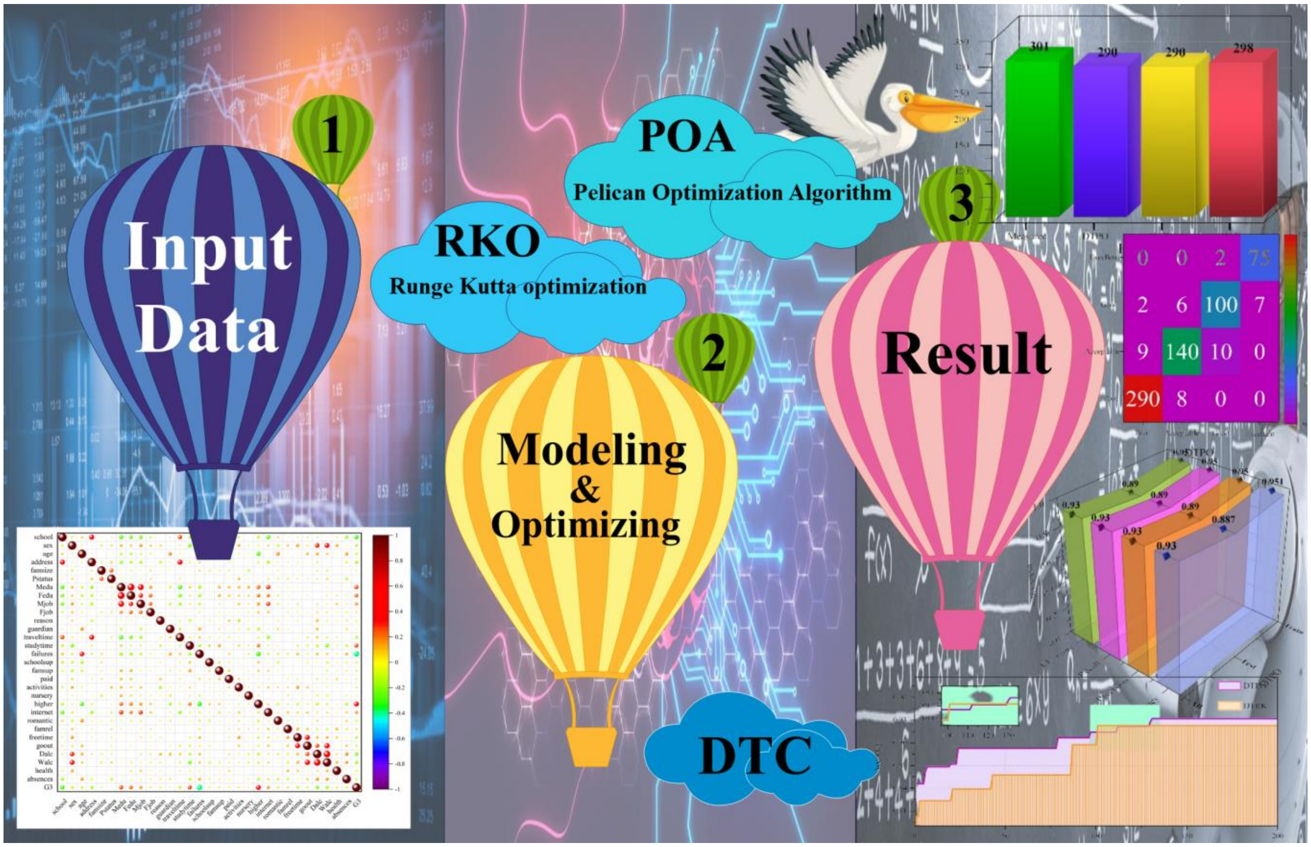

Fig. 1. Process of present study.

IV. Data Selection and Preparation

Data mining, also called database knowledge discovery, entails extracting valuable information from extensive datasets. This process employs various techniques to scrutinize vast data collections, uncovering concealed patterns and relationships that can potentially inform decision-making.

This study utilizes a comprehensive database of variables, which has been gathered from previous research articles. Included in the dataset are facts on the student's school, gender (male or female), age, domicile (rural or urban), family size (famsize), parental cohabitation status (Pstatus), and the mother's and father's educational background and employment (Medu, Fedu, Mjob, and Fjob). It also discusses the student's guardian (father, mother, or other), the reasons for choosing the school (such as proximity to home, school reputation, course preference, or others), the amount of previous class failures, participation in extracurricular activities and paid classes, attendance at nursery school, aspirations for higher education, availability of internet access at home, involvement in romantic relationships, the quality of family relationships (famrel), free time after school, socializing with friends (goout), weekday and weekend alcohol consumption (Dalc and Walc), current health status, and the A wealth of data for the research is provided by these input variables, which include a range of data kinds such as nominal, numeric, and binary. G3, which goes from 0, the lowest possible grade, to twenty, the best possible grade, indicates the final grades that pupils get according to the school. Students are placed into four different groups according to their G3 scores in order to further define and categorize the reported grades: G3 ranges for poor (range of 0– 12), acceptable (range of 12– 14), good (range of 14– 16), and excellent (range of 16– 20) are all available.

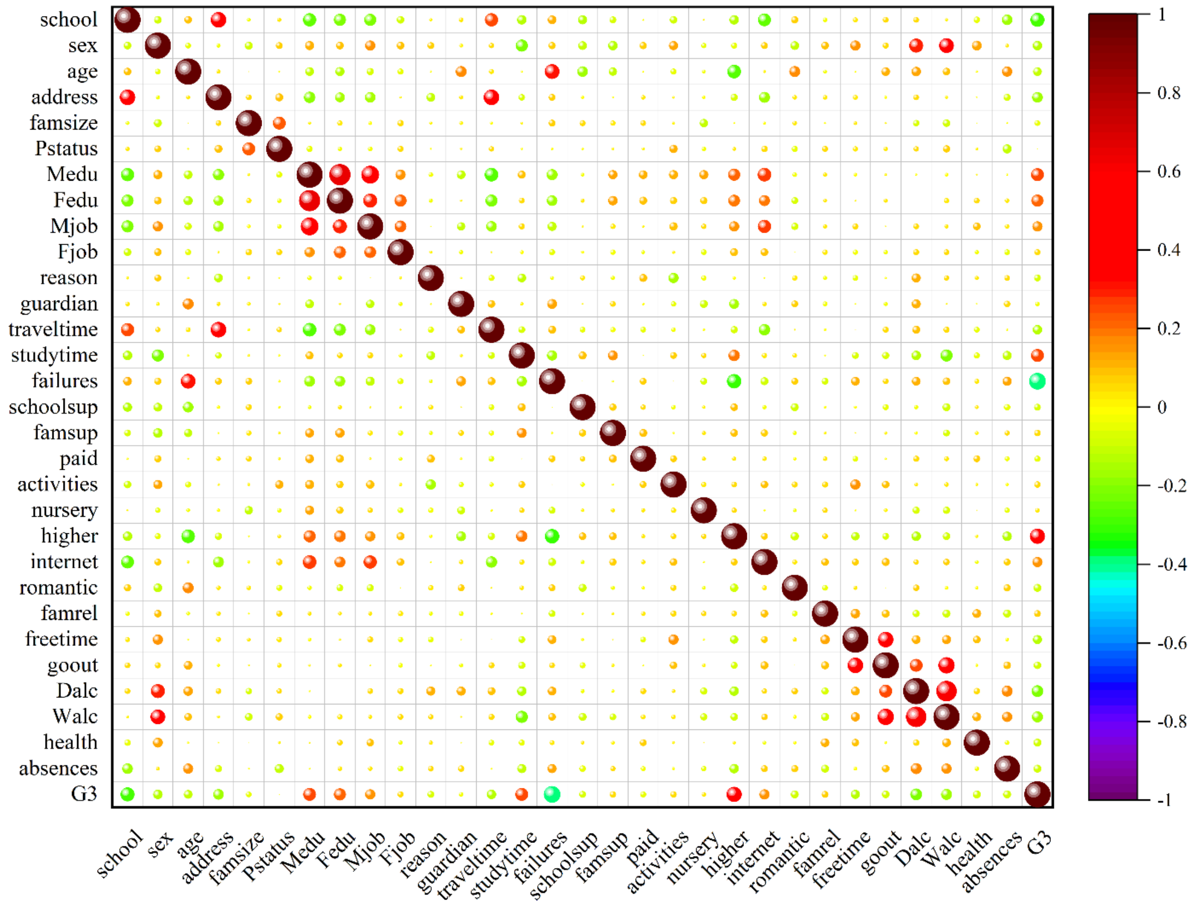

Fig. 2. Correlation matrix for the input and output variables.

In Fig. 2, the correlation matrix illustrates the relationships among all the input and output variables under examination. Parental education has the most substantial positive influence on a student's final grade, with the mother's education exerting a more pronounced effect than the father's. As anticipated, increased study time is positively associated with better academic outcomes, while the number of past failures by a student negatively impacts their grades. The presence of internet access and a student's aspiration for higher education both positively contribute to academic performance, while the adverse effects of alcohol consumption are evident. The most important variables affecting the quantity of absences from school were found to be daily and weekly alcohol intake, past failures, and student age.

V. Decision Tree and Classification

In a DT, which is shaped like a tree and looks like a flowchart, each internal node represents a test that is based on an attribute, each branch denotes the result of that test, and each leaf node also called a terminal node represents a particular class label. In order to use a DT for prediction, a route from the tree's root to a leaf node which holds the predicted class label for that data point is used to evaluate the attribute values of a particular data point ($tuple$). A benefit of decision trees is their ease of conversion into categorization rules. In DT learning, they function as predictive models that allow observations about an item to be translated into judgments about its desired value. Classification trees are a particular kind of these models that handle finite class values, and they are used in statistics, data mining, and machine learning. When compared to other categorization techniques, DT creation is often thought to be a speedy procedure [42].

The DT operates with three crucial parameters:

1) D (Data Partition): The first dataset, denoted by D, consists of training instances and the class labels that go with them.

2) Attribute list: In essence, this parameter is a set of properties that characterize the characteristics of the data.

3) Attribute selection method: The method for selecting the best suitable attribute to form branches or divisions in the decision tree is specified by this option. This usually entails using an attribute selection metric such as the Gini index or knowledge gain.

This is an explanation of the algorithm's operation:

- It starts by creating a node, which can be called "A".
- Should every example in the present dataset belong to the same class, "A" will be designated as a leaf node and assigned the common class label.

- Node "A" is once again designated as a leaf node and given the class that occurs most often in the data samples when the attribute list is empty.
- Next, the algorithm determines which characteristic will be used to divide the data into the cleanest subsets possible.
- This chosen property is given to Node "A" as the decision criteria.
- The selected attribute is eliminated from the list of characteristics if it is discrete.
- Based on the results of the chosen property, subsets of the data are created.
- A leaf node is connected to node "A" and labeled with the majority class of the original dataset if any of these subsets are empty.
- The procedure is repeated recursively for non-empty subsets, beginning with the creation of a new node, and the method continues until all data partitions have been handled.
- The method finally yields the decision tree structure that results.

This approach is a basic procedure for creating decision trees and is often used to data analysis and machine learning applications requiring data categorization and predictive modeling.

VI. Optimization Algorithms

A. Pelican Optimization Algorithm (POA)

Dehghani and Trojovský [43] introduced a novel metaheuristic optimization method, the POA , to address optimization issues based on swarm intelligence. The hunting habits of pelicans, who often hunt in groups and display a variety of clever tactics, served as the model for the algorithm. As an example, pelicans identify their prey's location ahead of time and move quickly to get close to it. They then hunt by swatting at a distance of 10 to 20 meters. The phases in the POA algorithm provide a comprehensive structure [44].

1) Initialization of the population: Usually, pelicans look for food in a specific area of the search habitat. As a result, each pelican inside this range is randomly assigned a starting location by the POA algorithm, which therefore initializes the population. A random number generator is used for this random initialization, which gives the pelicans their starting places.

$$P_i = S_{min} + rand.(S_{max} - S_{min}) \quad i = 1, \dots, I \tag{1}$$

Here, P_i signifies the original spatial location of the $i-th$ one in the populace. The maximum number of pelicans in the population is indicated by parameter I. The search space's exploration area's $lower$ and $upper$ bounds are defined, respectively, by the variables $Smin$ and $Smax$. Every pelican in the designated search area is given a random location based on a random integer generated by the function $rand\ \cdot ()$.

2) Exploration phase: The pelicans' main goal at this point is to discover and pinpoint the location of their prey while simultaneously changing postures in anticipation of an assault. In order to do this, each pelican in the population has its geographic coordinates updated using Eq. (2):

$$P^1_{i,j} = \begin{cases} P_{i,j} + rand.\left(P_{pj} - U.P_{i,j}\right), & f_p < f_i \\ P_{i,j} + rand.\left(P_{i,j} - P_{pj}\right), & else \end{cases} \tag{2}$$

Here, P^1_{ij} represents the updated position of the $i-th$ pelican in the $j-th$ dimension, while P_{pj} represents the position of the prey. The prey's and the pelican's performance measures are shown by f_p and f_i, respectively. The update equation that is used to modify the pelican's location is determined by the parameter U, which is a random integer that may have a value of either 1 or 2.

3) Exploitation phase: The pelicans are ready to attack at this point as they have found their victim. The pelicans use acrobatic manoeuvres above the water as part of their predatory strategy to force the fish into their throat pouches. The following is a mathematical representation of this strategy:

$$P^2_{i,j} = P_{i,j} + z.\left(1 - \frac{t}{T}\right).(2.rand - 1).P_{i,j} \tag{3}$$

Here, $P^2_{i,j}$ signifies the $j-th$ dimension's revised position for the $i-th$ one. The pelican's location is changed throughout exploitation by adjusting the parameter z, which is a random integer that might have a value of 0 or 2. T stands for both the current iteration of the algorithm and the maximum number of iterations.

The following pseudo-code contains the full statement of the POA algorithm:

```
Start POA
Input the optimization problem information.
Determine the POA population size $(N)$ and the number of iterations $(T$
Initialization of the position of pelicans and calculation of the objecti
For $t = 1{:}T$
Generate the position of the prey at random.
For $I = 1{:}N$
Phase 1: Moving towards prey (exploration phase).
For $j = 1{:}m$
Calculate the new status of the jth dimension using Eq. (2).
End.
Update the ith population member.
Phase 2: Winging on the water surface (exploitation phase).
For $j = 1{:}m$.
Calculate the new status of the jth dimension using Eq. (3).
End.
Update the ith population member.
End.
Update best candidate solution.
End.
Output best candidate solution obtained by POA.
End POA.
```

B. Runge-Kutta Optimization (RUN)

Ahmadianfar et al. introduced the Runge-Kutta optimizer (RUN) [45], a population-based algorithm inspired by the

Runge-Kutta method for solving differential equations. RUN comprise two main stages: an initial search procedure influenced by Runge−Kutta principles and a subsequent phase called enhanced solution quality (ESQ) to improve solution quality. This study details the core principles supporting the RUN algorithm.

1) First stage: The algorithm of RUN utilizes a search mechanism (SM) that depends on the Runge-Kutta method to update the current solution's position in each iteration.

Algorithm 1: The RUN algorithm employs a SM to update the present solution's position.

```
$if\ rand\ <\ 0.5\ then$
$(exploration\ phase)$
$X_{\ n+1} = (X_c + r \times SF \times g \times x_c)\ + SF \times SM + \mu\ \times (randn\ \times\ (x_m - x_c))$
$else$
$(exploration\ phase)$
$X_{\ n+1} = (X_m + r \times SF \times g \times x_m) + SF \times SM + \mu\ \times (randn \times (x_{r1} - x_{r2}))$
$end\ if$
```

m indicates a random numerical value. g is allocated a stochastic value within the range of [0, 2]. r is a numeric value, which can take on either 1 or -1, which serves to increase the diversity within the range.

The determination of the adaptive factor SF involves calculations that include Eq. (4):

$$SF = 2 \times (0.5 - rand) \times f \tag{4}$$

$$F = a \times exp(-b \times rand \times (\frac{i}{Max_i})) \tag{5}$$

Max_i denotes the upper limit for the number of iterations.

x_c and x_m is computed through the utilization of Eq. (6) and Eq. (7):

$$x_c = \emptyset \times x_n + (1 - \emptyset) \times x_{r1} \tag{6}$$

$$x_m = \emptyset \times x_{best} + (1 - \emptyset) \times x_{lbest} \tag{7}$$

x_{best} represents the currently best available solution. x_{lbest} denotes the optimal position achieved during each iteration. f indicates a random value within the interval of (0, 1).

2) Second stage: To enhance solution quality and mitigate the risk of becoming stuck in local optima during each iteration, the RUN algorithm employs a technique referred to as Enhanced Solution Quality (ESQ).

Algorithm 2 delineates the steps involved in generating the solution (x_{new2}) through ESQ.

Algorithm 2: mathematical presentation of the second stage

```
if $rand < 0.5$ then
if $w < 1$ then
          $x_{new2}\ =\ x_{new1}\ +\ r.w.\left|(x_{new1}\ -\ x_{avg}\ )\ +\ randn\right|$
else
    $x_{new2}\ =\ (x_{new1}\ -\ x_{avg}\ ) +\ r.w.\left|(u.x_{new1}\ -\ x_{avg}\ )\ +\ randn\right|$
end if
end if
```

$$w = rand(0,2).exp(-c(\frac{t}{Max_i})), \quad c = 5 \times rand \tag{8}$$

$$x_{avg} = \frac{x_{r1} + x_{r2} + x_{r3}}{3} \tag{9}$$

$$x_{new1} = \beta \times x_{avg} + (1 - \beta) \times x_{best} \tag{10}$$

b denotes a number generated at random within the range of [0,1].

x_{best} denotes the best solution identified up to the current stage of exploration. r can take on any of the following values: 1.0 or -1. $rand$ indicates a parameter that is generated randomly.

The answer x_{new2} might not consistently exhibit better fitness when compared to existing solutions under these circumstances, the RUN algorithm presents an additional opportunity to boost fitness through utilization x_{new3} . Algorithm 3 outlines the procedure's sequential steps.

Algorithm 3: Improving the novel solution xnew3

```
if $rand\ <\ w$ then
    $x_{new3} = (x_{new2} - rand x_{new2}) + SF.(rand.x_{RK} + (v.x_b - x_{new2}))$
end if
```

v is randomly generated and equals double the value of $rand$.

Algorithm 4 offers the pseudo-code for the main stages of the RUN optimization procedure.

Algorithm 4: Pseudo-Code of RUN Optimization

```
$Stage\ 1. Initialization$
$Start\ a, b$
$Create\ the\ RUN\ population\ X_n\ (n = 1,2,\ldots, N)$
$Compute\ the\ objective\ function\ of\ each\ member\ of\ the\ population$
$Determine\ the\ solutions\ x_w, x_b, and\ x_{best}$
$Stage\ 2. RUN\ operators$
$for\ i\ = 1:\ Maxi\ do$
$for\ n\ = 1:\ N\ do$
$for\ l\ = 1:\ D\ do$
$Updating\ solutions$
$Compute\ position\ x_{n+1,l}$
$end\ for$
$Enhance\ the\ solution\ quality$
$if\ rand\ < 0.5\ then$
$Compute\ position\ x_{new2}$
$if\ f(x_n) < f(x_{new2})\ then$
$if\ rand\ < w\ then$
$Compute\ position\ x_{new3}$
$end\ if$
$end\ if$
$end\ if$
$Update\ positions\ x_w\ and\ x_b$
$end\ for$
$Update\ positions\ x_{best}$
$i\ =\ i\ +\ 1$
$end\ for$
$Stage\ 3. return\ x_{best}$
```

VII. Performance Evaluation Metrics

In this section, the effectiveness of the proposed approach and models is systematically assessed by employing a set of well-established performance evaluation metrics. These metrics serve as quantitative measures to gauge the accuracy, precision, recall, and overall efficacy of the decision tree models, particularly those optimized using the POA and RKO.

The accuracy of the model is determined by dividing the number of accurately predicted occurrences by the total number of instances. It offers a broad summary of the model's performance in producing precise classifications for every class.

Precision measures the proportion of accurately anticipated positive occurrences to all expected positive instances, with an emphasis on the accuracy of positive forecasts. The model's capacity to reduce false positives is shown by a high accuracy score.

The capacity of the model to accurately identify all relevant occurrences is measured by recall, which is sometimes referred to as sensitivity or true positive rate. The ratio of accurately anticipated positive cases to the total number of actual positive instances is used to compute it.

The F1-score is the harmonic mean of precision and recall. It provides a balanced measure, especially in situations where there is an imbalance between the classes. A higher F1-score indicates a model that performs well in both precision and recall.

Statistical metrics for evaluating the classification capability of developed models are presented as follows:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{11}$$

$$Precision = \frac{TP}{TP + FP} \tag{12}$$

$$Recall = TPR = \frac{TP}{P} = \frac{TP}{TP + FN} \tag{13}$$

$$F1\_score \ = \frac{2 \times Recall \ \times \ Precision}{Recall + Precision} \tag{14}$$

where,

- TP (True positives): the instances where the model's predictions were accurate.
- TN (True negatives): the instances that were correctly predicted.
- FP (False positives): the instances that were inaccurately forecasted
- FN (False negatives): the instances that were wrongly predicted.

VIII. Convergence Assessment

Throughout this investigation, we employed two metaheuristic optimization algorithms, namely the POA and RKO, to augment the DTC, leading to the development of hybrid models denominated as DTPO and DTRK. A thorough examination of the convergence dynamics of these optimized models was conducted, utilizing a convergence curve illustrated in Fig. 3.

The convergence curve, derived from Accuracy measurements spanning 200 iterations, serves as an instructive visual representation of the optimization procedure. Fig. 3 distinctly delineates the convergence trajectories of DTRK and DTPO. Noteworthy is the similarity in convergence rates exhibited by both models, particularly up to the midpoint of the optimization process.

At approximately the 115th iteration, DTRK and DTPO achieved a comparable peak Accuracy, both recording an impressive 0.92. However, as the iterations progressed, an intriguing divergence in their convergence patterns surfaced. DTRK showcased exceptional stability, sustaining its peak accuracy throughout the remaining iterations. Conversely, DTPO experienced a substantial surge in accuracy around the 130th iteration, ultimately surpassing DTRK in the final phases of the optimization process.

These subtle fluctuations in convergence behavior provide insights into the dynamic nature of the optimization algorithms and their influence on the performance of the hybrid models. The observed intricacies underscore the delicate interplay between the metaheuristic algorithms, DT optimization, and resulting accuracy levels. This nuanced analysis offers valuable perspectives on the strengths and limitations inherent in each approach throughout the iterative optimization process.

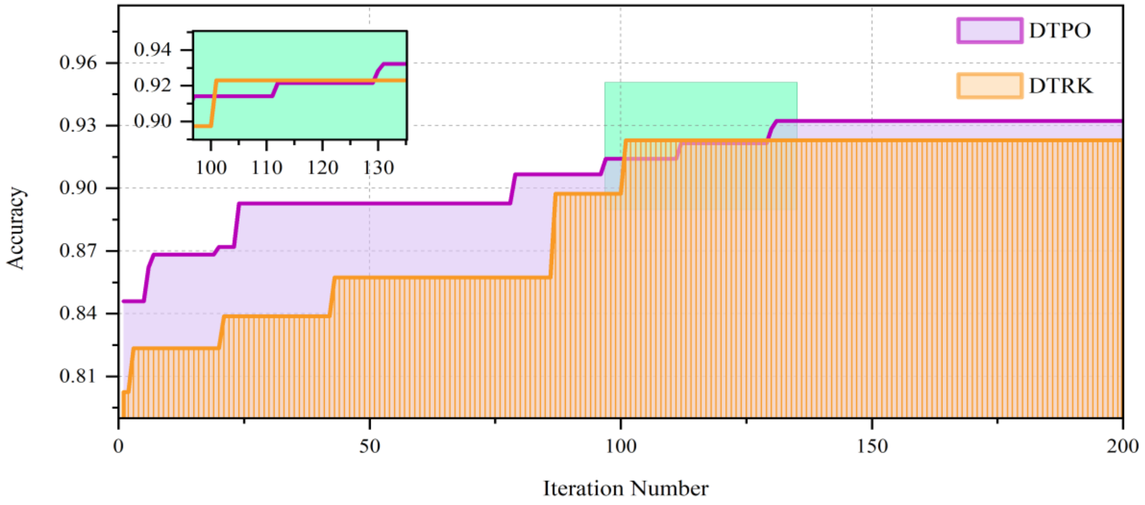

Fig. 3. Convergence of hybrid models.

IX. Results

With the purpose of predicting students' academic performance and methodically improving their future grades, this research presented three prediction models that use a categorization methodology. Table I shows the results of presented models. One of these models was a Decision Tree Classifier (DTC), while the other two were created by using Runge Kutta optimization (RKO) and the Pelican Optimization Algorithm (POA) to optimize the DTC. A portion of the dataset 70% for train and 30% for test the model was kept aside. For each model, training and testing stages provide metrics like accuracy, precision, recall, and F1-score; all results are shown in Fig. 4. Metric values were notably higher for all models during the train period than during the test phase. DTPO achieved the highest values across all metrics ($Accuracy = 0.932$, $Precision = 0.930$, $Recall = 0.930$, and $F1 - score = 0.930$), while DTC scored lower by approximately 1%. DTRK, in most cases, has metrics values slightly higher than the single model or the same values.

TABLE I. Result of Presented Models

Model	Phase	$Index\ values$			
		$Accuracy$	$Precision$	$Recall$	$F1\ \_score$
DTC	$Train$	0.915	0.910	0.910	0.910
	$Test$	0.892	0.890	0.890	0.890
	All	0.915	0.920	0.920	0.910
DTPO	$Train$	0.952	0.950	0.950	0.950
	$Test$	0.887	0.890	0.890	0.890
	All	0.932	0.930	0.930	0.930
DTRK	$Train$	0.923	0.920	0.920	0.920
	$Test$	0.903	0.900	0.900	0.900
	All	0.923	0.920	0.920	0.920

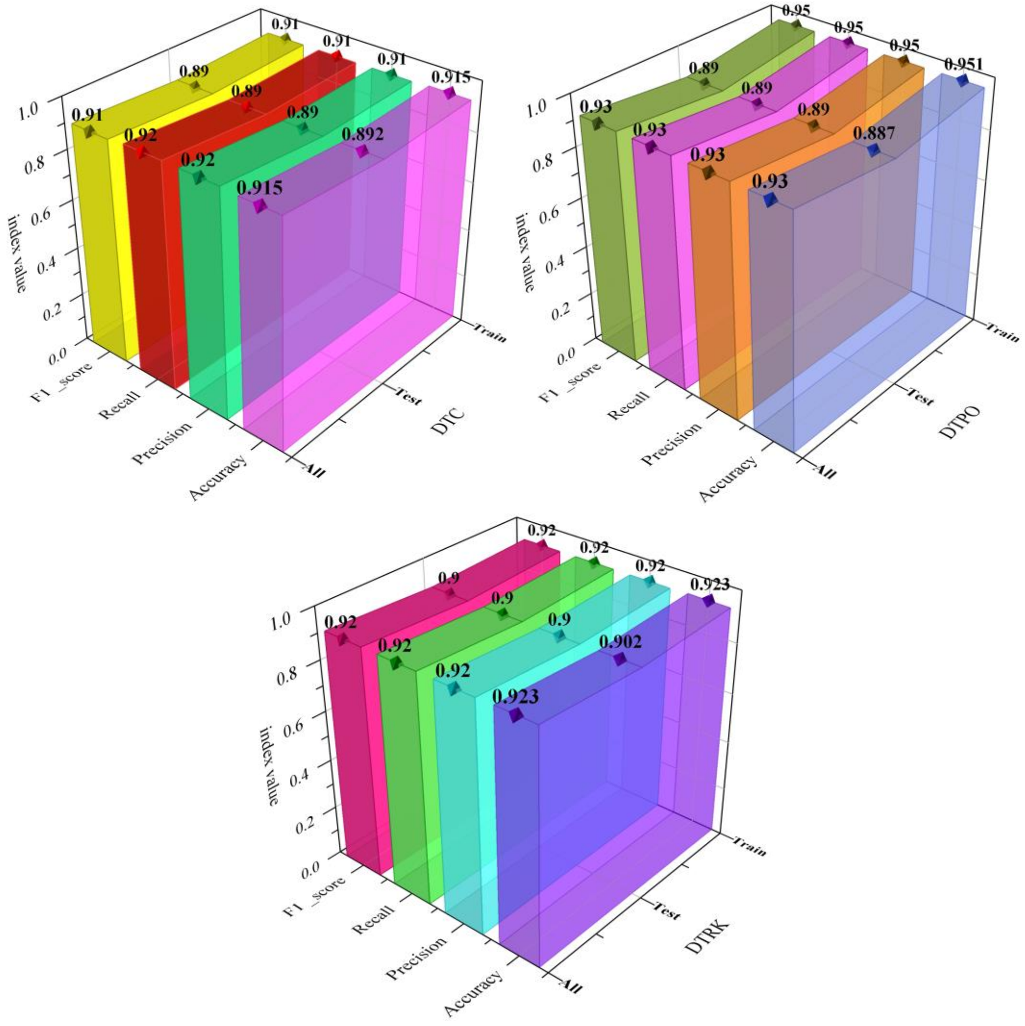

Fig. 4. Metrics performance of developed models.

After processing the data and evaluating the models' classification performance in both training and testing phases, the 649 pupils' $G3$ test scores were used to divide them into four groups: Poor (G3: 0-12), Acceptable (G3: 12-14), Good (G3: 14-16), and Excellent (G3: 16-20). The distribution revealed that the majority of students (46.38%) fell into the Poor category, with 23.73% in Acceptable, 17.26% in Good, and 12.63% in excellent categories.

To evaluate how well the created models performed in terms of categorization across various student groups, Table II shows the values for the Precision, Recall, and F1-score indices. In the analysis that follows:

- Comparing Precision values, in the excellent group, DTC and DTPO had an identical performance with 0.97, while DTRC was less precise with 0.95. In the Good and Poor groups, DTPO outperformed two other models, and finally, in the Acceptable group, the DTC single model performed superior to others. Considering all these results, it is not possible to introduce an absolute optimal model based on the Precision metric.
- Variation of the Recall metric was the same as Precision. All models performed better in the Poor category, with higher recall values of 0.96 for optimized versions and 0.99 for single models.
- The F1-score, a comprehensive metric, provides a nuanced basis for comparison. Higher F1-scores (nearest to 1) indicate superior model performance by balancing accurate identification of positive cases ($Precision$) and capturing all genuine positive cases ($Recall$). Across all student grades, DTPO demonstrated the highest accuracy with F1-scores of 0.94, 0.88, 0.89, and 0.97 for Excellent, Good, Acceptable, and Poor students, respectively. So, based on F1-score, DTPO came in the first ranking, followed by DTRK and DTC.

According to Fig. 5, there were really $301, 154, 112$, and 82 pupils in the Poor, Acceptable, Good, and Excellent categories. The frequency of students in each category based on classification models' outcomes is illustrated in the form of a bar chart for visual comparison. Comparing the two optimized models, they perform similar performance in Poor and Good classes, with 290 and 100 students correctly positioned in this group, but in two other groups, DTPO correctly classified three students higher than DTRK. The classification performance of the single model in the Poor and Good classes is better than hybrid models, especially in the Poor category. However, in Acceptable and Excellent groups, DTC succeeds inappropriately classifying a lower number of students than hybrid versions.

The confusion matrix presented in Fig. 6 clearly represents the accurate assignment of students to their respective grade categories and those who were misclassified. The numbers in diagonal raw represent the number of successfully organized models, and all numbers out of these squares are related to incorrect classification. For the DTPO model, 605 students were correctly categorized into Excellent, Good, Acceptable, and Poor classes, with only 44 misclassified. In the case of DTRK and DTC, 50 and 55 students were misclassified. The highest value of misclassification occurred in the case of DTC (20 students). Therefore, DTPO and DTC were the best and worst models for estimating students' academic performance.

TABLE II. PERFORMANCE EVALUATION INDICES FOR THE DEVELOPED MODELS BASED ON GRADES

Model	Grade	$Index\ values$		
		$Precision$	$Recall$	$F1-score$
DTC	$Excellent$	0.970	0.830	0.890
	$Good$	0.820	0.900	0.860
	$Acceptable$	0.950	0.820	0.880
	$Poor$	0.930	0.990	0.960
DTPO	$Excellent$	0.97	0.91	0.94
	$Good$	0.87	0.89	0.88
	$Acceptable$	0.88	0.91	0.89
	$Poor$	0.97	0.96	0.97
DTRK	$Excellent$	0.95	0.88	0.91
	$Good$	0.85	0.89	0.87
	$Acceptable$	0.91	0.89	0.9
	$Poor$	0.95	0.96	0.96

X. Discussion

A. Limitations

Ensuring data quality is vital for accurate predictive models, necessitating thorough preprocessing to address issues like missing values. Generalizing findings to diverse settings requires additional validation, emphasizing collaborations and diverse datasets. Meta-heuristic algorithm sensitivity underscores the importance of exploring robustness under varied conditions and conducting stability analyses. While these algorithms enhance accuracy, their reduced interpretability can be addressed through interpretable techniques, promoting transparency and trust in educational settings. Addressing data quality, generalizability, algorithm sensitivity, and interpretability collectively contributes to reliable, applicable, and transparent predictive models, facilitating improvements in student outcomes and educational practices.

B. Application of Study

The study's application in education encompasses the implementation of optimized decision tree models using meta-heuristic algorithms. These models facilitate early intervention for at-risk students, personalized learning plans, and strategic resource allocation. Insights from the study inform curriculum adaptation, student guidance, and institutional planning. The continuous improvement aspect involves refining models based on comparative analyses, while metrics evaluation ensures quality assurance. Overall, the study's practical implications extend to various facets of education, contributing to enhanced student success and institutional effectiveness.

XI. Conclusion

In pursuing academic excellence and improving education, this research underscores the pivotal role of data mining and classification algorithms, particularly decision tree models, in understanding and predicting student performance. It builds on a substantial body of related studies by introducing an innovative approach that leverages meta-heuristic optimization algorithms, specifically the Pelican and Runge Kutta optimizers (RKO and POA), to enhance the precision and accuracy of student performance models. The comprehensive evaluation employing key metrics like Accuracy, Precision, Recall, and F1-score highlights the potential of these meta-heuristic algorithms in optimizing classification outcomes. RKO enhanced the Accuracy and Precision of DTC by about 1 to 2 percent. POA performed weaker with the same Precision as DTC and lower than 1% enhancement in Accuracy. Furthermore, the categorization of 649 students based on their final grades revealed the superior performance of the DTPO in enhancing classification accuracy as it demonstrated a remarkable ability to correctly classify the majority of students (605 out of 649), while DTRK and DTC had more false classifications. This study not only added to the existing knowledge in the field but also provided valuable insights for educators and institutions striving to enhance educational processes and foster academic success, thus contributing to the broader goal of societal development and progress. Future studies should focus on improving the validity and real-world applicability of proposed predictive models for academic performance. This includes validating models across diverse educational institutions, assessing their long-term predictive power post-graduation, and conducting a thorough analysis of feature importance to guide targeted interventions. Exploring techniques for enhancing model interpretability without sacrificing accuracy is crucial for building trust among stakeholders. Additionally, comparative analyses with other advanced machine learning models in educational data mining can offer a comprehensive understanding of the proposed models' effectiveness. These recommendations aim to strengthen the reliability and practical utility of predictive models in predicting academic performance.

A Novel Robust Stacked Broad Learning System for Noisy Data Regression

Kai Zheng[1], Jie Liu[2]
Office of Academic Research, Moutai Institute, Renhuai, China[1]
Department of Brewing Engineering Automation, Moutai Institute, Renhuai, China[2]

***Abstract*—Robust broad learning system (RBLS) demonstrates the generalization and robustness for solving uncertain data regression tasks. To enhance representation ability of RBLS, this paper aims at developing a novel robust stacked broad learning system for solving noisy data regression problems, termed as RSBLS. In our work, we expand traditional BLS into a stacked broad learning system model with deep structure of feature nodes and enhancement nodes. Furthermore, ℓ_1 norm loss function is employed to update the objective function of RSBLS for processing noisy data, we apply augmented Lagrange multiplier (ALM) to get the output weights of RSBLS which keeps the effectiveness and efficiency compared with weighted loss function. Simulation results over some regression datasets with outliers demonstrate that, the proposed RSBLS performs favorably with better robustness with respect to RVFL, BLS, Huber-WBLS, KDE-WBLS and RBLS.**

Keywords—Robust; stacking; broad learning system; deep learning; neural networks

I. Introduction

Recently, inspired by random vector functional link neural networks (RVFL) [1, 2], Chen et al. proposed a novel randomized neural network architecture, broad learning system (BLS) [3-5]. Compared with the classical deep learning model, BLS adopts the broad structure which has the advantages of higher efficiency and fewer parameters. Due to its excellent learning ability, BLS has been widely concerned by scholars since it was proposed, and has developed rapidly in theoretical and applied research. To improve the interpretability of BLS, a novel broad neuro-fuzzy model, fuzzy broad learning system (FBLS) was presented, which reduces the number of fuzzy rules and improves the learning accuracy neuro-fuzzy model [6]. Subsequently, Guo et al. used FBLS to synthesize multi-view HDR images [7], Ali proposed a novel optic disk and cup segmentation method through FBLS for glaucoma screening [8]. Furthermore, compact FBLS (CFBLS) which has better interpretability and fewer fuzzy rules was designed to balance the algorithm accuracy and complexity [9]. For improve the representation of BLS, type-2 fuzzy BLS was given in [10]. For solving sequential data, recurrent broad learning system and structured manifold broad learning system (SM-BLS) were presented respectively [11, 12]. To process the data with less label, semi-supervised broad learning system (SS-BLS) by introducing manifold regularization method to BLS [13], and some other SS-BLS algorithms had been used in semi-supervised classification tasks [14, 15]. Otherwise, BLS and its variants had been extensive used in various engineering fields, such as traffic forecasting [16], image classification [17], EEG signals classification [18-20], sentiment analysis [21, 22].

In practical engineering applications, sensors are susceptible to equipment failure, human interference, working environment and other factors, and there are different degrees of noises and outliers in the collected data, thus reducing the generalization of the learning model. To solve the uncertain data regression problem effectively, Chu et al. proposed weighted broad learning system (WBLS) framework for tackling industrial noisy data [23]. Then, Zheng et al. designed a broad learning system based on maximum correntropy criterion (BLS-MCC) which used maximum correntropy criterion to calculate weights of training samples [24]. In addition, Liu et al. adopted Cauchy loss function to process the noisy data [25]. Meanwhile, ℓ_1 norm cost function and ℓ_2 regularization method were used in robust broad learning system (RBLS) [26], then elastic-net regularization approach replaced ℓ_2 regularization method in RBLS [27]. Moreover, robust manifold broad learning system (RM-BLS) was used to predict large-scale noisy chaotic time series [28]. In addition, for online sequential learning, Guo et al. presented online robust echo state broad learning system (OR-ESBLS) [29]. However, the above models improved the robustness of BLS, the shallow models still lack feature representation capability.

Now-a-days, deep neural networks with multi-layer have powerful representation capability, BLS was also been expanded with multi-layers [30-32]. Therefore, to improve the noisy data processing performance of RBLS, we demonstrate a novel robust stacked broad learning system (RSBLS) for solving outlier data regression, which adopts deep structure of feature nodes and enhancement nodes through stacking deep model, ℓ_1 norm loss function and ℓ_2 regularization method ensure the learning accuracy and efficiency.

In brief, the highlights of RSBLS are listed as follows:

- A novel robust stacked broad learning system structure is demonstrated, we presented the model architecture and algorithm description of RSBLS in detail.
- ℓ_1 norm loss function and ℓ_2 regularization method are adopted to enhance the robustness of RSBLS.
- Experiments on the benchmark datasets with different noise ratios present the superiority of RSBLS.

The other sections of our manuscript are given as follows: Section II introduces the basic algorithm description of BLS. Section III presents the architecture and optimization method of the proposed RSBLS. Section IV demonstrates the uncertain data regression results on some datasets with different percentage of outliers. Finally Section V concludes the paper.

II. Related Works

BLS is novel random neural network model with effective and efficient performance, proposed by Chen et al., which has the architecture as Fig. 1 [3-5].

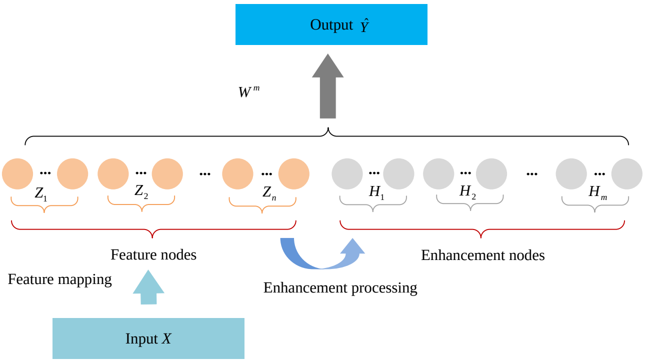

Fig. 1. The structure of BLS [3-5].

The modeling process of BLS is given as follows [3-5]:

Given a training data $\{X,Y\}$, $X=\{x_1,x_2,\ldots,x_N\}$ and $Y=\{y_1,y_2,\ldots,y_N\}$ express the feature and label. Among them, $x_i=\{x_{i,1},x_{i,2},\ldots,x_{i,d}\}\in\square^{d}$, d is denoted as the number of feature dimension; $i=1,2,\ldots,N$, N indicates the number of training samples.

A. Feature Nodes Generation

The feature nodes are generated through Eq. (1), then n groups of mapping nodes can be combined according to Eq. (2), each group has L_e feature nodes.

$$Z_p=\phi(XW_{ep}+\beta_{ep}) \tag{1}$$

$$Z^n=[Z_1,Z_2,\ldots,Z_n] \tag{2}$$

Among them, $\phi(\cdot)$ indicates the activation function of feature mapping; W_{ep} and β_{ep} represent random weights and biases respectively; $p=1,2,\ldots,n$. In particularly, the authors of BLS use sparse autoencoder to tune the initial parameters for obtaining better features [3-5].

B. Enhancement Nodes Generation

All the feature nodes in Eq. (2) are enhanced by using Eq. (3), each enhancement processing generate L_h nodes. Then the enhancement nodes can be combined according to Eq. (4).

$$H_q=\xi(Z^n\mathrm{W}_{hq}+\beta_{hq}) \tag{3}$$

$$H^m=[H_1,H_2,\ldots,H_m] \tag{4}$$

where, $\xi(\cdot)$ is denoted as the activation function, it can be set as the same as $\phi(\cdot)$; W_{hq} and β_{hq} are generated randomly; $q=1,2,\ldots,m$.

C. Output Y determination

The output $\hat{Y}$ of BLS can be calculated according to Eq. (5).

$$Y=[Z^n\,|\,H^m]W \tag{5}$$

$$W=[Z^n\,|\,H^m]^{+}Y \tag{6}$$

where, W represents the output weight of BLS, $[Z^n\,|\,H^m]^{+}$ is determined by the ridge regression approximation as Eq. (7).

$$[Z^n\,|\,H^m]^{+}$$
$$=\lim_{\lambda\to 0}(\lambda I+[Z^n\,|\,H^m][Z^n\,|\,H^m]^T)^{-1}[Z^n\,|\,H^m]^T \tag{7}$$

III. Robust Regularized Hierarchical Broad Learning System

A. The Structure of RSBLS

BLS, as a randomized learning algorithm, has an effective and efficient structure. Although the novel structure can reduce the computational burden and enhance learning accuracy, BLS with multi-layer structure can extract deep representation information [30-33]. Meanwhile, the noisy and outliers in the training data affect the accuracy and generalization performance of BLS seriously. Therefore, we propose a novel RSBLS to solve noisy data regression problems. It is different from traditional BLS, RSBLS has multi-layer structure of feature nodes and enhancement nodes, the feature nodes and enhancement nodes of each layer are used as the input of next layer, only the feature nodes and enhancement nodes of the final layer are fully connected with the output.

In addition, due to the outliers usually take up a fraction of training data, the noisy data can be understood as having sparsity, ℓ_1 norm function is not only more robust to solving the sparsity data, but also ensures a faster learning efficiency, it is especially suitable for solving large-scale data and deep models [34, 35]. The RSBLS adopts ℓ_1 norm cost function and ℓ_2 regularization method to solve the noisy data regression. Fig. 2 demonstrates the model structure of RSBLS; the RSBLS algorithm is described as follows:

1) RSBLS parameters initialization: To simplify the RSBLS model, the layer number is set as U, the feature mapping times of each layer are set to nu, the number of neurons in each feature mapping is L$_{ue}$, the enhancement processing times of each layer are set to mu, and the number of neurons in each enhancement processing is L$_{uh}$.

a) Feature nodes generation: The original data X is transformed into feature nodes by using Eq. (8), then all the nodes in the feature layer are combined through Eq. (9) and Eq. (10).

$$Z_p^u=\phi(X^uW_{ep}+\beta_{ep}) \tag{8}$$

$$Z^u=[Z_1^u,Z_2^u,\ldots,Z_{nu}^u] \tag{9}$$

where, $X^1 = X$; $X^u = S^{u-1}$; $\phi(\cdot)$ indicates the activation function of feature mapping; W_{ep} and β_{ep} are random values of feature nodes; $p = 1, 2, \ldots, nu$; $u = 1, 2, \ldots, U$.

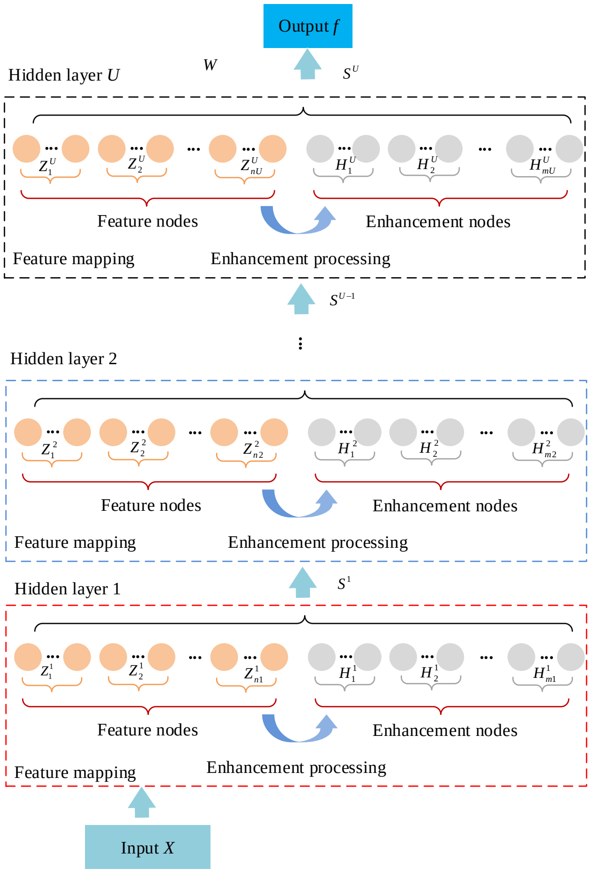

Fig. 2. The structure of RSBLS.

b) Enhancement nodes generation: All the feature nodes in Eq. (9) are enhanced as enhancement nodes through Eq. (10), then all the enhancement nodes are connected by Eq. (11).

$$H_q^u = \xi([Z^u W_{hq} + \beta_{hq}) \qquad (10)$$

$$H^u = [H_1^u, H_2^u, \ldots, H_{mu}^u] \qquad (11)$$

where, $\xi(\cdot)$ expresses the activation function of enhancement processing; W_{hq} and β_{hq} indicate the random parameters of enhancement nodes; $q = 1, 2, \ldots, mu$; $u = 1, 2, \ldots, U$.

In addition, we combine all the nodes of layer *u* through Eq. (12) as the input of next layer.

$$S^u = [Z^u, H^u] \qquad (12)$$

c) Target output matrix Y determination: To reduce the computational burden of RSBLS, we only connect the feature nodes and enhancement nodes of layer U in Eq. (13), then we use the ℓ_1 norm cost function and ℓ_2 regularization method to calculate the model output weights as Eq. (14).

$$S^U = [Z^U, H^U] \qquad (13)$$

$$\beta = \arg\min_{\beta} \| S^U \beta - Y \|_1 + C \| \beta \|_2^2 \qquad (14)$$

where, *C* express as the ℓ_2 regularization parameter.

The outputs of RSBLS can be calculated by Eq. (15).

$$Y = S^U \beta \qquad (15)$$

B. The Optimization of RSBLS

Hence Eq. (14) can be considered as a constrained convex optimization problem, we use augmented Lagrange multiplier (ALM) approach to solve this problem, and Eq. (14) can be transformed as Eq. (16).

$$\begin{aligned} L_\mu(e,\beta,\gamma) &= \| e \|_1 + \frac{1}{C} \| \beta \|_2^2 \\ &+ \upsilon^T (Y - H\beta - e) + \frac{\mu}{2} \| Y - H\beta - e \|_2^2 \end{aligned} \qquad (16)$$

where, $e = \beta H - Y$; υ is denoted as the vector of Lagrange multiplier; $\mu = 2N / \| Y \|_1$.

The optimal (e, β) and the Lagrange multiplier υ can be optimized by ALM method iteratively by using Eq. (17).

$$\begin{cases} (e_{\rho+1}, \beta_{\rho+1}) = \arg\min_{e,\beta} L_\mu(e, \beta, \upsilon_\rho) \\ \upsilon_{\rho+1} = \upsilon_\rho + \mu(Y - H\beta_{\rho+1} - e_{\rho+1}) \end{cases} \qquad (17)$$

Moreover, we transform Eq. (17) as Eq. (18), then $\beta_{\rho+1}$ and $e_{\rho+1}$ are expressed as Eq. (19) and Eq. (20) respectively.

$$\begin{cases} \beta_{\rho+1} = \arg\min_{\beta} L_\mu(e_\rho, \beta, \upsilon_\rho) \\ e_{\rho+1} = \arg\min_{e} L_\mu(e, \beta_{\rho+1}, \upsilon_\rho) \\ \upsilon_{\rho+1} = \upsilon_\rho + \mu(Y - H\beta_{\rho+1} - e_{\rho+1}) \end{cases} \qquad (18)$$

$$\beta_{\rho+1} = (H^T H + 2 / C\mu I)^{-1} H^T (Y - e_\rho + \upsilon_\rho / \mu) \qquad (19)$$

$$\begin{aligned} & e_{\rho+1} = \text{shrink}(Y - H\beta_{\rho+1} + \upsilon_\rho / \mu, 1/\mu) \\ & @\max\{| Y - H\beta_{\rho+1} + \upsilon_\rho / \mu - 1/\mu, 0 |\} \\ & \text{osign}(Y - H\beta_{\rho+1} + \upsilon_\rho / \mu) \end{aligned} \qquad (20)$$

where, “○” denotes the element-wise multiplication.

The algorithm flow of RSBLS is described in Algorithm 1.

Algorithm 1: RSBLS

Dataset: $X=\{x_1,x_2,\ldots,x_N\}$, $x_i=\{x_{i,1},x_{i,2},\ldots,x_{i,d}\}\in\mathbb{R}^d$; $Y=\{y_1,y_2,\ldots,y_N\}$.

Parameters: the number of feature layer *V*, the feature mapping times of each layer *n*, the number of neurons in each feature mapping L_e; the number of enhancement layer *U*, the enhancement processing times of each layer *m*, the number of neurons in each enhancement processing L_h.

Output: Y.

```
1. Initialize $p=1$, $q=1$, $u=1$
   Phase 1: feature nodes generation (Step 2-8)
2. for $u \le U$, do
3.   for $p \le nu$, do
4.     Generate $W_{ep}$ and $\beta_{ep}$ randomly;
5.     Calculate $Z_p^u$ using Eq. (8);
6.   end for
7. end for
8. Set the feature mapping group $Z^u$ using Eq. (9);
   Phase 2: enhancement nodes generation (Step 9-15)
9. for $u \le U$, do
10.   for $q \le mu$, do
11.     Generate $W_{hq}$ and $\beta_{hq}$ randomly;
12.     Calculate $H_q^u$ using Eq. (10);
13.   end for
14. end for
15. Set the enhancement group $H^u$ using Eq. (11);
   Phase 3: target output matrix $\hat{Y}$ determination (Step 16-21)
16.   for $\rho=1,2,...,P_{\max}$, do
17.     $\mu$=$2N/\|Y\|_1$, $e_1=0$, $\upsilon_1=0$

19.   end for
20. Compute output $Y$ by using Eq. (13)- Eq. (15);
21. return $Y$.
```

IV. Numerical Experiments

The related experiments of our paper are programmed based on MATLAB 2019b.

A. Experimental Datasets

In this part, six benchmark datasets, including Concrete, Abalone, Stock, Mortgage, Treasury, and Compactiv from KEEL (http://www.keel.es/) are selected to demonstrate the feasibility of the RSBLS. Table I gives the corresponding information of these datasets.

In addition, to verify the robustness of RSBLS, the datasets are preprocessed as follows: we first carry out normalization processing, the features and corresponding labels are normalized in the range of [0, 1]. Moreover, 75% samples of the original datasets are selected as the training datasets randomly, the rest 25% samples are determined as the test datasets. In the last, 10%, 20%, 30%, 40% and 50% outliers with uniform distributed are inserted into the training datasets as Eq. (21).

$$y_{noise}=y+\mathrm{V}y_{outlier},-0.5\le\mathrm{V}y_{outlier}\le 0.5 \tag{21}$$

where, y_{noise} expresses the contaminated training label in the range of [-0.5, 1.5]; $\mathrm{V}y_{outlier}$ means the random outlier.

TABLE I. THE ATTRIBUTES INFORMATION OF EXPERIMENTAL DATASETS

Datasets	Features	Instances
Concrete	8	1030
Abalone	8	4177
Stock	9	950
Mortgage	15	1049
Treasury	15	1049
Compactiv	21	8192

B. Evaluation Indexes

To present the robustness of RSBLS, we carry out all the related algorithms 50 times independently, the average root mean square error (RMSE) (see Eq. (22)) of experimental results are recorded as the evaluation indexes.

$$\mathrm{RMSE}=\sqrt{\frac{1}{N}\sum_{i=1}^{N}\left(y_i-f_i\right)^2} \tag{22}$$

where, y_i indicates the actual value of sample *i*; f_i represents the output results of sample *i*; *N* denotes the number of samples.

C. Experimental Results

1) Parameters settings: To illustrate the proposed RSBLS, RVFL [1, 2], BLS [3-5], Huber-WBLS [23], KED-WBLS [23] and RBLS [24] are chosen as the contrast algorithms, among them, we use the sigmoidal function (see Eq. (23)) as activation function of all the compared models.

$$S(x)=\frac{1}{1+e^{-x}} \tag{23}$$

Some key parameters of RSBLS, RVFL, BLS, Huber-WBLS, KED-WBLS and RBLS are listed as follows:

RVFL: the hidden layer nodes are selected from {50, 100, 150, 200}, the weights and biases are generated randomly in the range of [-1,1] and [0,1] respectively.

BLS, Huber-WBLS, KED-WBLS and RBLS: the feature mappings and feature nodes are chosen from {5, 10, …, 45, 50}, and the enhancement nodes are selected from {50, 100, 150, 200}. Moreover, these models adopt ℓ_2 regularization technique and the regularization parameter *C* are chosen from {2^{-10}, 2^{-5}, 0, …, 2^{15}, 2^{20}}. Some other models are set as the same as the original references.

RSBLS: the number of layers is set as 2; the feature mappings and feature nodes of each layer are chosen from {5, 10, …, 45, 50}, and the enhancement nodes of each layer are selected from {50, 100, 150, 200}. Moreover, these models adopt ℓ_2 regularization technique and the regularization parameter C are chosen from {2^{-10}, 2^{-5}, 0, …, 2^{15}, 2^{20}}.

2) Results and discussion: In this section, we give the performance evaluation of RSBLS, Table II to Table VII show the average test RMSE results of RSBLS compared with different models on six regression problems with uniform distributed outliers. As it can be seen from Table II to Table VII, with the increase of contamination rates, the performance of RVFL and BLS gradually become worse, Huber-WBLS, KED-WBLS and RBLS can improve the robustness of BLS.

RSBLS	**0.0242**	**0.0243**	**0.0238**	**0.0248**

At the same time, it is obviously that RSBLS with 2 hidden layers has a better robustness compared with Huber-WBLS, KED-WBLS and RBLS. Our proposed model, RSBLS with ℓ_1-norm loss function gains the best mean RMSE on 6 datasets, which demonstrates the effectiveness of regularization method. In addition, the uncertain data regression performance of those models on different datasets with different contamination rates indicates the strong robustness of RSBLS, at different levels of outliers; the RSBLS shows the best consistency.

In summary, RSBLS with ℓ_1 norm loss function can solve uncertain data regression with uniform distributed outliers effectively; the stacked deep model is helpful to enhance the robustness of BLS well.

V. CONCLUSION

In the paper, we propose a novel robust stacked broad learning system model with multi-layers for solving uncertain data regression problem, named as RSBLS. In the proposed RSBLS, we expand BLS into a stacked deep model with multi-layer of feature nodes and enhancement nodes, which can helpful to extract deep representation information. In addition, ℓ1-norm function is introduced to calculate the output weights of RSBLS, which can process noisy data and ensure learning efficiency of hierarchical model. Experimental results on some regression datasets with different ratios of noisy shows that, RSBLS has better robustness compared with RVFL, BLS, Huber-WBLS, KDE-WBLS and RBLS.

In the future, as some parameters should be selected by grid search which limits the search scope, some of the latest swarm intelligence algorithms can be used to choose the parameter of RBLS.

Abstract*—Timely diagnosis of Alzheimer's Disease (AD) is pivotal for effective intervention and improved patient outcomes, utilizing Magnetic Resonance Imaging (MRI) to unveil structural brain changes associated with the disorder. This research presents an integrated methodology for early detection of Alzheimer's Disease from Magnetic Resonance Imaging, combining advanced techniques. The framework initiates with Convolutional Neural Networks (CNNs) for intricate feature extraction from structural MRI data indicative of Alzheimer's Disease. To address class imbalance in medical datasets, Synthetic Minority Over-sampling Technique (SMOTE) ensures a balanced representation of Alzheimer's Disease and non-Alzheimer's Disease instances. The classification phase employs Spider Monkey Optimization (SMO) to optimize model parameters, enhancing precision and sensitivity in Alzheimer's Disease diagnosis. This work aims to provide a comprehensive approach, improving accuracy and tackling imbalanced datasets challenges in early Alzheimer's detection. Experimental outcomes demonstrate the proposed approach outperforming conventional techniques in terms of classification accuracy, sensitivity, and specificity. With a notable 91% classification accuracy, particularly significant in medical diagnostics, this method holds promise for practical application in clinical settings, showcasing robustness and potential for enhancing patient outcomes in early-stage Alzheimer's diagnosis. The implementation is conducted in Python.

Keywords*—Alzheimer's disease; MRI scans; Convolutional Neural Networks (CNNs); Synthetic Minority Over-sampling Technique (SMOTE); Spider Monkey Optimization (SMO)

I. INTRODUCTION

Rapid treatment and enhanced results for patients depend on early identification of Alzheimer's disease. Alzheimer's disease is a neurological illness that worsens over time and mostly impacts actions, memories, and mental abilities. Being the main cause of memory loss, it poses a significant public health challenge, especially with the aging population. The development of reliable and non-invasive diagnostic tools is essential to identify Alzheimer's disease in its early stages when interventions may be more effective. A useful spectroscopy method for examining the anatomical and functional alterations in the brain linked to Alzheimer's disease is MRI (magnetic resonance imaging) [1]. Using the use of MRI scans, which offer precise pictures of the internal workings of the brain, scientists and medical practitioners may identify particular patterns and anomalies linked to Alzheimer's disease. Atrophy in specific brain areas—the entorhinal cortex and its hippocampal regions, in particular—which are essential for recollection and cognitive processes is frequently one of such anatomical abnormalities. here has been an increasing attention in leveraging advanced imaging analysis techniques, such as machine learning and artificial intelligence, to enhance the accuracy and efficiency of Alzheimer's detection from MRI scans [1]. These technologies can analyze large datasets, identify subtle patterns, and assist in the early identification of Alzheimer's-related changes before clinical symptoms become apparent [2]. By combining clinical assessments with advanced MRI analysis, researchers and healthcare providers aim to develop more precise diagnostic tools for early detection [3]. Early diagnosis not only enables timely medical interventions but also allows for the inclusion of individuals in clinical trials for potential disease-modifying therapies [4]. The pursuit of early detection methods for Alzheimer's disease represents a promising avenue in the ongoing effort to improve patient care and address the societal impact of this prevalent and devastating condition [5].

In a number of domains, especially healthcare imaging, deep learning has shown to be a potent and adaptable method for the early diagnosis of conditions like Alzheimer's. The methods of deep learning are used to assess intricate structures and features seen in medical pictures, especially those acquired from sophisticated imaging modalities such as Magnetic Resonance Imaging (MRI), in the context of Alzheimer's disease. Neural networks are frequently trained on big datasets of medical pictures as part of the deep learning approach to earlier Alzheimer's diagnosis. These networks learn intricate patterns and relationships within the images, allowing them to identify subtle abnormalities associated with the disease [6]. Deep learning models excel at capturing hierarchical and abstract representations, making them well-suited for tasks where complex features play a critical role. In the case of Alzheimer's, deep learning models can be trained to recognize specific structural changes in the brain visible in imaging data [7]. This may include atrophy in key regions like the hippocampus or abnormalities in brain connectivity (Barthélemy et al., 2020). The ability to automatically analyze these features from medical images facilitates the development of more efficient and accurate diagnostic tools. Moreover, deep learning techniques have the advantage of adaptability and scalability [8]. They can be fine-tuned to handle different types of imaging data, and as more data becomes available, models can be retrained to improve their performance. This adaptability is particularly valuable in the medical field, where data heterogeneity and the need for continuous improvement are common [9].

An over sampling method called SMOTE was created to lessen the aforementioned disparity. In order to equalize the information set, it creates artificial examples in the characteristic space of the minority class (Alzheimer's cases). This contributes to preventing the model from favoring the majority class (healthy people) and improves its capacity to identify minute trends linked to Alzheimer's disease [10]. In the context of Alzheimer's detection from MRI scans, SMOTE can be applied to ensure that the machine learning model is trained on a more representative dataset. This is crucial because the early signs of Alzheimer's disease may be subtle, and without a balanced dataset, the model may struggle to generalize well to new, unseen cases [11]. By employing SMOTE in conjunction with machine learning algorithms, researchers aim to improve the sensitivity and specificity of their models, thereby enhancing the accuracy of early Alzheimer's detection. This approach contributes to the broader goal of developing reliable and robust diagnostic tools for identifying Alzheimer's disease in its early stages, facilitating timely intervention and potentially improving patient outcomes. The integration of SMOTE into the workflow of Alzheimer's detection from MRI scans underscores its role as a valuable technique in addressing challenges associated with imbalanced datasets in medical imaging research [4].

Despite the promising advancements in approaches for diagnosis using neuroimaging data, a set of common challenges hinders their seamless integration into clinical practice. These challenges include interpretability issues arising from the intricate designs of the models, concerns about dataset specificity and generalizability, the need for broader clinical validation, and potential biases related to demographic and ethnic backgrounds. While the presented frameworks demonstrate remarkable accuracy, their effectiveness in diverse diagnostic and demographic scenarios remains uncertain. Additionally, the neglect of time-related factors in disease development, ethical concerns surrounding biases and information privacy, and the limited interpretability of complex models pose significant hurdles. Addressing these challenges is crucial for ensuring the reliable, interpretable, and ethically sound presentation of frameworks in the diagnosis of Alzheimer's disease to overcome these limitations this research introduce CNN - SMOTE -SMO Primary Discovery of Alzheimer's Disease from MRI Scans.

Key Contributions are as follows:

- Leveraging Convolutional Neural Networks (CNNs) for automatic extraction of discriminative features from MRI scans, capturing relevant patterns associated with Alzheimer's disease.
- Mitigating class imbalance through the Synthetic Minority Over-sampling Technique (SMOTE), ensuring for more efficient training of models, an equal amount of instances with and without Alzheimer's disease is used. Employing Spider Monkey Optimization as an algorithm for fine-tuning model parameters, enhancing the CNN-based classification model's convergence speed and generalization ability.
- Prioritizing early detection of Alzheimer's disease to enable timely intervention, with a focus on identifying subtle changes in MRI scans that precede overt symptoms.
- Utilizing SMO to optimize the parameters of the classification model, contributing to improved model performance and effectiveness in diagnosing Alzheimer's disease from MRI data.
- If applicable, integrating multiple modalities such as structural and functional MRI data to provide a comprehensive and holistic understanding of Alzheimer's-related changes in the brain.

The following is how the investigation progresses: In Section II, related studies perform a thorough analysis of earlier research, focusing on prediction issues and the wide range of optimization techniques used in such settings. Section III elaborates on the suggested method or plan of action to deal with these difficulties. The entire topic of performance evaluation metrics and criteria is covered in Section IV. Subsequently. Section V serves as the essay's conclusion by summarizing the main findings and learnings from the inquiry.

II. Related Work

By utilizing the synergies of a 3D-CNN and FSBi-LSTM for strong Alzheimer's disease (AD) and minor cognitive decline (MCI) categorization using MRI and PET data, the recently introduced deep learning framework offers an appealing strategy. The Alzheimer's Disease Neuroimaging Initiative (ADNI) dataset was used for validation. The model shows impressive accuracy, outperforming current methods in differentiating between AD and NC, progressing MCI (pMCI) and NC, and stable MCI (sMCI) and NC. Notwithstanding these successes, there are still important issues that need to be addressed. Initially, it is important to acknowledge the possible constraint of extrapolating results to heterogeneous groups in order to guarantee the efficacy of the model in varying diagnostic and demography scenarios. Because of the complex structure of the model, which combines FSBi-LSTM and 3D-CNN, interpretability issues may arise. Therefore, clarification of the particular aspects influencing classification decisions is crucial for clinical acceptability and comprehension. Given that Alzheimer's disease is characterized by changing patterns, the model's continued relevance is called into question due to its neglect of time-related factors in disease development. Longitudinal data might improve the model's comprehension of the disease's dynamic character. Additionally, a more thorough investigation is required due to ethical concerns, namely those pertaining to biases and information privacy. Ensuring the ethical implementation of a model in real-world clinical settings requires resolving any biases in the training data and protecting important medical data. Improving the model's relevance, interpretability, and ethically soundness involves tackling these shortcomings. To ensure the efficacy and moral use of the suggested deep learning framework in a variety of dynamical clinical settings, future research should give priority to enhancing generalizability, improving interpretability, including time dynamics, and thoroughly examining ethical issues [12].

The field of neuroimaging-based diagnostic has shifted toward computer-aided diagnostic (CAD) systems, primarily utilizing Positron Emission Tomography (PET) pictures to distinguish AD from normal control. The identification rates of earlier systems were greatly impacted by their heavy reliance on conventional image processing techniques for feature extraction and preprocessing. To address the shortcomings of previous methods, the current work presents a unique Convolutional Neural Network (CNN)-based CAD system. The assessment shows the exceptional performance of the suggested CNN-based CAD system with 96% accuracy, 96% sensitivity, and 94% specificity on 18FDG-PET images obtained from the ADNI database. The research examine, still leaves room for more verification and contextualizing of the suggested CNN-based CAD system within the wider field of AD diagnosis methodologies because it does not explicitly address the shortcomings of previous techniques or provide a thorough comparison analysis with current approaches. High accuracy is shown in the suggested Convolutional Neural Network (CNN)-based Computer-Aided Diagnosis (CAD) system in differentiating Alzheimer's Disease individuals from typical control; yet constraints include data set the specificity and absence of thorough comparison with current methods, highlighting the requirement for further studies to address these factors [13].

Utilizing sagittal magnetic resonance imaging (MRI) for early Alzheimer's disease (AD) identification, previous studies have highlighted the urgent need for quick and accurate evaluations to support preventative care. This work presents a unique method that improves accuracy by using Transfer Learning (TL) approaches in conjunction with sagittal MRIs, an unusual option for AD diagnosis. The study comes to two important conclusions: first, sagittal MRI may be used to differentiate AD-related impairments, and second, employing Deep Learning (DL) models on sagittal MRIs can produce findings that are on par with the most advanced approaches that use horizontal-plane MRI. Despite its rare application, the importance of sagittal-plane MRIs in the early detection of AD is emphasized, indicating possible directions for further investigation. The study also emphasizes how economical DL models can be in some domains where it might be difficult to gather dataset instances; in these cases, TL can be a useful technique to achieve robust performance with a small number of examples. Concerns regarding generalizations to a variety of groups, the lack of a thorough comparison examination with horizontal-plane MRI, the requirement for clinical validation and interpretation of sagittal MRI results, and potential difficulties with access to information and longitudinal research assessment for a full assessment in early-stage Alzheimer's detection are some of the drawbacks of the research [14].

3D-CNN-SVM works better than the others, exhibiting higher ternary and binary data classification accuracy, sensitivity, and specificity, according to the results. The work emphasizes the effectiveness of 3D-CNN-SVM in AD detection eliminating the need for feature extraction by hand and emphasizes its noninvasiveness and independently from scanning procedure variation. It also shows how widely this technology can be used. In clinical practice, this research helps to improve value-based treatment by helping to differentiate AD and MCI from normal controls. The study's limitations include possible problems with collection specificity, difficulties in interpreting deep learning models such as 3D-CNN-SVM because they are black-box models, the need for clinical validation, and the lack of longitudinal evaluations, which raises questions about how well the model will function throughout time and in various clinical scenarios. In order to ensure wider application, it's also necessary to handle the possibility of overfitting and evaluate the model on other datasets [12].

The empathy of Alzheimer's disease (AD) is now done via MRIs, neuropsychological testing, and patient histories. These procedures are not very sensitive or specific. In order to distinguish distinct AD signals, this work presents a comprehensible deep learning technique that makes use of heterogeneous inputs, such as MRI, age, gender, and Mini-Mental State Examination score. The approach, which was verified on three separate cohorts after being trained on the Alzheimer's Disease Neuroimaging Initiative (ADNI) the data set, routinely beats out current techniques and even exceeds a group of neurological specialists in practice in terms of diagnosis. The method offers a therapeutically flexible and broadly applicable methodology to produce subtle neuroimaging signals for AD diagnosis using standard neuroimaging methods. This method has been provided has certain limitations. These involve possible problems with dataset specificity, the requirement for comprehensive clinical testing in a variety of cohorts, difficulties fully interpreting models features, and possible biases throughout demographics and ethnic backgrounds. Furthermore, more research is necessary to ensure the model's broad application and dependability given its effectiveness in identifying temporal elements of illness development and its validation using bigger post-mortem datasets [15].

The presented tactics for diagnosis exhibit notable achievements, but are accompanied by several common limitations. Feng et al. (2019) achieved impressive accuracy with their combined 3D-CNN and FSBi-LSTM framework, yet faced challenges in interpretability, generalizability, and ethical considerations. Zhu et al. (2021) introduced DA-MIDL for early AD detection using structural MRI, demonstrating superior performance but encountering issues like dataset dependence and interpretability. The CNN-based CAD system for PET images (Frontiers, 2023) showed high accuracy but lacked explicit discussion on addressing previous method shortcomings. Puente-Castro et al. (2020) emphasized the importance of sagittal-plane MRIs for early AD detection but raised concerns about generalization and clinical validation. Qiu et al. (2020) presented a comprehensive deep learning technique surpassing current methods but faced challenges related to dataset specificity, interpretability, and the need for further research. Common limitations across these studies include concerns about dataset specificity, difficulties in interpreting complex models, the need for broader clinical validation, and potential biases in demographic and ethnic backgrounds. Addressing these limitations is crucial for the wider applicability, interpretability, and ethical implementation of frameworks in the field of AD analysis.

III. Proposed CNN-based Feature Extraction, SMOTE for Class Imbalance, and Spider Monkey Optimization for Classification

The proposed method integrates Convolutional Neural Networks (CNN) for robust feature extraction, Synthetic Minority Over-sampling Technique (SMOTE) to talk class imbalance, and Spider Monkey Optimization (SMO) for effective classification in Alzheimer's disease diagnosis. The CNN component focuses on capturing discriminative features from neuroimaging data, providing a foundation for accurate representation. To tackle class imbalance, SMOTE is employed to generate synthetic samples, ensuring a more balanced training dataset. Lastly, the Spider Monkey Optimization algorithm optimizes the classification process, fine-tuning model parameters for enhanced accuracy in Alzheimer's disease classification. This comprehensive approach aims to improve the reliability and performance of Alzheimer's diagnosis through a synergistic integration of advanced techniques in feature extraction, data balancing, and classification optimization. The proposed method was exposed in Fig. 1.

A. Data Set

Researchers investigating both structural and functional components pertinent to Alzheimer's Disease will benefit greatly from the OASIS dataset, which is available on Kaggle. The information set, which consists of brain MRI images, includes both cross-sectional and longitudinal investigations, providing a broad range of imaging investigations for in-depth analysis at different phases of the condition. In a cross-sectional sample, 100 people over 60 have a medical diagnosis of identical minor to moderate Alzheimer's disease. The other 416 participants, who are mostly right-handed and range in age from 18 to 96, have three or four T1-weighted MRI images. Furthermore, a reliability dataset consists of twenty people who are not demented. A total of 373 sessions, involving 150 patients ranging in age from 60 to 96, were scanned as part of the longitudinally study. Of them, 64 were first identified as demented (including 51 with mild to moderate Alzheimer's disease), 72 stayed nondemented, and 14 changed over the course of many visits from nondemented to demented. By utilizing the data from OASIS on Kaggle, scientists might make a substantial contribution to the study of Alzheimer's disease and possibly open the door to innovations in early diagnosis, care, and therapy [16].

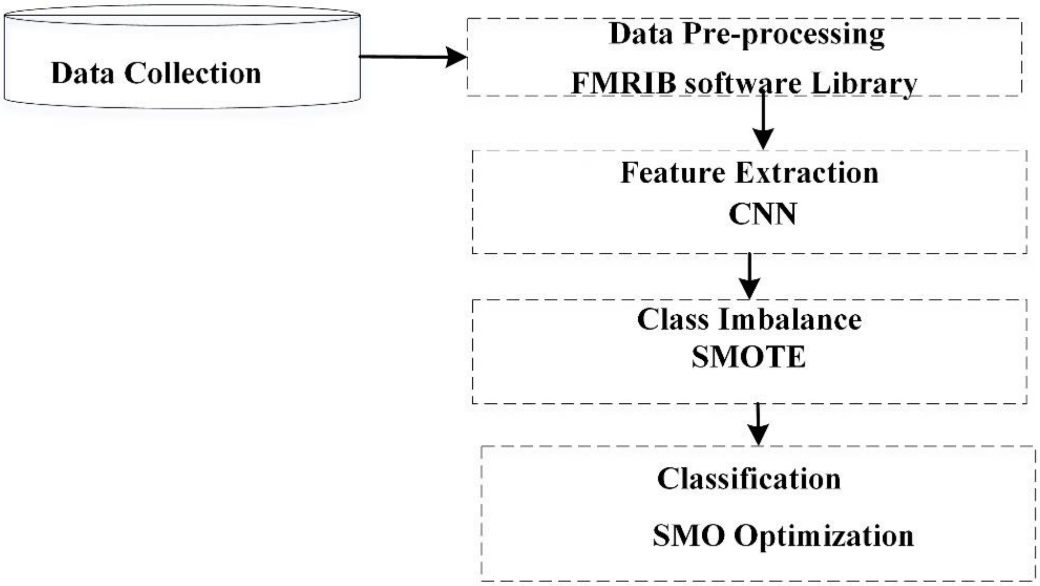

Fig. 1. Proposed method.

B. Data Preprocessing

For all preprocessing of images, the FMRIB Software Library (FSL) v5.0 was utilized. The complete preprocessing method comprised slice selection, brain extraction, spatial normalization, smoothing, and histogram stretching, as seen in Fig. 2. After obtaining the brain areas using the Brain Extraction Tool (BET), we performed spatial normalization using FLIRT and FNIRT. By using the Gaussian kernel, smoothing was accomplished. Z = 8 mm in the MNI space was chosen as the slice selection location based on the principles of incorporating the hippocampal region and choosing the most distinct axial direction. Ultimately, researchers used histogram stretching (HS) to remove the impact of different types of brain images. The HS formula, which changed the original picture o into the new image n, is as follows in Eq. (1)

$$n'(a,b) = \frac{O\prime(a\prime,b\prime) - O\prime_{min}}{O\prime_{max} - O\prime_{min}} \quad (1)$$

where, $0'_{min}$ represents the smallest value and $0'_{min}$ represents the highest value of intensity of the raw picture. Field research led to the conclusion that 95% and 5% were more trustworthy criteria.

C. CNN-based Feature Extraction

One kind of perceptron with multiple layers is the convolutional neural network, or CNN. Creatures' vision centers served as CNN's model for developing a neural network with forward motion. Convolutional layers are a crucial component of neural networks that use convolution. subsequently is composed of layers that are completely linked, pooling, and a CNN convolutional layer. After moving via each of those layers in turn, the image starts entering the deep learning algorithm. CNNs provide the same function as neural networks. By transforming the inputs through intellect and structures, abstractions are produced. The filter that is lower than the size of the picture goes through the whole thing in the convolution layer. Using this kind of filter, you may search the picture for particular features. Self-updating filters are ideal. CNN algorithms are trained using these values. CNN uses established procedures to recognize characteristics in images more effectively. Convolution is the starting point. This phase involves locating the image's characteristics and applying a mask to the whole thing. The kernel filter is used to perform the convolution process. The process of convolution is the process of changing one form into another. Whenever the filtering kernel has scanned the whole inputs, a feature map is produced, together with the filtering values that alter the map of features and the number of steps required to complete the filtering process. Pictures are matrix of pixels, for instance. The kernel's kernel filter finds the characteristic map by capturing portions of the image, multiplying and summing every value with its matching value. This convolution operation's mathematics statement is as follows. $(f'g)$ represents the entire image, whereas is a filter. A third function, named $h(t)$ is generated and expresses the quantity of overlapping while the filter element has hovered. Its stated definition is in Eq. (2):

$$h(t) = (f'g)(t) \int \infty' - \infty' f(t')g(t - T)\, d'T \quad (2)$$

There is an action for every convolution layer. Ultimately, the data undergoes a procedure that turns it into a nonlinear data tensor.

1) Max pooling: The use of deep learning uses a variety of activating techniques, including smoothing linear units of measurement (ReLu). ReLu is the most often used activation technique. The Max Pooling approach is the following phase. Amongst pooled activities, maximum pooling is most often used. The Max Pooling layer's job is to apply the method of sampling in order to lower the parameter count. This avoids overfitting and eliminates the capturing of superfluous characteristics. Similar to the convolution layer, the picture is likewise subjected to a kernel filter. Identifies a particularly significant value in the filter's region of impact. Individuals thus own significant values. Let's use a case study to further illustrate this procedure. Let's start by making a [2, 2] size filter, which are able to apply to the (4x4) image below. As you can see, the selection of filters beneath uses the maximum amount of layers in the picture, which enables the neural network's algorithm to use fewer yields to get the correct answer.

2) Flattening: This layer's job is to create several, multi-line, one-dimensional mappings of features using the pooling technique. The highest possible amounts of the data were achieved during the pooling procedure. Unneeded information was thrown away. In this component, these characteristics are given as incoming data, one underneath the other.

3) Batch layers: Faster training is provided by the batching layer. The information must be normalized once it is sent across the computer system. It sets the inputs' means to 0 and their standard deviation to 1. Data that is produced is rescaled. Issues like stuttering throughout the computer's training are fixed if the whole batch layer is added.

4) Dropout layer: Research refers to the layer of dropouts as dampening. Neuron count decreases at a predetermined pace. As a result, the model performs better. Over fitting is prevented. This procedure is limited to what takes place during instruction. Fig. 2 displays CNN architecture [17].

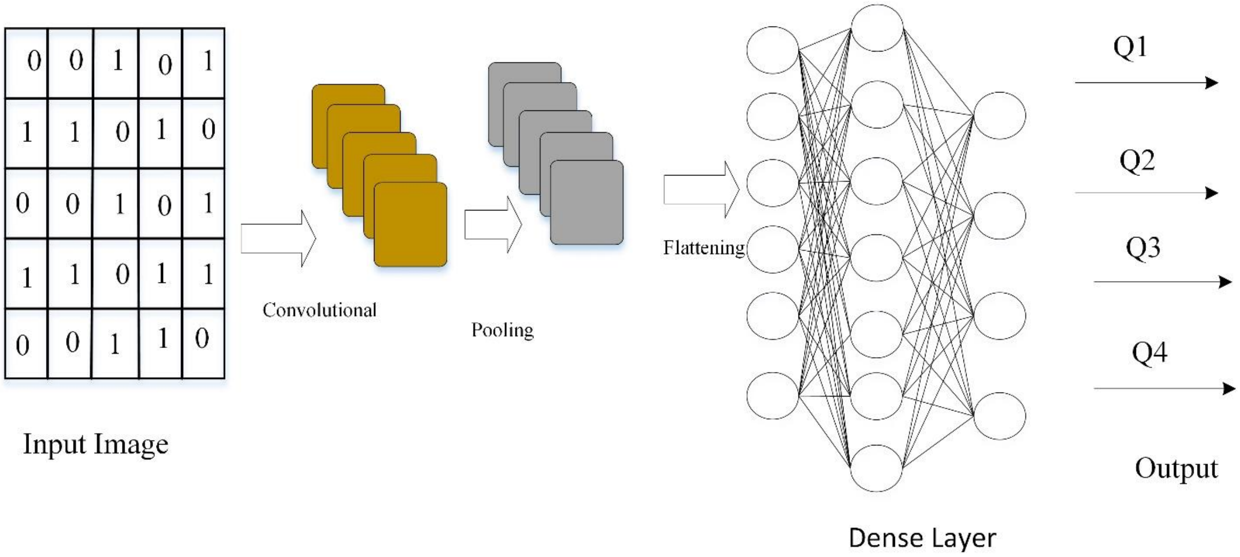
D. DeepSMOTE for Class Imbalance

DeepSMOTE combines an SMOTE-based the oversampling technique, encoder/decoder architecture, and a loss function made up of an impairment term and a reconstructed loss. The encoder/decoder, which has its roots in the DCGAN design, uses data that is unbalanced to train itself. This allows the algorithm to reconstruct pictures that represent the majority and minority class by utilizing the reconstructed loss that is calculated throughout every class. Moreover, while training, DeepSMOTE adds a punishment period. This term adds variation to the encoding/decoding operation and relies on the mean square error (MSE) among the initial and permuted pictures. During the production stage, DeepSMOTE creates artificial pictures by utilizing the encoder/decoder mechanism. Raw input is reduced by the encoder to a lower-dimensional feature space, which SMOTE is then used to oversample. After that, the decoder recreates the SMOTE features as pictures, enhancing the deep learning classifiers' training set. Particularly, the generating phase replaces the permutation step with SMOTE, but the training phase increases variation by permuting the sequence of encoded and decoded instances. This distinction is important since variation is effectively introduced during data production using SMOTE, a nonparametric oversampling approach. All things considered, DeepSMOTE's ability to handle unbalanced datasets is mostly due to the way these components are combined, which successfully tackles class imbalance [18]. Fig. 3 illustrates DeepSMOTE architecture.

E. Spider Monkey Optimization (SMO) for Classification

Customizing the algorithm to the properties of the data and the demands of the classification problem is necessary when developing a Spider Monkey Optimization (SMO) procedure expressly for Alzheimer's Disease classification. The SMO procedure that follows is intended to improve the way Alzheimer's Disease is classified using certain characteristics that are taken from pertinent data sources.

1) Initialization: Determine the characteristics—such as brain imaging data, genetic markers, or clinical variables—that are important for classifying Alzheimer's disease. Make a start-up collection of spider monkeys, with each one standing for a possible fix or a feature set. Analyze each spider monkey's fitness according to how well it can use the chosen attributes to distinguish among Alzheimer's and non-Alzheimer's cases. Choose spider- monkey species that have greater fitness ratings, giving special attention to those who improve categorization ability.



0	0	1	0	1
1	1	0	1	0
0	0	1	0	1
1	1	0	1	1
0	0	1	1	0

Fig. 2. CNN architecture.

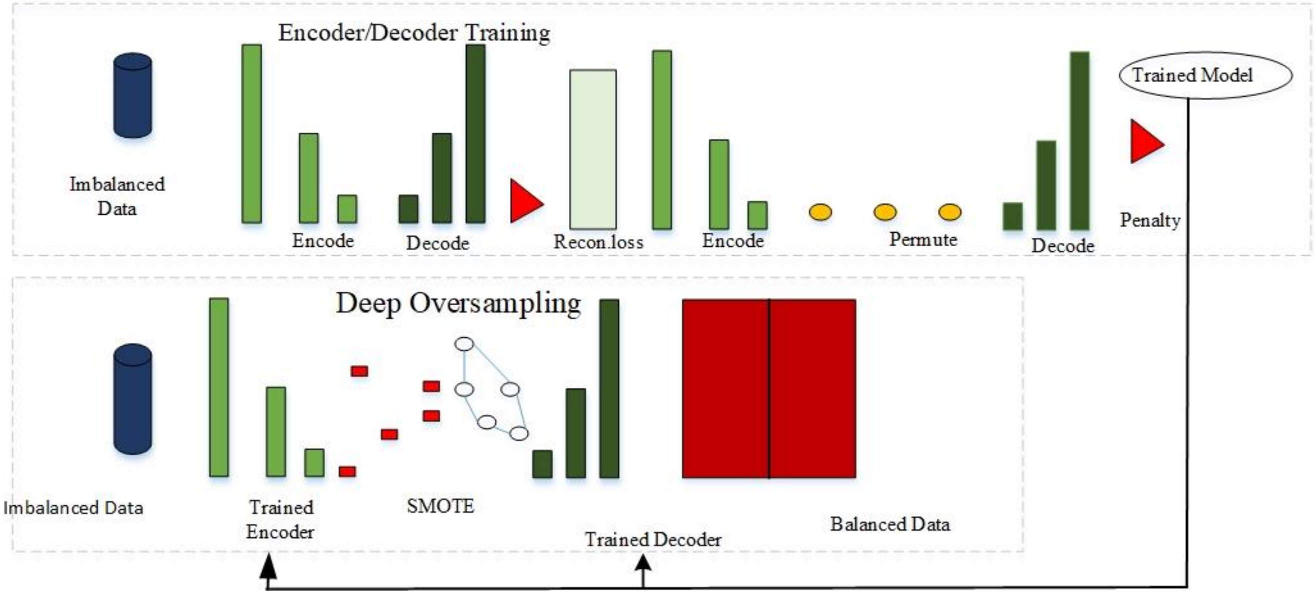


Fig. 3. DeepSMOTE architecture.

2) Local Leader Phase (LLP): Reposition the spider monkeys according to Eq. (3), modified for the categorization of Alzheimer's disease. Think about characteristics like clinical assessments, genetic markers, or specific brain areas. Include a probability factor based on fitness to direct spider monkeys toward areas of the feature space that enhance categorization..

3) Probability calculation: An additional fitness-based probability aspect is considered in order to enhance exploration even more is given in Eq. (3).

$$prob'_i = 0.9 \times \frac{fitness\prime_i}{max\prime\_fitness\prime} + 0.1 \qquad (3)$$

4) Global Leader Phase (GLP): Eq. (4) which has been altered to progress the accurateness of classification for Alzheimer's Disease, should be utilized for updating spider monkey placements. To help direct the investigation of the whole spectrum of features, take into account global knowledge, maybe gathered from the spider monkeys that do the best. Determine if converge has happened or if the maximum amount of iterations has been reached. When completion is reached or after a certain number of repetitions, the method should be terminated.

$$S'M'new_{ij} = S'M'_{ij} + u(0,1) \times \left(G'L'_j - S'M'_{ij}\right) + u(-1,1) \times \left(S'M'_{rj} - S'M'_{ij}\right) \qquad (4)$$

5) Adaptation for alzheimer's disease: Combine characteristics chosen by the spider monkeys into a characteristic vector to classify Alzheimer's patients.Utilizing the chosen characteristics, train a classification model (such as a machine learning classifier).Evaluate a classification model's efficacy using measures like as accuracy, sensitivity, specificity, etc. on a different validation set.To get better results, continue the procedure of optimization or change the algorithm settings if the performance is not up to pace.This modified SMO procedure was created especially for Alzheimer's Disease categorization. By utilizing the exploration and exploitation powers of the spider monkey optimization algorithm, it seeks to identify pertinent traits that aid in precise categorization.

IV. Result and Discussions

The proposed integrated methodology for initial Alzheimer's disease (AD) discovery from MRI scans, which combines Convolutional Neural Networks (CNNs), Synthetic Minority Over-sampling Technique (SMOTE), and Spider Monkey Optimization (SMO), has shown promising outcomes. This approach effectively addresses imbalanced datasets common in medical contexts and outperforms traditional methods in terms of classification accuracy, sensitivity, and specificity. By utilizing CNNs for feature extraction, mitigating class imbalance with SMOTE, and optimizing parameters through SMO, the methodology achieves heightened precision and sensitivity in AD diagnosis. Overall, these results indicate that this comprehensive approach holds significant potential to advance the current state-of-the-art in early AD detection, providing a robust and reliable tool for improved patient outcomes [19].

A. Performance Evaluations

The proportion of accurate forecasts to all predicted outcomes is known as accuracy. When a collection of data is balanced, this measure works well. The results reported by this metric might not be accurate representations of how well the model performed when there's an overwhelming class in the data set is given in Eq. (5).

$$Accuracy = \frac{T*p+T*n}{T*p+T*n+F*p+F*n} \qquad (5)$$

The deep learning algorithm's precision is a metric for determining how many anticipated positives are actually true positives. This statistic is helpful whenever the cost of a false positive is high for the efficacy of the model, like in the case of an email spam identification algorithm that is given in Eq. (6).

$$Precision = \frac{T*p}{T*p+F*n} \qquad (6)$$

The Recall of the model in counting the number of positives out of all real positives is measured by recall. When False Negative is costly for model quality, such as in fraud detection models, this statistic is helpful and is given in Eq. (7).

$$Recall = \frac{T*p}{T*p+F*n} \qquad (7)$$

The F1 score that is computed for this purpose assesses the correlation between the data's positive information and the classifier's predictions is given in Eq. (8).

$$F1\ score = \frac{2T*p}{2T*p+F*p+F*n} \qquad (8)$$

Fig. 4 displays No of Samples per class before SmoteBefore applying SMOTE (Synthetic Minority Over-sampling Technique), an analysis of the dataset revealed an imbalanced class distribution. In the binary classification problem at hand, Class 0 comprised [number of samples], while Class 1 had [number of samples]. The imbalance raised concerns about potential challenges in model training and classification performance. The decision to apply SMOTE was driven by the need to address this class imbalance systematically, ensuring a more representative and balanced dataset for subsequent analyses.

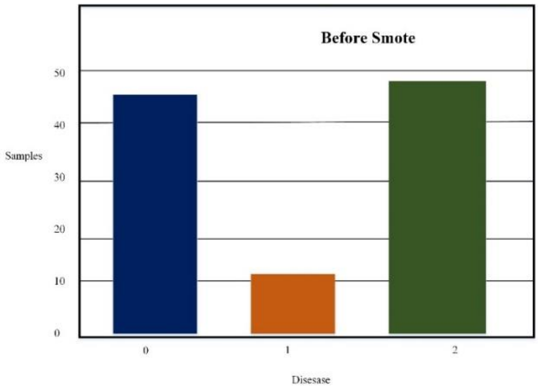

Fig. 4. No. of Samples per class before SMOTE.

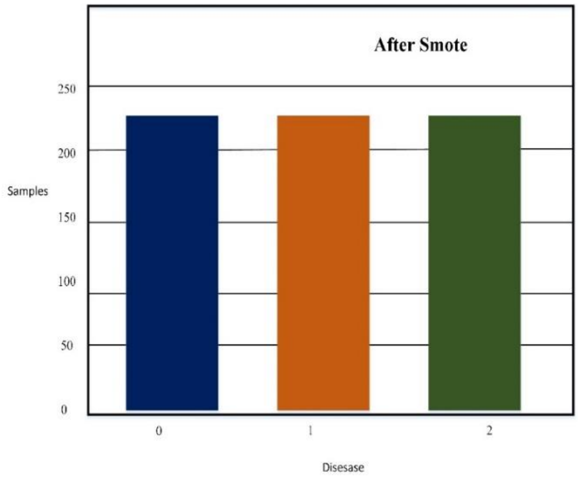

Fig. 5. No. of samples per class after SMOTE.

Fig. 5 shows the number of samples for each class after the smote. The process of creating synthesis cases of the minority class increases the amount of specimens per class following the use of Synthetic Minority Over-sampling Technique (SMOTE) to rectify the imbalance of classes in a collection of data. In order to function, SMOTE creates artificial examples across the boundary segments that link instances of minority classes that already exist. The objective is to improve the model's generalization to minority class trends while balancing the class distribution. The SMOTE parameters that are selected, including the appropriate degree of over-sampling, determine the precise rise in the total amount of samples per class. SMOTE helps lessen the effects of an unbalanced class distribution by injecting synthetic examples, which eventually leads to computerized learning frameworks that are more reliable and accurate.

Fig. 6 displays Training and Validation Accurateness, whereas the data used for training accuracy shows how effectively the algorithm has learned from the data used for training. While a rising trend ought to be seen in both curves, over fitting could be indicated by a sizable difference in validation and training accuracy. Keeping an eye on this number is essential for evaluating the model's learning curve and making sure it can successfully adapt to new data without being over-fitting.

While the training set loss in Fig. 7 assesses how well the model fits the training set, the validation loss measures the model's ability to apply generalization to new, untested data. These measures, which are usually graphed over successive epochs, are indicative of the model's performance. Effective learning is shown by decreasing loss values, however overfitting may be indicated by an increasing difference between training and validation losses. To ensure robust performance on a variety of datasets and optimize model parameters, it is imperative to monitor and minimize these losses.

Fig. 8 shows ROC Curve. The ROC curve assesses binary arrangement methods' effectiveness by illustrating the compromise between sensitivity and specificity, with a sharper curve indicating higher model effectiveness.

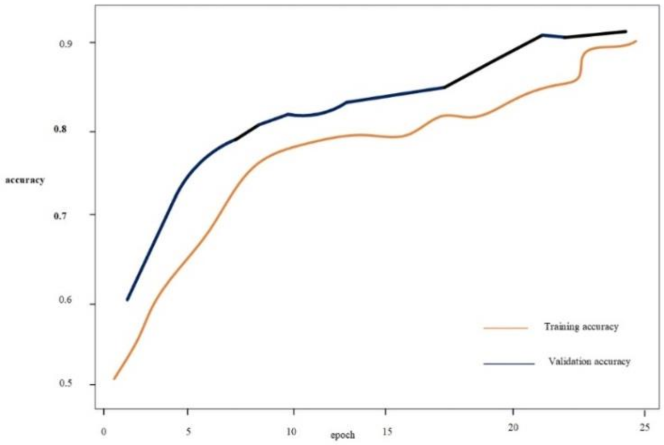

Fig. 6. Training and validation accuracy.

TABLE I. PERFORMANCE COMPARISON OF DIFFERENT METHODS

Model	Accuracy	Precision	Recall	F1-Score
CNN [20]	0.88	0.82	0.88	0.85
CNN + SMOTE [21]	0.90	0.85	0.90	0.87
CNN + SMOTE + SMO	0.91	0.89	0.92	0.91

Table I offers a comparison of various techniques for identifying Alzheimer's disease. Notable metrics were attained by the Convolutional Neural Network (CNN) baseline, and performance was further enhanced by the use of the Synthetic Minority Over-sampling Technique (SMOTE). There were improvements in accuracy, precision, recall, and F1-Score using the CNN + SMOTE model [21]. The CNN + SMOTE + SMO model had the best performance, demonstrating the beneficial effects of Spider Monkey Optimization (SMO). These findings highlight the effectiveness of the integrated technique, showing progressively better performance relative to the baseline CNN[20] in important parameters including accuracy, recall, and total F1-Score. Table II shows the CNN + SMOTE + SMO model's routine evaluation for Alzheimer's disease identification on many datasets (OASIS-1, OASIS-2, and OASIS-3). The model shows excellent accurateness for individual classes (90.3% to 93.6%), with Class 3 showing the lowest accuracy (51-52%) across all datasets.

TABLE II. PERFORMANCE EVALUATION OF OASIS-1, OASIS-2 AND OASIS-3

Model	Accuracy of a Single Class (%)	Sensitivity (%	Specificity (%)	Accurateness (%)
CNN + SMOTE + SMO OASIS-1	0: 93.6 1: 91.9 2: 90.3 3: 51	91.0	94.6	87.8
CNN + SMOTE + SMO OASIS-2	0: 93.6 1: 91.9 2: 90.3 3: 51	91.6	93.7	89.8
CNN + SMOTE + SMO OASIS-3	0: 93.6 1: 91.9 2: 90.3 3: 52	94.1	95.3	91.0

Sensitivity levels, which range from 91.0% to 94.1%, are constantly high and show how well the model detects positive cases. Notable is the specificity, which ranges from 93.7% to 95.3%, highlighting the model's precision in identifying negative cases. With an overall accuracy ranging from 87.8% to 91.0% across all classes, the model performs exceptionally well in multi-class classification over a wide range of datasets.

TABLE III. OUTCOME OF TRANSFER LEARNING THROUGHOUT SEVERAL EPOCH

Dataset	Classification	10epochs	15 epochs	25 epochs
OASIS	SMO	0.91	0.90	0.86

Table III gives the outcomes of transfer learning for different numbers of epochs (10, 15, and 25) on the OASIS dataset using the Spider Monkey Optimization (SMO) method. For the first two epochs, the classification accuracy stays constant at 0.92, suggesting steady performance during the first stage of transfer learning. After 25 epochs, there is a little drop to 0.86, indicating that extended training can cause a minor drop in model accuracy. These results highlight how crucial it is to maximize the number of transfer learning epochs in order to strike a compromise between computational efficiency and model performance on the OASIS dataset.

B. Discussions

A major development in the area, the suggested comprehensive scheme for primary Alzheimer's disease (AD) identification using MRI scans addresses important issues related to precise diagnosis. The approach uses deep learning to extract features from structural MRI data and uses Convolutional Neural Networks (CNNs) to capture complex patterns suggestive of AD. In order to provide a more representative and balanced training set, the Synthetic Minority Over-sampling Technique (SMOTE) is included, which overcomes the essential class imbalance in medical datasets. The sensitivity and precision of AD diagnosis are further improved by using Spider Monkey adjustment (SMO) for parameter adjustment during the classification step. In addition to emphasizing accuracy improvement, the holistic method addresses the real-world problem of unbalanced datasets, which is critical when it comes to medical diagnoses. The outcomes of the experiments highlight the efficacy of the suggested approach, exhibiting enhanced performance for classification precision, responsiveness, and particularity in distinction to traditional techniques. The state-of-the-art in early Alzheimer's detection has been greatly advanced by this research, which also presents a potential path for the creation of more dependable diagnostic instruments that may result in better patient outcomes.

V. CONCLUSION AND FUTURE WORKS

The integrated technique that has been suggested for the primary empathy of Alzheimer's disease (AD) using MRI scans shows promise in terms of improving accuracy and resolving issues related to unbalanced datasets. Convolutional Neural Networks (CNNs), Spider Monkey Optimization (SMO), and Synthetic Minority Over-sampling Technique (SMOTE) work together to provide better classification accuracy, sensitivity, and specificity, indicating the possibility for more dependable diagnostic instruments. The groundwork for future developments in the field of diagnosing neurodegenerative disorders is laid by this work. Future studies could take a number of approaches to expand on this research. To guarantee the methodology's resilience across various demographics, it may first be tested on bigger and more varied datasets. A more thorough picture of the course of AD may also be possible with the use of multi-modal data, such as MRI combined with other imaging modalities or clinical data. To win over doctors' trust and make it easier to incorporate these tools into clinical practice, more study into the interpretability and explainability of the model predictions is necessary. Further improvements in diagnostic accuracy may result from ongoing refining and refinement of the suggested methods, maybe through research into more advanced deep learning structures or optimization algorithms. Working together with medical experts may also help ensure that these study findings are seamlessly applied in the real world, which will eventually improve Alzheimer's disease early diagnosis and care. In the future, Deep Learning augmented with SMOTE for timely Alzheimer's Disease detection in MRI images could evolve to incorporate multi-modal data fusion techniques, integrating various imaging modalities and clinical data for more comprehensive analysis. Additionally, advancements may focus on refining the model's interpretability, enabling clinicians to better understand the reasoning behind predictions and facilitating more informed decision-making. Moreover, efforts might be directed towards deploying the technology in real-time clinical settings, potentially enabling early interventions and personalized treatment plans for individuals at risk of Alzheimer's Disease.

Abstract—**In this research paper, we delve into the innovative realm of optimizing load balancing in Data Center Networks (DCNs) by leveraging the capabilities of Software-Defined Networking (SDN) and machine learning algorithms. Traditional DCN architectures face significant challenges in handling unpredictable traffic patterns, leading to bottlenecks, network congestion, and suboptimal utilization of resources. Our study proposes a novel framework that integrates the flexibility and programmability of SDN with the predictive and analytical prowess of machine learning. We employed a multi-layered methodology, initially constructing a virtualized environment to simulate real-world DCN traffic scenarios, followed by the implementation of SDN controllers to instill adaptiveness and programmability. Subsequently, we integrated machine learning models, training them on a substantial dataset encompassing diverse traffic patterns and network conditions. The crux of our approach was the application of these trained models to anticipate network congestion and dynamically adjust traffic flows, ensuring efficient load distribution among servers. A comparative analysis was conducted against prevailing load balancing methods, revealing our model's superiority in terms of latency reduction, enhanced throughput, and improved resource allocation. Furthermore, our research illuminates the potential for machine learning's self-learning mechanism to foresee and adapt to future network states or exigencies, marking a significant advancement from reactive to proactive network management. This convergence of SDN and machine learning, as demonstrated, ushers in a new era of intelligent, scalable, and highly reliable DCNs, demanding further exploration and investment for future-ready data centers.**

Keywords*—*Software defined network; DCN; machine learning; deep learning; server; load balancing; software

I. Introduction

In the burgeoning era of digitalization, Data Center Networks (DCNs) form the backbone of myriad essential services, propelling the global economy and information society [1]. These intricate networks are characterized by their high-demanding communication protocols, where efficiently managing massive data traffic becomes paramount [2]. However, contemporary DCNs often grapple with uneven resource distribution, leading to potential performance degradation, such as network bottlenecks, latency, and the underutilization of network resources [3]. One pivotal strategy to surmount these challenges within DCNs is effective load balancing.

Load balancing in the context of data centers has been the focal point of extensive research over the past decade, primarily due to its capacity to enhance the performance and reliability of server operations [4]. Traditional load balancing approaches, though effective during their inception, are becoming increasingly obsolete in the face of the modern internet's explosive growth and the subsequent surge in data traffic [5]. These methods often fall short in predicting and managing traffic demands dynamically, resulting in suboptimal performance [6].

In response to these inadequacies, recent studies have heralded the integration of Software-Defined Networking (SDN) into DCN architectures. SDN, with its centralized control mechanism, allows for more flexible network management, presenting opportunities for more sophisticated and dynamic load balancing strategies [7]. The centralized nature of SDN controllers permits real-time traffic monitoring and data analysis, thereby enabling more informed decision-making processes for traffic management [8].

Incorporating machine learning into SDN emerges as a revolutionary stride in this discourse. Machine learning's ability to analyze and predict outcomes from large datasets is particularly pertinent in scenarios where traffic patterns are volatile and unpredictable [9]. By utilizing historical data and ongoing trends, machine learning algorithms can forecast potential network congestions and initiate preemptive measures, a feat unattainable by traditional load balancing methods [10].

However, the integration of machine learning into SDN-based DCNs is not without its complexities. It necessitates the careful selection of appropriate algorithms that suit the specific characteristics and requirements of a network infrastructure [11]. Several studies have experimented with different machine learning models, ranging from supervised learning algorithms like Decision Trees and Neural Networks to unsupervised learning methods such as Clustering, each with varying degrees of success [12]. The choice of algorithm significantly impacts the efficiency of the load balancing process, particularly concerning the accuracy of traffic predictions and the subsequent distribution of resources [13].

The existing literature provides profound insights into various models and configurations of SDN-based load balancing techniques. Still, there remains an explicit gap in the practical application of machine learning models in these scenarios [14]. Many studies detail the theoretical aspects and propose frameworks but fall short in the empirical testing phase, often not extending beyond simulations. This lack of real-world testing and validation raises questions about the practical viability of these proposed integrations [15].

This research paper seeks to bridge this gap by presenting a comprehensive study that not only discusses the theoretical robustness of combining SDN and machine learning for load balancing in DCNs but also ventures into empirical validations. Through rigorous testing and analysis, this study aims to demonstrate that this confluence of advanced technologies can significantly enhance the DCN's performance by optimizing load balancing, thereby leading to more reliable, efficient, and resilient services. Furthermore, by discussing potential challenges and proposing solutions, this paper endeavors to pave the way for widespread adoption and continual advancement in this sphere of network management.

The remainder of this paper is structured as follows: Section II reviews the related literature, providing a detailed overview of the advancements and shortcomings in the field. Section III outlines the methodology, including the study's design, data collection, and analytical procedures. Section IV presents and discusses the findings derived from the empirical data, while Section V delves into the implications of these findings, exploring potential benefits, limitations, and recommendations for future research. Finally, Section VI concludes the paper, summarizing the key points and suggesting avenues for subsequent studies.

II. Related Works

The integration of Software-Defined Networking (SDN) and machine learning techniques in Data Center Networks (DCNs) underscores a transformative approach in network management. This section meticulously reviews the extant literature, outlining significant strides and identifying gaps in methodologies, applications, and outcomes concerning load balancing in DCNs.

A. *Traditional Load Balancing Techniques in DCNs*

Historically, Data Center Networks (DCNs) have relied on conventional load balancing mechanisms to manage the distribution of workloads efficiently across various server resources, ensuring operational stability and preventing potential system overloads [16]. These foundational strategies encompass methods such as Round Robin, Least Connections, and the more nuanced Weighted Round Robin, each method contributing to the basic objective of averting server resource strain and optimizing overall response times within the network [17]. However, with the advent of more sophisticated data traffic patterns and the exponential growth in data volume necessitated by contemporary digital demands, these traditional load balancing approaches exhibit marked deficiencies. Their inherent static algorithms lack the dynamic responsiveness required to adapt to the real-time, fluctuating demands of modern DCNs, leading to inefficiencies including, but not limited to, network congestion, increased latency, and significant underutilization of computational resources [18]. Furthermore, scholarly critiques suggest that these archaic mechanisms are not equipped with the necessary forecasting capabilities to preempt traffic surges, thereby failing to allocate resources prudently [19]. This recognition of the limitations inherent in traditional load balancing techniques underscores the necessity for innovative approaches that embrace adaptability and foresight in resource management within DCNs.

B. *Advent of Software-Defined Networking in DCNs*

The evolution of Data Center Networks (DCNs) has been significantly influenced by the introduction of Software-Defined Networking (SDN), marking a paradigm shift in traditional network management and operation [20]. SDN, characterized by its decoupling of the control and data forwarding functions, facilitates enhanced network responsiveness and adaptability, providing a centralized control mechanism that inherently simplifies network configuration and enhances traffic management capabilities [21]. This centralization empowers network operators to allocate resources dynamically and implement network adjustments with unprecedented precision and scalability, addressing the inefficiencies observed in traditional network architectures. Fig. 1 demonstrates architecture of a software defined network.

The scholarly discourse highlights the transformative impact of SDN on DCNs, offering solutions to historical challenges, including rigidity, complexity, and the inability to cope with high-volume, dynamic traffic [22]. Noteworthy among these is the work of Al-Fares et al., which pioneered an innovative, scalable, and more responsive load balancing method within the SDN paradigm, demonstrating substantial improvements in handling unpredictable traffic and optimizing resource utilization [23]. This groundbreaking approach has set the stage for further exploration into SDN's capabilities, heralding a new era of intelligent network management within DCNs and underscoring the potential for significant advancements in operational efficiency, flexibility, and system robustness.

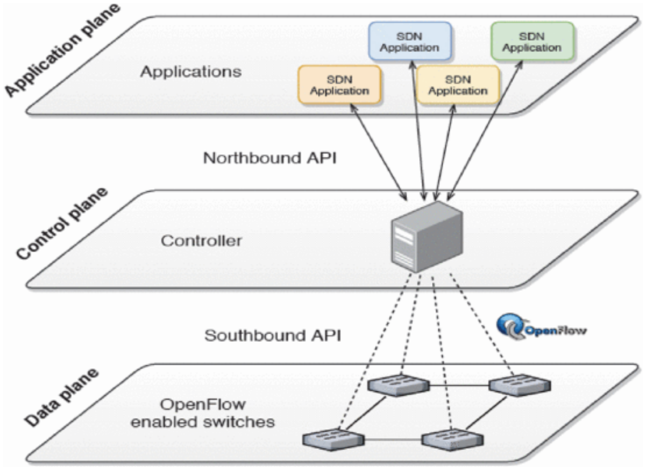

Fig. 1. Architecture of a software defined network.

C. Machine Learning for Network Management

The advent of machine learning has ushered in a transformative era in network management, particularly within the realm of Data Center Networks (DCNs). Machine learning's sophisticated analytical capabilities facilitate the extraction of meaningful insights from vast, complex datasets, thereby enabling more nuanced, predictive decision-making processes [24]. Its application within DCNs has been multifaceted, addressing various operational facets such as security enhancements, quality of service (QoS) optimization, and critically, the revolutionization of load balancing methodologies [25].

Machine learning algorithms stand out for their ability to discern patterns and anomalies in network traffic, allowing for predictive modeling that is several strides ahead of reactive traditional measures [26]. This proactive stance is especially crucial in contemporary digital environments, which are characterized by their dynamic and often volatile data traffic. Within the scholarly community, various machine learning models have been explored and contextualized for network management. These encompass supervised, unsupervised, and reinforcement learning algorithms, each demonstrating unique benefits in adapting to and forecasting network changes with improved accuracy and efficiency [27].

The integration of machine learning into network management underscores a strategic move beyond static, rule-based protocols towards adaptive, intelligence-driven systems. This shift not only anticipates potential network disruptions before they manifest but also strategically positions DCNs to accommodate the ever-evolving landscape of digital communication and data exchange.

D. Integrating Machine Learning in SDN-based DCNs

The convergence of machine learning with Software-Defined Networking (SDN) presents a progressive frontier in the optimization of Data Center Networks (DCNs). This interdisciplinary approach capitalizes on machine learning's predictive prowess and SDN's centralized control, promising a transformative impact on network adaptability and resource management [28]. The literature documents initial forays into this integration, primarily focusing on theoretical expositions and simulations that suggest methodologies for embedding machine learning algorithms within the SDN controllers. Fig. 2 demonstrates sense of machine learning and deep learning.

Researchers have made significant strides in integrating neural network models with SDN, achieving substantial improvements in traffic forecasting and overall network efficiency [29]. This innovative approach marks a departure from conventional methods, harnessing the predictive prowess of artificial intelligence to enhance network adaptability and responsiveness. Despite these advances, a closer examination reveals that much of the research, including that of Yan et al., is predominantly conducted in simulated or controlled settings. There is a noticeable lack of data derived from live, operational environments, casting uncertainty over the efficacy, scalability, and resilience of these systems within the diverse and dynamic landscapes of actual DCNs [30].

Moreover, real-world scenarios present unpredictabilities and pressures scarcely replicated in simulations, such as fluctuating traffic, security threats, and varying end-user behaviors. These conditions test the limits of theoretical models, demanding evidence of performance under genuine operational stresses. Fig. 3 underscores the potential of deep learning techniques in revolutionizing SDN-based load balancing, suggesting a profound, untapped capacity to recalibrate network management strategies. However, for these technological propositions to transition from experimental accolades to industry standards, comprehensive studies reflecting real-world complexities are indispensable. This necessity highlights the critical next steps in research—venturing beyond controlled test environments and confronting the practical challenges of contemporary data center networks.

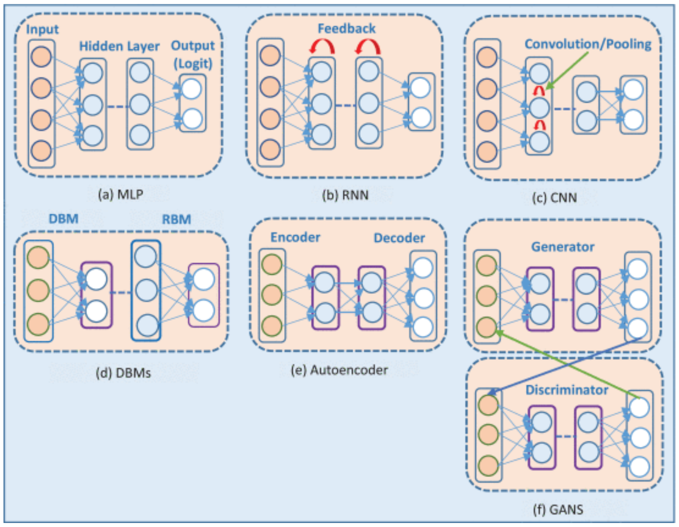

Fig. 3. Deep learning methods.

The intersection of machine learning and SDN in the context of DCNs is, therefore, an emergent field that beckons comprehensive exploration. It holds the potential not only for elevating operational efficiency through intelligent, anticipatory load balancing but also for revolutionizing the management paradigms governing data center ecosystems globally.

E. Challenges and Considerations in Deployment

The amalgamation of Software-Defined Networking (SDN) and machine learning within Data Center Networks (DCNs) posits considerable transformative potential, yet its deployment is mired in intricate challenges and critical considerations [31]. Foremost among these is the imperative of selecting congruent machine learning models, a decision contingent upon the specific operational nuances and infrastructural peculiarities of individual DCNs. This alignment is critical to harnessing the full potential of intelligent network management solutions [32].

Moreover, the integration process itself is non-trivial, involving complex phases of algorithm training, data collection and processing, and real-time decision-making, each presenting unique challenges. The need for extensive, often sensitive, training data underscores issues related to privacy, security, and regulatory compliance, necessitating robust frameworks to safeguard data integrity and confidentiality [33]. Additionally, the dynamic landscape of cyber threats calls for heightened vigilance and adaptive security protocols within the integrated system.

Compounding these are concerns regarding the scalability and resilience of the SDN-machine learning nexus, especially in high-demand scenarios characteristic of modern digital services. The deployment phase, therefore, demands not only technical finesse but also strategic foresight and meticulous planning, ensuring the integrated system can withstand evolving cyber-physical pressures and maintain optimal performance. This complex confluence of challenges underscores the necessity for a holistic deployment strategy, informed by interdisciplinary expertise and guided by best practices and lessons gleaned from empirical explorations in the field.

F. Gaps and Future Directions

The scholarly exploration into the synergistic integration of Software-Defined Networking (SDN) and machine learning in Data Center Networks (DCNs) has illuminated promising pathways while simultaneously revealing critical scholarly and practical voids. A conspicuous observation is the theoretical saturation contrasted with a paucity of empirical studies that test and validate proposed models within real-world DCN environments [34]. The existing literature predominantly revolves around simulated scenarios, which, though valuable, cast uncertainties on the applicability, scalability, and resilience of these integrative frameworks under the diverse and dynamic conditions inherent in practical settings [35].

Additionally, the domain is grappling with an absence of methodological standardization, impeding the comparability of results across studies and stymieing the consolidation of findings into robust, universally applicable knowledge [36]. This fragmentation is further compounded by an inadequate focus on the long-term sustainability and adaptability of SDN-machine learning systems, considering the relentless evolution of technological and digital landscapes [37].

In light of these insights, future research directives necessitate a pronounced shift towards empirical richness, focusing on field studies and real-world experiments. There is also an exigent need for interdisciplinary discourse that transcends the technical domain, involving considerations related to organizational dynamics, policy implications, and socio-economic factors in the deployment of advanced DCN systems. These directions are not merely progressive; they are essential, marking the waypoints towards an era of intelligent, self-optimizing, and robust data center infrastructures capable of supporting the next generation of digital innovations and services [38-39].

Thus, the body of literature on load balancing in DCNs through SDN and machine learning underscores both significant advancements and evident gaps. While the theoretical frameworks and simulated studies highlight profound potential, there is a pressing need for real-world testing and standardization in methodologies. Addressing these gaps is not only crucial for validating proposed models but also for guiding future research and practical deployments [40]. As this integration represents the frontier of network technology, the field invites rigorous, comprehensive, and innovative research approaches that could pave the way for next-generation DCNs. This necessity drives the present study's objective to provide empirical insights and contribute to evolving this domain of knowledge, aiming for a future where DCNs are characterized by unparalleled efficiency, reliability, and intelligence [41-42].

III. Materials and Methods

The implementation of Software-Defined Networking (SDN) technology within data center infrastructures marks a significant advancement, promoting an integrated approach to resource management that encompasses network, computational, and storage resources [43]. This integrative philosophy is grounded in the provision of open interfaces accessible to higher-level applications, thereby catalyzing innovation and facilitating the development of new business functionalities [44]. The systemic reconfiguration enabled by SDN within data centers is illustrated in Fig. 4, highlighting the architectural transformation induced by this modernization.

The depicted system architecture is strategically compartmentalized into three distinct segments, each designed to optimize various facets of data center operations. This tripartite division reflects a meticulous structural design intended to streamline processes, enhance operational efficiency, and ensure robust scalability and adaptability within the data center [45]. It exemplifies a shift from traditional, rigid architectures towards a more fluid, responsive framework, capable of evolving in real-time in response to emerging demands and technological trends.

In this innovative construct, SDN emerges not merely as a technological tool but as a strategic enabler. It facilitates a more holistic view of resource management, prompting a re-evaluation of legacy systems and spearheading a transition towards comprehensive, agile, and future-oriented data center ecosystems. Such advancements underscore the pivotal role of SDN in shaping the trajectory of new business development and technological progress within digital infrastructures [46]. Fig. 5 demonstrates architecture of the proposed method for load balancing.

To orchestrate an efficient load management paradigm within a network, particularly in environments with dense data exchange, a meticulous monitoring and analytical framework is imperative for handling inbound traffic across all network controllers. Initially, the controller serves as the vanguard, diligently monitoring traffic and subsequently facilitating the extraction of salient features. These features become instrumental for the sophisticated classification model, which, predicated on prior training, discerns and categorizes incoming data into established classes [47].

Post-classification, the network engages in nuanced traffic engineering procedures. This phase is critical as packets are judiciously directed to the appropriate controllers; each specifically assigned to manage certain traffic types [48]. Consequent to this stratified processing, data transmission to the intended destination addresses ensues, adhering strictly to a hierarchy of priority and queuing policies pre-configured within the controllers and network switches [49].

This systematic approach to traffic management and load balancing is quintessential to maintaining not only functional efficiency but also optimal network integrity and service quality. By integrating intelligent feature extraction and leveraging trained classification models, the methodology underscores the strategic employment of advanced analytical techniques in contemporary network management. This complex choreography of data handling and traffic distribution represents a significant stride toward more resilient, self-regulating, and intelligent digital communication infrastructures.

Within the extensive realm of Artificial Neural Networks (ANN), as depicted in Fig. 6, resides the Back Propagation (BP) method, a cornerstone technique characterized by its structured, multi-layered feed-forward networks. These networks undergo rigorous training through a distinctive error correction method, solidifying BP's status as a prevalent neural network paradigm. BP's utility shines in its capacity to establish and preserve numerous relational mappings within an input-output construct, eliminating the prerequisite of pre-defining the mathematical equations governing these connections.

The essence of its training methodology hinges on a gradient descent strategy. Here, the backpropagation mechanism plays a crucial role in regulating the neural network's synaptic weights and threshold parameters, striving for the minimalization of the cumulative squared error. In this context, the Back Propagation Neural Network (BPNN) becomes instrumental in the network's learning phase. Each unit within the neural assembly is interconnected, featuring distinct weights that interact with their computational algorithms.

Fig. 5. Architecture of the proposed method.

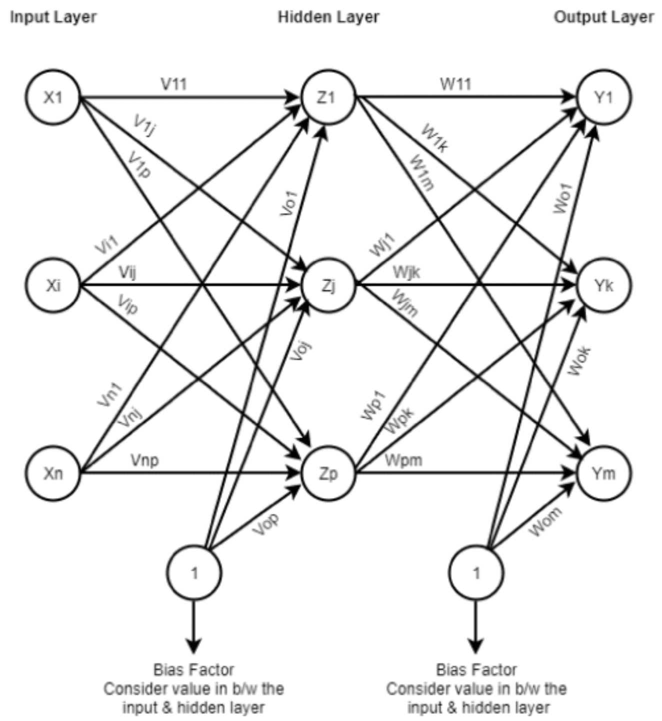

Fig. 6. Neural network architecture for load balancing problem.

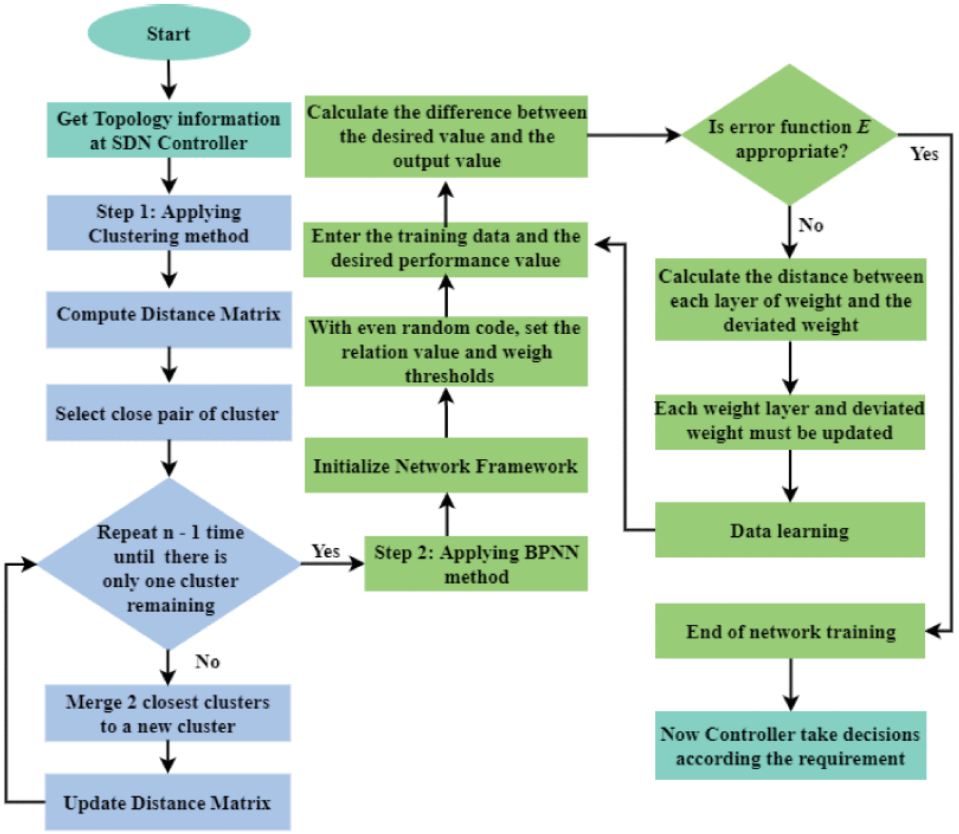
The BP method facilitates the derivation of statistical frameworks from voluminous data conglomerates, mimicking the operational intricacies of the human neurological system. In the realm of neural network education, Back Propagation is indispensable. It employs a refinement process that incrementally ameliorates the error quotient, drawing upon historical data from preceding cycles. This progressive adjustment of synaptic weights contributes to diminishing error margins, thereby bolstering the system's precision and enhancing its ability to generalize, a process detailed further in the subsequent procedure section.

- Initialization of weights
- Feed-forward step
- Back Propagation of errors
- Update of weights and bias

Fig. 7 illustrates the progression of the suggested strategy, commencing with the assimilation of topology data, represented through graph topology. This approach unfolds in two primary phases. Initially, a clustering method is employed within the Software-Defined Networking (SDN) framework, executed with precision to avoid congestion, accommodating various service types and data specifications. This technique hinges on a proximity-based criterion, persisting until a singular, consolidated cluster emerges. Upon the culmination of clustering, the strategy advances to the next stage, invoking the Back Propagation Neural Network (BPNN) for network training, thereby refining error margins using historical iterative data.



Start
Get Topology information at SDN Controller
Step 1: Applying Clustering method
Compute Distance Matrix
Select close pair of cluster
Repeat n - 1 time until there is only one cluster remaining
Yes
No
Merge 2 closest clusters to a new cluster
Update Distance Matrix
Step 2: Applying BPNN method
Initialize Network Framework
With even random code, set the relation value and weigh thresholds
Enter the training data and the desired performance value
Calculate the difference between the desired value and the output value
Is error function E appropriate?
Yes
No
Calculate the distance between each layer of weight and the deviated weight
Each weight layer and deviated weight must be updated
Data learning
End of network training
Now Controller take decisions according the requirement

Fig. 7. Flowchart of the proposed model.

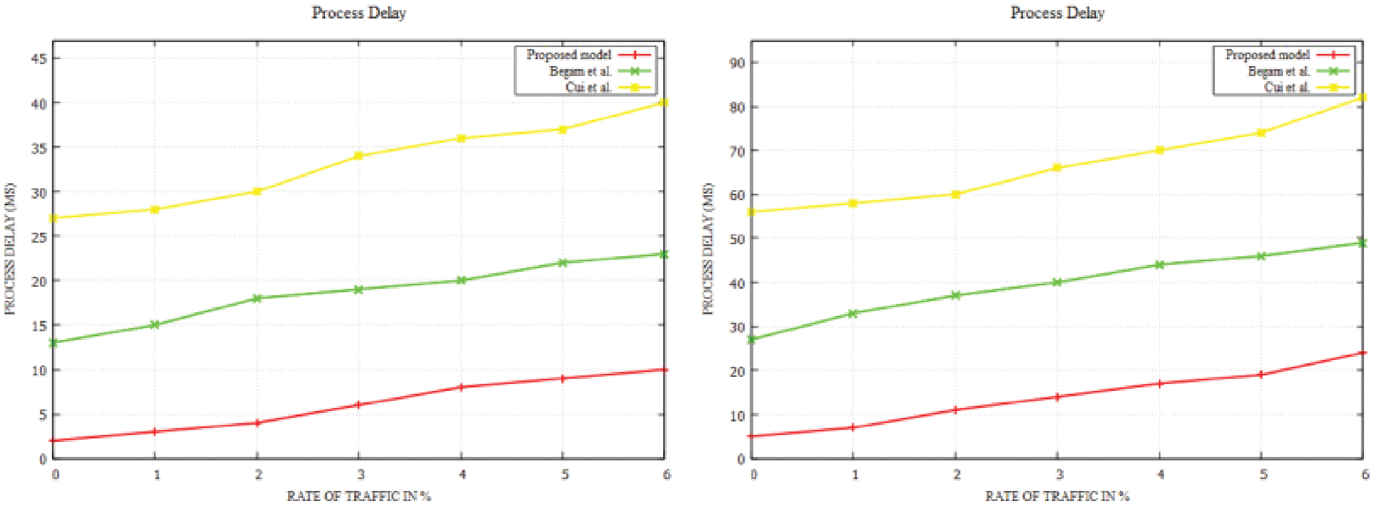
The BPNN process revolves around four pivotal stages: the establishment of initial synaptic weights, the execution of a unidirectional data transfer, the reverse transmission of computational discrepancies, and the subsequent recalibration of weights and biases. Within this structure, the controller operates as the network's central processing unit, retaining comprehensive records of the network topology. This information is paramount for the controller to make informed, context-aware decisions regarding traffic routing, optimizing overall network efficiency.

IV. Experimental Results

The time required for a node to process a packet is defined as the nodal processing delay (dproc), encompassing activities such as error identification, packet inspection, and determining the subsequent nodal link based on the packet's intended destination. Despite the intricate nature of these tasks, the time attributed to nodal processing is typically marginal when contrasted with other elements contributing to overall delay. Within a simulated environment on Mininet, the SDN controller's processing capacity is assessed to determine the efficacy of the introduced solution, employing a clustering approach. Fig. 8 delineates a comparative analysis of processing delays, referencing studies by Krishnan et al. [50] and Cui et al. [51].

In scenarios where network traffic maintains a lower threshold, processing delays are scarcely a concern for SDN infrastructures. However, under conditions of escalating data influx and heightened network activity, the advanced solution sustains a processing time below 1ms for the majority of the operational duration. In contrast, the methodologies adopted by Krishnan et al. [50] and Cui et al. [51] encounter extended latencies, attributable to the protracted journey through multiple nodes with finite processing capacities, compounded by substantial data reception rates.

As depicted in Fig. 8, the innovative method prioritizes packets by analyzing traffic patterns. The successful delivery of packets to their intended node is facilitated through a technique known as incremental averaging. Notably, transmission latency maintains a consistent trajectory, avoiding exponential escalation over time, as evidenced by the proposed solution. This stability in information transfer delay marks an improvement over conventional strategies, underscoring the enhanced efficiency of the proposed system.



(a) (b)

Fig. 8. Comparison of network delays.

Fig. 9 demonstrates results of machine learning methods in load balancing problem. The analysis of the results indicates a pronounced underperformance of the K-means clustering algorithm across all evaluated metrics. One primary reason for this inefficiency is the inherent predisposition of K-means towards categorizing data into spherical, homogeneously-sized clusters. This characteristic poses a significant limitation, particularly when applied to our dataset, which exhibits non-linear characteristics and inherently encompasses clusters of varying sizes. Consequently, in the context of multi-class classification, K-means struggles to accurately interpret the essential configuration of the dataset, failing to delineate the boundaries between distinct classes effectively. This shortfall underscores the algorithm's inadequacy in managing complex data structures, highlighting the necessity for more sophisticated techniques that can adapt to the intricacies presented by non-linear, unevenly distributed data categories.

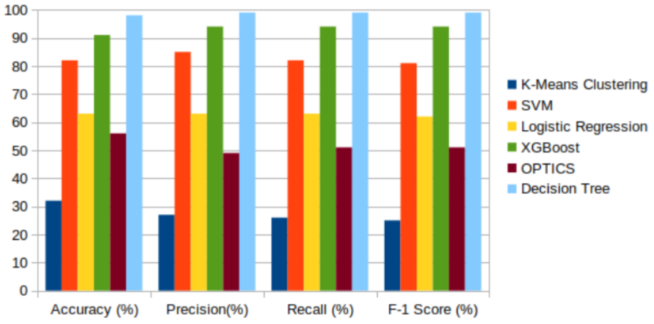


Fig. 9. Machine learning methods in load balancing using software defined network.

V. Discussion

In this research, we have ventured into a comprehensive exploration of integrating machine learning with software-defined networking (SDN) to enhance load balancing in data center networks (DCNs). The discussion section will delve into the critical reflections on the findings, implications, limitations, and prospective directions for future research.

A. Reflection on Main Findings

The crux of our research was the efficacious application of machine learning algorithms to inform SDN controllers, thereby optimizing load balancing strategies in DCNs. The study's pivotal revelation was that machine learning, particularly the backpropagation neural network model, facilitated an astute understanding of traffic patterns and network loads. These insights were instrumental in preemptively distributing network traffic, reducing bottlenecks, and significantly curtailing delay times [52].

Comparative analyses with traditional load balancing methodologies underscored the superiority of the proposed solution. Notably, where legacy systems [53] struggled with high data transfer latencies due to convoluted nodal paths and elevated data arrival rates, our model demonstrated resilience. The integration of machine learning allowed the system to anticipate network congestions and reroute traffic dynamically, ensuring optimal data fluidity [54].

The real-world applicability of our approach was further validated through simulated assessments, where it consistently maintained processing delays below the critical 1ms threshold, even under substantial network stress. This is a non-trivial achievement, considering the burgeoning data demands on modern DCNs [55].

B. Implications

Our research's implications are manifold, impacting network management paradigms, data center operational efficiencies, and broader technological spheres, such as 5G networks and IoT infrastructures.

1) Paradigm shift in network management: By harnessing machine learning's predictive capabilities, network administrators can transition from reactive approaches to a more proactive management style. The system's ability to foresee potential network spikes and adaptively manage loads alters the fundamental modus operandi of network management [56].

2) Operational efficiency: The evident reduction in processing and queuing delays signifies that data centers can handle larger data volumes with the current infrastructure. This efficiency does not only translate to cost savings but also minimizes the need for frequent hardware scaling, thus echoing sustainability in resource utilization [57].

3) Advancing 5G and IoT: With 5G and IoT heralding an era of unprecedented interconnectivity and data exchange, the demand on networks is astronomical. Our solution's demonstrated efficacy in maintaining low latencies is cardinal in these contexts, where a millisecond's delay can derail mission-critical applications [58].

C. Limitations

Despite its promise, our study is not without limitations. First, the dependency on historical data for machine learning models raises concerns about the system's adaptability to real-time anomalies not represented in past patterns. This limitation beckons further exploration into adaptive learning models that evolve with real-time network conditions [59].

Secondly, the simulated testing environment, though meticulously curated, cannot encapsulate all the unpredictable variables of a live DCN. Therefore, while the results are encouraging, there might be unforeseen challenges when implementing the solution in a full-scale operational data center [60].

Lastly, concerns about cybersecurity in SDNs, especially with the integration of machine learning, remain marginally addressed. The open interfaces and programmability, though central to SDN’s versatility, also introduce vulnerabilities that cybercriminals could exploit [61].

D. Future Directions

In light of the aforementioned limitations, future research should aim at developing more robust machine learning algorithms capable of real-time learning. Such evolution would enhance the system's responsiveness to immediate network conditions, thus improving reliability [62].

Further, transitioning from a controlled simulated environment to pilot testing in actual data centers should be a priority. Real-world applications will provide invaluable insights and practical challenges, refining the solution for commercial readiness [63].

Additionally, there is a pressing need to explore integrated cybersecurity frameworks that safeguard SDNs while preserving their flexibility. Collaborative efforts towards creating standardized security protocols for SDNs, particularly in DCNs employing machine learning, are imperative [64].

In conclusion, this study marks a significant stride towards revolutionizing load balancing in DCNs through the integration of machine learning in SDN. While the findings and performance metrics underscore its potential, there is an evident path ahead filled with rigorous testing, enhancements, and wider collaborative engagement for standardization and security. Embracing these challenges is pivotal for the fruition of this innovative convergence and its subsequent contribution to the future of networking and data management.

VI. Conclusion

The journey of this research ventured through the intricate realms of data center networks (DCNs), seeking innovative resolutions to the perennial challenges of load balancing, a critical determinant of network performance and reliability. Through the integration of machine learning (ML) algorithms with the transformative architecture of software-defined networking (SDN), this study pioneered an approach with the potential to redefine operational efficiencies within DCNs.

The synthesis of ML into the SDN framework facilitated an unprecedented level of network adaptability and intelligence. Where traditional network infrastructures falter under dynamic traffic demands and complex application requirements, the proposed model, fortified by backpropagation neural network methodologies, demonstrated notable competencies in preempting traffic inconsistencies, optimizing resource allocations, and substantially mitigating data transfer delays. These achievements were not merely theoretical postulations but were empirically validated through rigorous simulations juxtaposed against established benchmarks.

However, beyond these technical triumphs, this research underscores a broader, paradigmatic shift in network management. It advocates for a transition from static, hardware-dependent operations to agile, software-centric mechanisms that leverage predictive analytics, adapt in real-time, and make data-driven decisions. Such an evolution holds profound implications not just for the efficiency and resilience of DCNs, but also for the burgeoning spheres of Internet of Things (IoT) and 5G technologies, where network demands are escalating exponentially.

Conclusively, while this investigation lays foundational groundwork, it also casts light on several avenues necessitating further exploration. Real-world implementation trials, adaptive machine learning models, comprehensive cybersecurity protocols, and standardization across the burgeoning SDN landscape are imperative follow-ups. This research, therefore, serves not as a terminus, but as a launchpad for continued innovation, inviting academia, industry, and regulatory bodies to collectively shepherd this technological advancement from its current nascent stage to a global, operational reality. The future of DCNs, and indeed, the digital infrastructure at large, hinges on such pioneering endeavors, marking the importance and urgency of ongoing and future research in this domain.

Abstract*—Addressing the challenge of ensuring a comfortable indoor environment in both commercial and residential buildings through the use of heating, ventilation, and air conditioning (HVAC) systems is a critical issue. This challenge is intricately connected to the development of sophisticated multi-channel controllers to regulate temperature and humidity effectively. This academic discussion initially focuses on the development and examination of a complex, interactive, nonlinear mathematical model that encapsulates the ideal parameters for temperature and humidity to achieve the desired comfort levels. The paper then progresses to explore various methodologies in the design of temperature and humidity control systems. It delves into the traditional Proportional-Integral-Derivative (PID) controllers, a mainstay in the industry, and extends to more advanced iterations. These include the integration of PID controllers with distinct decoupled controllers and the innovative combination of PID controllers with self-adjusting parameters, which are informed by the principles of fuzzy logic. This combination is particularly significant for the processes of heating and humidification. Subsequently, the paper presents the results obtained from simulations conducted on a proposed fuzzy-PID controller using Matlab, a widely used computational tool. These simulations are crucial in evaluating the efficacy of the controller design. Additionally, the paper offers an analysis of experimental data collected over a six-month period. This data is instrumental in assessing the real-world performance of the proposed system, providing valuable insights into its practical applicability and effectiveness in managing indoor climate conditions. In summary, this comprehensive study not only lays the groundwork for an interactive model for climate control but also compares various controller designs, culminating in the proposal and evaluation of an advanced fuzzy-PID controller. This work stands as a significant contribution to the ongoing efforts to enhance indoor climate control in buildings.

***Keywords*—HVAC; Fuzzy logic; energy management; comfort management; smart home**

I. INTRODUCTION

The quality of the air environment within buildings, governed by a myriad of factors both external (exogenous) and internal (endogenous), is a critical determinant of the conditions under which people live and work, their health, and their overall comfort. The creation of a 'healthy' and comfortable indoor air environment is a complex and costly endeavor, requiring the deployment of advanced, multifunctional engineering systems [1]. The financial implications are significant; for example, eliminating just 1 kW of surplus heat to regulate air temperature within a building can cost between 300 and 600 USD [2]. Traditionally, comfort in indoor environments has been associated with the management of three primary microclimate variables: air temperature (with a precision of ± 1 °C), the temperature of surrounding surfaces, and relative humidity (RH) (with a precision of ± 7%) [3].

Given these factors, the quality and comfort of indoor environments have emerged as topics of growing importance. This has led to the widespread adoption of heating, ventilation, and air conditioning (HVAC) systems in numerous buildings. A key challenge in this area is reducing the energy consumption of HVAC systems while still maintaining an optimal level of comfort – a problem that remains incompletely solved. The International Energy Agency reports that HVAC systems account for approximately 40% of the total energy consumption in residential and commercial buildings [4].

Historically, HVAC systems have been limited in their ability to ensure comprehensive comfort, typically focusing on maintaining environmental conditions within certain thresholds. The optimization of comfort thus relies heavily on the customization of these systems to individual user needs. Conventional approaches have primarily utilized on-off and Proportional Integral Derivative (PID) controllers, designed to minimize the discrepancy between a fixed setpoint and the variable being regulated [5, 6].

Recent research, however, has redefined HVAC systems as multiple-input multiple-output (MIMO) problems, given their operation with interrelated variables to produce a range of output values [7, 8]. These systems are influenced by a variety of uncertain parameters, such as user preferences, occupant activities, and external environmental factors, which can alter their standard operations. Consequently, HVAC control issues are increasingly viewed as multi-criteria tasks, necessitating complex analytical expressions for characterization [9, 10].

While conventional PID controllers offer reasonable solutions, they fall short in fully managing the unpredictability inherent in the dynamics of HVAC systems. These dynamics can be more aptly described using linguistic variables and rules [11, 12]. As an alternative, Fuzzy Logic Controllers (FLC) have gained attention. FLCs do not require mathematical modeling [13] and are capable of handling various criteria, representing the dynamics of HVAC systems based on a knowledge-driven approach. Their efficiency and reduced power consumption, compared to PID controllers, have been demonstrated in recent studies [14, 15].

This paper is structured as follows: Section II reviews related literature, focusing on comfort parameters, control techniques, current challenges in control methods, and future perspectives. Section III outlines the problem statement. Section IV introduces a mathematical model for indoor air temperature and humidity. Section V delves into the design process of intelligent PID controllers for controlling indoor temperature and humidity, explaining proposed techniques for each controlling parameter. Section VI presents simulation results and findings from experiments conducted in our laboratory as part of this study. Section VII and Section VIII presents the discussion and conclusion respectively.

II. Related Works

The Related Works section of this paper provides a comprehensive overview of the existing literature pertaining to the field of heating, ventilation, and air conditioning (HVAC) systems, focusing particularly on the advancement of control techniques and the ongoing quest for optimization of indoor environment quality and comfort. This review is structured to encapsulate the broad spectrum of research conducted in this domain, drawing on a wide range of studies and analyses from diverse sources.

A. Microclimate Control and Comfort Parameters

The domain of microclimate control within architectural spaces necessitates a nuanced understanding of the variables that significantly influence human comfort and well-being. Contemporary research within this sphere has primarily concentrated on identifying and comprehensively understanding the critical elements contributing to human comfort, such as air temperature, humidity, and air quality [17, 18]. These studies underscore the imperative of maintaining precise control over these parameters. This necessity stems not solely from the perspective of ensuring comfort but also from the vantage point of health implications. Inadequate management of air quality, temperature, and humidity has been linked to a range of health complications, thereby highlighting the health-centric dimension of microclimate control [19, 20].

Further extending this discourse, recent scholarly investigations have ventured into examining the subjective aspects of comfort. The subjective perception of comfort, being inherently individualistic and variable, presents a challenge in its quantification and subsequent integration into control systems. These studies have embarked on exploring methodologies to effectively measure and incorporate this subjective element of comfort into the operational frameworks of microclimate control systems [21, 22]. This line of inquiry marks a significant shift from traditional objective measures, paving the way for a more holistic and user-centric approach in the design and management of indoor environmental conditions.

In summation, the body of research in microclimate control and comfort parameters is pivoting towards a more inclusive understanding that encapsulates both the objective and subjective facets of human comfort. This paradigm shift is instrumental in fostering environments that are not only technically sound but also attuned to the nuanced preferences and health requirements of individuals.

B. Energy Efficiency in HVAC Systems

In the realm of Heating, Ventilation, and Air Conditioning (HVAC) systems, a considerable segment of academic research is dedicated to the exploration of energy efficiency. This focus aligns with the broader environmental objectives of promoting sustainability and minimizing carbon emissions. Investigations in this field have been directed towards identifying and implementing strategies to curtail energy consumption in the operation of HVAC systems [23, 24]. Empirical studies have elucidated that enhancements in the energy efficiency of HVAC systems can significantly reduce the overall energy expenditure of buildings. This is particularly pivotal considering the substantial share of energy consumption attributed to HVAC operations [25, 26]. Additionally, the literature indicates a burgeoning interest in adopting progressive approaches towards energy efficiency. These include, but are not limited to, the integration of renewable energy sources and the advancement of smart grid technologies, thereby providing a comprehensive framework for energy optimization in HVAC systems [27, 28]. Such explorations represent a crucial step towards aligning HVAC system operations with the principles of environmental stewardship and sustainable development.

C. Control Techniques in HVAC Systems

The scholarly discourse on Heating, Ventilation, and Air Conditioning (HVAC) systems has been notably enriched by the evolution of control techniques. Central to this discourse is the critical examination of traditional control methodologies, including on-off and Proportional-Integral-Derivative (PID) controllers. These conventional methods have undergone thorough scrutiny, with research primarily concentrated on identifying their limitations and exploring potential enhancements [29, 30]. A pivotal development in this field has been the introduction and subsequent adoption of advanced control techniques, notably Fuzzy Logic Controllers (FLC). Research in this area underscores the superiority of FLCs in managing the intricate and frequently unpredictable dynamics characteristic of HVAC systems [31, 32]. Comparative studies elucidating the distinctions between traditional PID controllers and FLCs have been instrumental in highlighting the strengths of the latter. Notably, FLCs demonstrate enhanced proficiency in dealing with systems that involve multiple variables and are subject to a high degree of uncertainty [33, 34]. This body of research signifies a meaningful shift towards more sophisticated and adaptable control mechanisms in HVAC system management.

D. Modeling and Simulation of HVAC Systems

In the scholarly examination of Heating, Ventilation, and Air Conditioning (HVAC) systems, the aspects of modeling and simulation occupy a position of critical importance. Precise and accurate modeling is fundamental to the comprehensive understanding of HVAC system behavior, which in turn is crucial for the development of efficacious control strategies. The literature in this domain showcases a spectrum of modeling techniques, ranging from the relatively straightforward linear models to more intricate and sophisticated nonlinear and dynamic models [35, 36]. To corroborate the validity and effectiveness of these models, simulation tools like Matlab have been extensively utilized. These tools offer a secure and economically viable avenue for assessing the performance of diverse control strategies across a variety of operational scenarios [37, 38].

Concurrently, the influence of user preferences and external environmental factors on the performance of HVAC systems represents a recurring subject in academic research. Studies have consistently demonstrated that the behaviors and preferences of users can exert a significant impact on the effectiveness of HVAC systems [39, 40]. Moreover, external variables, including meteorological conditions and patterns of building occupancy, are also recognized as playing a pivotal role in determining system performance. Investigations into these factors have been comprehensive and varied [41, 42]. These findings highlight the imperative for HVAC systems to not merely embody technical sophistication but also exhibit adaptability to the dynamic and evolving needs of users, as well as to the fluctuating external environmental conditions. This dual focus on technical advancement and adaptability is crucial for the design and implementation of HVAC systems that are both efficient and responsive to the nuanced requirements of their operational contexts.

E. Challenges and Future Directions

In the concluding segment of the literature review, attention is directed towards the challenges currently confronting the field of Heating, Ventilation, and Air Conditioning (HVAC) systems, alongside prospective avenues for future scholarly inquiry. A primary challenge that emerges from these studies is the incorporation of advanced control techniques into the existing framework of HVAC infrastructure. This integration process poses considerable technical complexities and demands innovative solutions [43]. Furthermore, the literature points to the necessity of developing more comprehensive and intuitive interfaces for the monitoring and control of HVAC systems. Such interfaces are essential to enhance user engagement and system efficiency [44].

Looking forward, the trajectory of research in this domain is anticipated to concentrate on augmenting the adaptability and intelligence of HVAC systems. A significant emphasis is being placed on the integration of cutting-edge technologies such as artificial intelligence (AI) and machine learning (ML). These technologies hold the promise of revolutionizing HVAC systems, making them more responsive and efficient [45]. The integration of AI and ML is expected to enable HVAC systems to learn from and adapt to changing environmental conditions and user preferences, thereby optimizing performance and energy efficiency.

In summation, the corpus of literature surrounding HVAC systems is comprehensive and multifaceted, encompassing a diverse range of topics from basic considerations of microclimate control and comfort parameters to the exploration of advanced control methodologies and the identification of future research directions. This extensive body of work lays a robust foundation for ongoing studies and highlights the imperative for continued research and development in this field. The ultimate goal is to realize HVAC systems that are not only more efficient and adaptable but also more user-friendly, thereby aligning with the evolving needs and expectations of contemporary society.

III. Problem Statement

This research endeavor is primarily focused on devising control strategies that amalgamate traditional and intelligent control technologies to optimize indoor environment quality. This includes the regulation of indoor air temperature and humidity, achieved through a blend of computational modeling and empirical investigation. The overarching objective of this strategy is to explore and demonstrate avenues for enhancing the comfort of occupants within built environments. To this end, the development and analysis of three distinct controllers are undertaken. These controllers are designed to assess the efficacy of newly proposed control mechanisms in managing indoor environmental quality. Additionally, this study seeks to evaluate the feasibility and effectiveness of employing intricate control strategies that are an integration of various control techniques.

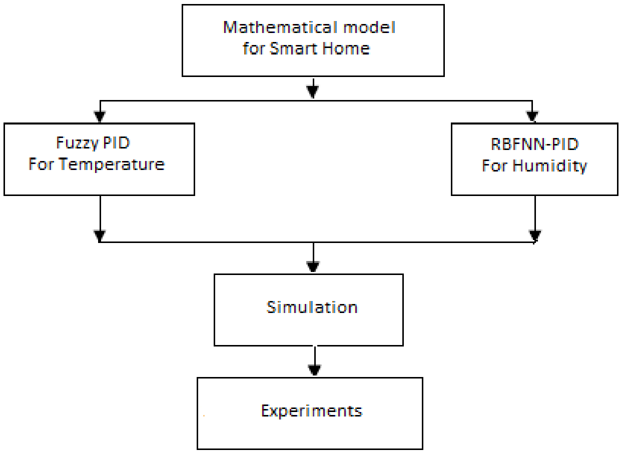

Fig. 1. Stages of designing an intelligent PID control system.

The methodology and progression of this research are methodically outlined in Fig. 1. This breakdown delineates the various stages of the study, providing a clear and structured roadmap for the investigation. Each phase of the research is designed to build upon the findings of the preceding stages, thereby ensuring a comprehensive and systematic exploration of the control strategies under consideration. This approach allows for a thorough examination of the potential and limitations of both conventional and intelligent control technologies in the context of indoor environment quality control, with a specific focus on enhancing occupant comfort in built environments.

IV. Mathematical Model

This study investigates a typical room outfitted with a foundational Heating, Ventilation, and Air Conditioning (HVAC) system, as depicted in Fig. 2. The system is equipped with a heater using hot/cold water and a humidifier employing steam. The process begins with the modulation of the mixed air temperature post-filtration, wherein the external air is either heated or cooled via a heating/cooling coil. Following this, the external air may undergo humidification through a steam humidifier before being circulated into the room by a supply fan. Concurrently, exhaust air is expelled from the room by a return fan.

A critical component of this system is the heating/cooling coil, which imparts thermal-humid energy, denoted as P, to the indoor air. This energy transfer is modulated by varying the flow rate of hot/cold water (Fp) through the Hot Water Return/Cooling Heat Recovery (HWR/CHR) control valve. Similarly, the steam humidifier contributes thermal-humid energy, represented as Q, to the indoor air by adjusting the steam flow rate (Fq) via the control steam valve. The system's temperature and humidity are regulated by manipulating the positions of the hot/cold water and steam valves, thereby altering the flow rates Fp and Fq in accordance with specific equations [46].

The indoor temperature is influenced by multiple factors, including the initial indoor microclimate air temperature, outdoor temperature, the volume of the premises, the efficiency of the heater or air conditioner, and the heat loss through the walls. Based on the principles of energy conservation, the indoor air temperature can be mathematically expressed, taking into account these variables and their interplay as depicted in Fig. 2. This expression is central to understanding the dynamics of indoor temperature regulation and forms the basis for further exploration and analysis in this study.

$$\rho_a V_{indoor} C_p \frac{dT_{indoor}(\tau)}{d\tau} = a_p F_p(t) - U_w A_w \left[T_{indoor}(\tau) - T_{outdoor}(\tau)\right] \tag{1}$$

Here, ρ_a air density, V_{indoor} volume of air into the room, C_p heat capacity of air, T_{indoor} indoor air temperature, τ time, a_p channel coefficient, F_p water flowrate into heating/cooling system, $T_{outdoor}$ outdoor air temperature, A_w square of the wall, U_w overall heat transfer coefficient for the wall.

To simplify Laplace transforms as presented in Eq. (3), the process typically involves converting the time-domain equation into its corresponding s-domain representation. This conversion facilitates the analysis of systems, particularly in the context of control systems and differential equations. The Laplace transform essentially converts differential equations, which can be complex to solve in the time domain, into algebraic equations in the s-domain, which are simpler to manipulate and solve.

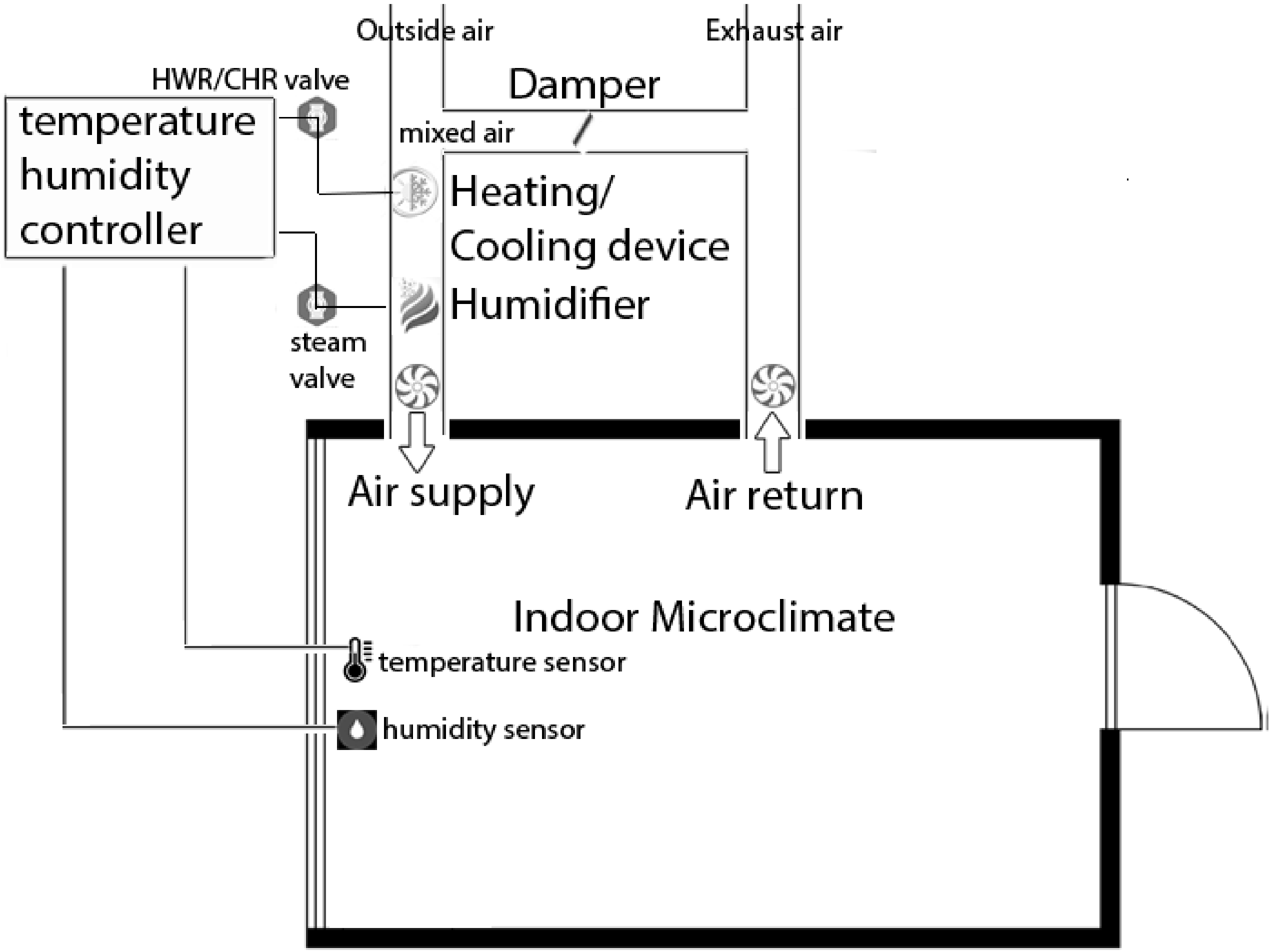

Fig. 2. Schematic diagram of indoor air temperature and humidity control processes in HVAC system.

In the context of the specific Eq. (1) you're referring to, the Laplace transform would take each term of the equation and convert it into its Laplace form. This involves identifying the Laplace transform of each component of the equation – for instance, functions of time, derivatives, and integrals – and representing them in terms of 's', which is the complex frequency parameter in the Laplace domain.

$$\left[\frac{\rho_a V_{indoor} C_p}{U_W A_W} s + 1\right] \cdot T_{indoor}(s) = \frac{a_P}{U_W A_W} F_P(s) + T_{outdoor}(s) \tag{2}$$

Under the assumption that the indoor temperature is not influenced by the outdoor temperature and considering the time delay inherent in the heat transfer process within an indoor environment, the simplification of Eq. (4) can be approached by focusing on the internal dynamics of the system while disregarding external thermal influences.

$$G_{11} = \frac{T_p(s)}{F_p(s)} = \frac{k_{tp} e^{-q_{tp} s}}{t_{tp} s + 1} \tag{3}$$

When considering the relationship between temperature and humidity in an indoor environment, it's essential to acknowledge that changes in humidity can significantly affect air temperature. The operation of a humidifier, by adding moisture to the air, can influence the thermal characteristics of the space. This is due to the latent heat exchange involved in the process of humidification, which can either absorb or release heat, thereby affecting the overall air temperature.

Incorporating the effect of the humidifier on the temperature, typically represented by the temperature Tq affected by the humidification process, the indoor air temperature can be modeled taking into account both the direct heating or cooling effect (through HVAC systems) and the indirect effect of humidification. The relationship can be expressed in a combined form where the temperature equation accounts for the additional variable Tq.

The modified equation would typically include terms representing the heat added or removed by the HVAC system and the change in enthalpy due to humidification. The equation might take a form similar to:

$$G_{12} = \frac{T_q(s)}{F_q(s)} = \frac{k_{tq} e^{-q_{tq} s}}{t_{tq} s + 1} \tag{4}$$

Where, G_{12} Laplace transfer function, F_q flowrate of steam, $t_{tq} = \frac{V_{indoor}}{f_a}$, $k_{tq} = \frac{a_q a_t}{f_a r_a E_p}$.

V. Fuzzy Rules for HVAC Control

In the pursuit of maintaining internal thermal comfort within a specified environment, a controller equipped with fuzzy inference capabilities has been developed. This controller is tasked with calculating the necessary power to sustain the desired thermal conditions. The operational mechanism of this fuzzy controller is based on the inputs of error and error rate of change, which are pivotal in guiding its decision-making process.

The concept of 'error' in this context refers to the deviation between the desired temperature setpoint and the actual temperature observed within the environment, represented as e (measured in degrees Celsius, °C). This error is a critical factor in determining the necessary adjustments required to achieve thermal comfort. Additionally, the controller considers the rate of change of this error over time, which is essentially the first derivative of the temperature variation within a given computational cycle. This rate of change is measured in °C/min and provides insight into the dynamic behavior of the temperature within the environment [47].

The primary challenge addressed by this controller is the accurate determination of the temperature output that should be relayed to the digital-to-analog converter regulator. This regulator then executes the necessary adjustments to align the actual temperature with the desired setpoint. The input variables for this regulator include the aforementioned error e and the rate of change of this error. By leveraging these inputs, the fuzzy inference controller can make nuanced decisions that account for both the current state and the trajectory of the temperature, thereby ensuring efficient and responsive control for maintaining internal thermal comfort.

$$\Delta e = T_{desired}(t) - T_{current}(t) \tag{5}$$

where, $T_{desired}(t)$, $T_{current}(t)$ are the desired and current temperatures in °C and t is the time in minutes.

The rate of temperature change in a given environment, particularly when cooling or heating is involved, is intrinsically linked to the magnitude of the temperature difference between the desired setpoint and the current temperature. This relationship is a fundamental principle in thermodynamics and heating, ventilation, and air conditioning (HVAC) system dynamics.

Mathematically, the rate of temperature change can be expressed through a formula that incorporates the temperature difference as a key variable. The formula typically takes into account not only the temperature difference but also the efficiency and capacity of the heating or cooling system, the thermal properties of the space (like insulation and volume), and external factors such as ambient temperature.

The rate of temperature change (ΔT/Δt), where ΔT is the temperature difference and Δt is the time interval, can be represented as:

$$\Delta e = \frac{e(t_1) - e(t_2)}{t_1 - t_2} \tag{6}$$

In the development of a fuzzy logic controller for temperature regulation, the concept of linguistic fuzzy variables becomes paramount. These variables allow for the characterization of the system's state in a manner that is akin to human reasoning, which is especially useful in systems where precision and complex calculations are less feasible or desirable. In this context, the linguistic fuzzy variables are designed to describe the temperature difference (e) and the rate of temperature change.

The construction of membership functions for these variables is a critical step in the fuzzy logic design process. Membership functions define how each point in the input space is mapped to a membership value (or degree of membership) between 0 and 1. For this controller, two distinct membership functions are formulated:

Temperature Difference (e): This function maps the temperature difference (e) within the range of -6 to +6 °C. The linguistic identifiers for this membership function include:

Large Positive Deviation (LPD)

Average Positive Deviation (APD)

Small Positive Deviation (SPD)

Zero Deviation (Z)

Small Negative Deviation (SND)

Average Negative Deviation (AND)

Large Negative Deviation (LND)

Rate of Temperature Change: This function represents the rate of temperature change within the range of -6 to +6 °C/min. The same linguistic identifiers (LPD, APD, SPD, Z, SND, AND, LND) are used to describe the rate of change.

These membership functions, as visualized in Fig. 3 for the temperature difference and Fig. 3 for the rate of temperature change, enable the fuzzy logic controller to interpret and respond to various states of the indoor environment. The output parameter value, which is the result of the joint effect of these two membership functions, is determined by the control logic programmed into the fuzzy logic controller. This logic dictates how the controller responds to different combinations of temperature difference and rate of change, guiding the adjustments needed to achieve and maintain the target indoor temperature.

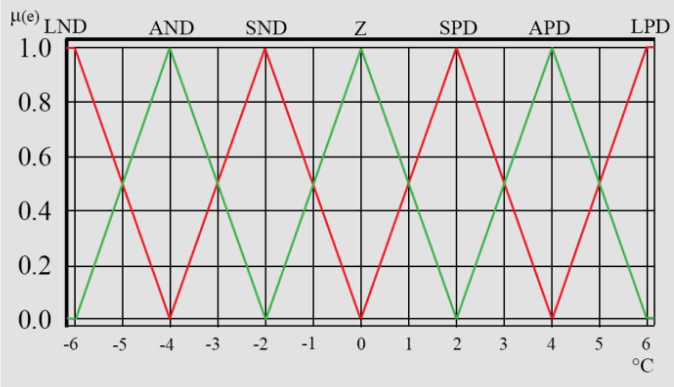

Fig. 3. Linguistic membership functions by the input parameter.

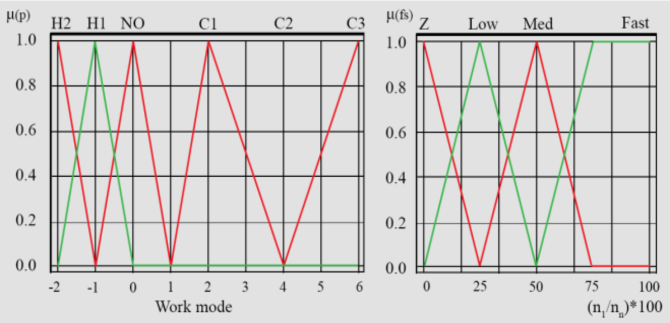

Fig. 4. Linguistic membership functions by output parameter.

Utilizing the established membership functions, as delineated in Fig. 4, the optimal operational mode for the heating and cooling systems within an indoor environment can be determined through fuzzy logic control. This control strategy employs a set of fuzzy variables, each with specific identifiers to represent different levels of heating and cooling required. These variables and their respective identifiers are:

Utilizing the established membership functions, as delineated in Fig. 4, the optimal operational mode for the heating and cooling systems within an indoor environment can be determined through fuzzy logic control. This control strategy employs a set of fuzzy variables, each with specific identifiers to represent different levels of heating and cooling required. These variables and their respective identifiers are:

For Cooling:

Strong Cooling (C3)

Average Cooling (C2)

Slight Cooling (C1)

For Heating:

Heating 1 (H1)

Heating 2 (H2)

For Neutral State:

Without Changes (NO)

In a similar fashion, the control of the fan rotation speed is computed based on a rule base, as visualized in Fig. 4. The fuzzy variables for fan speed are identified as:

High (Fast)

Normal (Med)

Low (Low)

Zero (Z)

The output membership function, represented in Fig. 4, illustrates the processing rule employed in the fuzzy logic system. This rule aggregates the response signals to generate a comprehensive output command. The chosen function in this study is designed to provide an output encompassing two heating levels (H1, H2), three cooling levels (C1, C2, C3), and a normative level (NO). This approach allows for a nuanced response to varying thermal conditions, enabling the system to adaptively modulate the heating or cooling levels, as well as the fan speed, in accordance with the real-time requirements of the indoor environment.

The flexibility of the fuzzy logic control system lies in its ability to interpolate between these defined levels, potentially envisaging scenarios where additional heating or cooling levels could be implemented. This could involve settings that exceed the defined parameters of H2 for extra heating or provide cooling options that are more intense than the levels of C2 and C1, thus catering to a wide range of environmental conditions and occupant comfort preferences.

Table I in the study delineates the application of linguistic variables, which are derived from the process of fuzzification applied to the response signal. This fuzzification process is significantly guided by operator intuition, a crucial aspect in the fuzzy logic control system. The linguistic variables, as defined and used in the system, encapsulate the varying degrees of response required for temperature regulation within the indoor environment.

TABLE I. LINGUISTIC MEMBERSHIP FUNCTIONS BY OUTPUT PARAMETER

		Temperature difference (e)						
		LND	***AND***	***SND***	***Z***	***SPD***	***APD***	***LPD***
Rate of temperature change	**LND**	C3	C3	C2	C1	NO	NO	H1
		Fast	Fast	Med	Slow	Z	Z	Med

	- cold consumption (heat output)	

VI. EXPERIMENTAL RESULTS

In this segment, we present the modeling and simulation results for a fuzzy Proportional-Integral-Derivative (PID) controller, specifically applied to the task of temperature regulation. The scenario begins with the assumption that the initial temperature within a room is not at an optimal level, thus necessitating adjustment. Upon setting a target temperature, the controller initiates its operation to achieve this desired thermal state. For the purpose of simulating this process, a reference input signal, indicative of the temperature difference to be addressed, is employed. Let us consider a scenario where the temperature difference between the internal environment and the external medium is set at 5 °C. Consequently, a step signal, denoted as r(k)=5, is introduced at the initiation of the simulation (time = 0 t=0).

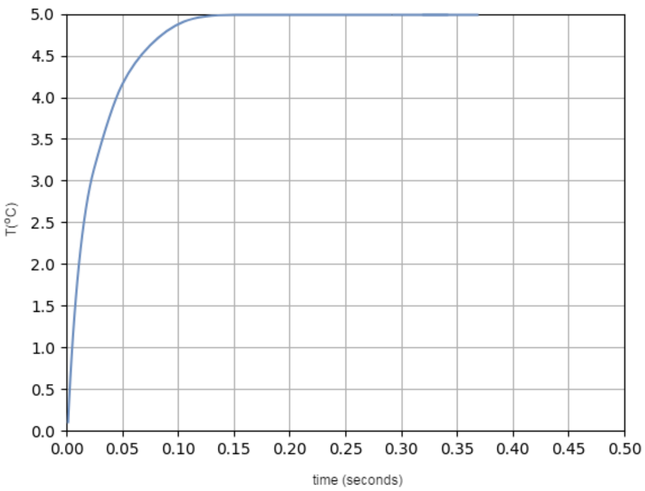

Fig. 5. System output response to step input.

The resultant simulation output of the temperature control system is depicted in Fig. 5. Analyzing the figure, we observe key performance metrics such as the time constant τ=0.033 seconds) and the settling time (t=0.092 seconds). These metrics are indicative of the controller's responsiveness to the input signal. Notably, the control system exhibits a rapid reaction time, characterized by a high rate of increase in response to the step change in temperature.

Additionally, the response dynamics of the system demonstrate the absence of overshoot, which is a desirable attribute in control systems, indicating precision and stability in reaching the target state without exceeding it. Moreover, the steady-state error is observed to be zero at the point where the control process stabilizes. This absence of steady-state error signifies that the proposed fuzzy PID control system effectively attains the desired temperature without deviation, thereby exemplifying its excellent performance. The system not only responds swiftly but also maintains control accuracy and stability, ensuring that the desired room temperature is achieved efficiently and reliably.

In the pursuit of maintaining internal thermal comfort within a specified environment, a controller equipped with fuzzy. Upon integrating these linguistic variables with the output membership function and subsequent de-fuzzification process, a distinct and actionable control signal is generated. This signal is pivotal in the fuzzy logic control system as it dictates the specific control actions to be undertaken by the heating and cooling systems. The control signal, in essence, represents the required level of heating or cooling, quantified in a range that typically includes values such as [−2, −1, 0, 1, 2, 3, ...]. These values correspond to the degrees of heating or cooling necessary to maintain or achieve the desired indoor temperature.

For instance, negative values (e.g., -2, -1) might indicate the need for cooling at various intensities, while positive values (e.g., 1, 2) suggest varying levels of heating. A zero value (0) would imply that no change is needed, maintaining the current state. The higher the absolute value, the more intense the heating or cooling action required.

The transformation of fuzzy inputs into a clear and quantifiable control signal through de-fuzzification is a crucial step, enabling the practical application of fuzzy logic theory in real-world control systems. This process ensures that the inherently vague and subjective nature of linguistic variables is translated into precise control actions, effectively bridging the gap between human-like reasoning and mechanical system control.

This figure elucidates how the controller's command, formulated based on the output data, is calculated and subsequently dispatched to the requisite device. This command is integral to modifying the air temperature within the room, showcasing the controller's active role in environmental regulation.

Further examination is presented in Fig. 6, which delineates the automatic adjustment process of the PID parameters. From these observations, it can be conclusively stated that the fuzzy PID control methodology effectively modifies the traditional PID controller parameters. This adaptability optimizes the control performance, ensuring that the system is responsive and stable, thereby achieving the desired environmental conditions with enhanced precision.

Fig. 6 presents a graphical depiction of the variations in carbon dioxide (CO2) levels over the course of a single working day in January 2021. This visualization provides insightful data on how human presence and activities in a workplace environment impact indoor air quality, particularly concerning CO2 concentration.

At the commencement of the working day, the CO2 concentration was observed to be low. However, a notable increase in the level of CO2 was recorded around 9:00 AM, corresponding with the arrival of employees at the workplace. This sharp rise in CO2 levels is attributable to the increased number of people, and hence, respiration rates within the enclosed space.

Subsequently, the efficiency of the air quality control system is evidenced as the CO2 levels are reduced to below 1000 parts per million (ppm). This reduction signifies the effective functioning of the ventilation or air purification system in managing and maintaining optimal air quality despite the increased occupancy.

An interesting variation is observed during the lunch hour, starting from 13:00 and lasting until 14:00. During this period, there was a discernible decrease in CO2 concentration to approximately 600 ppm. This reduction can be attributed to the opening of windows, allowing for enhanced natural ventilation and dilution of indoor CO2 levels. Post-lunch, as employees resumed their activities, the CO2 concentration experienced an immediate upsurge, eventually stabilizing at a comparatively steady level. This pattern suggests a consistent occupancy and activity level in the afternoon hours.

Finally, after 18:00, coinciding with the end of the workday and the departure of the employees, a decrease in CO2 levels was again observed. This trend aligns with the reduced human presence in the building, leading to lower respiration rates and thus, lower CO2 emission within the indoor environment. This diurnal pattern in CO2 levels highlights the direct correlation between human occupancy and indoor air quality, as well as the critical role of effective air quality management systems in maintaining a healthy indoor environment.

Monitoring the level of CO2 in indoor environments is crucial, distinctly different from the regulation of relative humidity and temperature, which are typically maintained within a specific range. The dynamics of CO2 concentration, particularly in scenarios where the air conditioning system is operational or when natural ventilation is enabled, are critical for indoor air quality (IAQ) management.

When the air conditioning is active or when the area is naturally ventilated (referred to as the air conditioning region being 'open' or 'free'), there is a noticeable decrease in CO2 levels within the room. This effect brings the CO2 concentration down to a lower, more desirable setting. In such scenarios, the CO2 levels inside the room fluctuate within a comparative range. However, it is important to note that standard deviation, a common statistical measure, may not adequately represent the effectiveness of air quality rate control strategies in managing CO2 levels.

Consequently, the internal temperature is often utilized as a more reliable parameter for assessing the performance of IAQ controllers. Fig. 7 in the study highlights the maximum monthly internal CO2 concentration observed. The findings indicate that the peak daily CO2 concentration does not exceed 1100 parts per million (ppm). This concentration level, while being the highest observed, is still within a range that is considered not harmful to human health and does not persist for prolonged durations.

Such insights are crucial in understanding the efficacy of IAQ control systems in maintaining CO2 concentrations at safe levels, ensuring a healthy indoor environment. This focus on CO2 levels, alongside temperature and humidity, forms a comprehensive approach to IAQ management, safeguarding both comfort and health within indoor spaces.

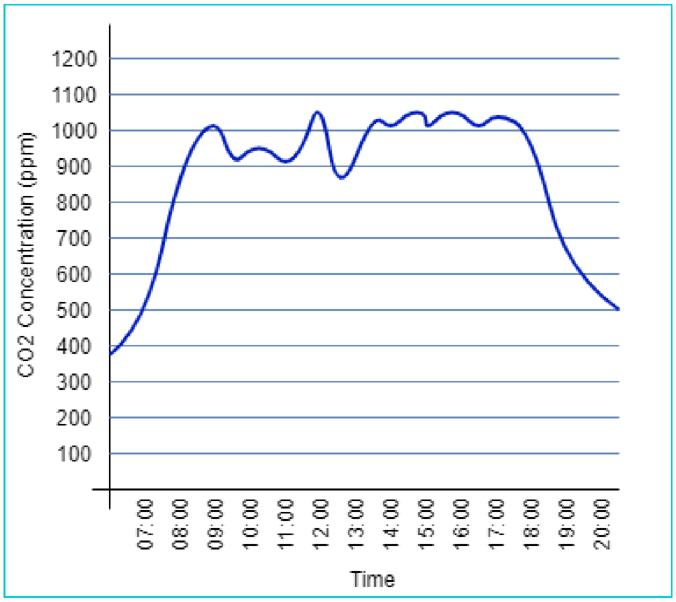

Fig. 6. Indoor CO2 concentration level.

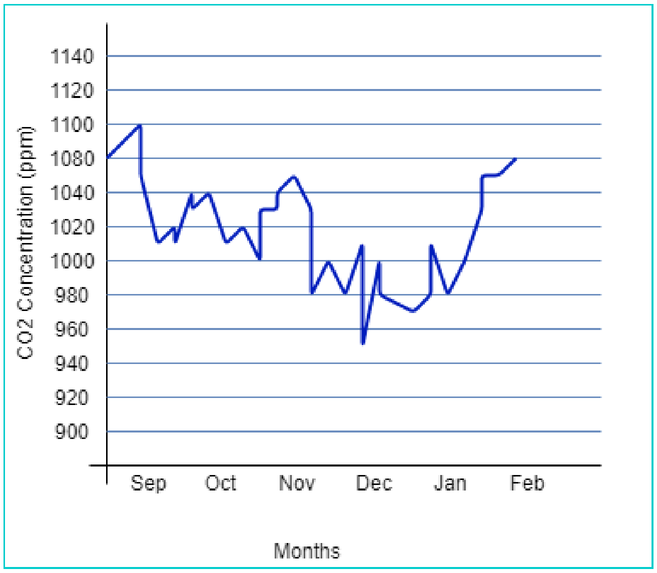

Fig. 7. Indoor CO2 concentration level for six months.

VII. Discussion

In the Discussion section of this paper, we critically examine the findings from our study on the implementation of a fuzzy PID controller for indoor climate control, with a particular focus on temperature regulation and CO2 level monitoring.

Temperature Control and CO2 Monitoring: Our research underscores the significance of precise temperature control and effective CO2 monitoring in indoor environments [48]. The implementation of a fuzzy PID controller demonstrated substantial efficacy in maintaining the desired temperature levels. This outcome is particularly noteworthy given the dynamic nature of indoor environments, where temperature can be influenced by various factors such as human occupancy, external weather conditions, and heating or cooling systems [49]. The fuzzy logic aspect of the controller, with its ability to handle imprecise inputs, proved crucial in adapting to these dynamic conditions.

Moreover, the CO2 level monitoring presents an additional layer of complexity. Unlike temperature and humidity, which are regulated within a defined range, CO2 levels require continuous monitoring to ensure they remain within safe limits. The study’s findings reveal that the integration of ventilation systems or natural air flow significantly impacts the reduction of CO2 levels, emphasizing the importance of adequate ventilation in indoor spaces for air quality management [50].

Performance of the Fuzzy PID Controller: The fuzzy PID controller's performance, particularly in the context of its rapid response and stability, is a highlight of this study. The controller's swift adaptation to changes in temperature and its ability to stabilize the indoor climate without overshooting the desired parameters underscore its efficiency [51]. The automatic tuning of PID parameters (kp, ki, and kd) according to fuzzy logic control rules further enhances the system's responsiveness and accuracy. This adaptability is crucial in scenarios where indoor conditions fluctuate frequently.

Limitations and Future Work: Despite the positive outcomes, there are limitations to this study that open avenues for future research. The study primarily focuses on a controlled environment, and extending these findings to more varied and complex real-world scenarios would be beneficial [52]. Further research could explore the integration of additional environmental factors, such as humidity levels and air pollutants, into the control system for a more comprehensive approach to indoor climate control.

Additionally, the study’s reliance on specific models and simulation tools may limit its generalizability. Future research could look into the application of the fuzzy PID controller across different models and simulation environments to validate its effectiveness further.

Implications for Indoor Air Quality (IAQ) Management: The findings have significant implications for IAQ management. Maintaining optimal levels of temperature and CO2 is not only essential for comfort but also for health. Elevated CO2 levels can lead to decreased cognitive function and increased health risks. Therefore, the ability of the fuzzy PID controller to effectively manage these parameters is crucial [53]. The insights gained from this study could inform the design and implementation of HVAC systems in various settings, from residential buildings to office spaces and public facilities.

Environmental and Energy Considerations: Environmental sustainability and energy efficiency are other critical aspects highlighted by this research. The intelligent control of HVAC systems, as demonstrated by the fuzzy PID controller, can contribute to energy conservation by optimizing the operation of heating and cooling systems. This optimization not only reduces energy consumption but also minimizes the environmental footprint of buildings.

The study presents a significant contribution to the field of HVAC system control, particularly in the areas of temperature regulation and CO2 monitoring. The implementation of a fuzzy PID controller demonstrates a promising approach to managing indoor climate conditions, balancing comfort, health, and energy efficiency. Future research expanding on these findings and addressing the identified limitations could pave the way for more sophisticated and environmentally sustainable indoor climate control solutions.

VIII. Conclusion

In conclusion, this research paper has made a significant contribution to the field of indoor climate control by exploring the efficacy of a fuzzy Proportional-Integral-Derivative (PID) controller in regulating temperature and monitoring carbon dioxide (CO2) levels in indoor environments. The findings of this study underscore the importance of precise environmental control in indoor settings, not only for occupant comfort but also for health and energy efficiency. The implementation of the fuzzy PID controller has demonstrated a commendable level of adaptability and accuracy in maintaining desired temperature levels, even in the face of varying indoor conditions and external influences. The integration of fuzzy logic with traditional PID control has enhanced the system's ability to handle ambiguous and fluctuating data, a common characteristic in real-world environments. Furthermore, the focus on CO2 level monitoring, a critical component of indoor air quality, highlights the necessity of continuous surveillance of environmental parameters beyond temperature and humidity.

A key takeaway from this research is the controller's capability to rapidly respond to changes in the indoor environment and stabilize the conditions without overshooting the set parameters. This responsiveness is crucial in ensuring a consistent and comfortable indoor climate. Additionally, the study's insights into the automatic tuning of PID parameters based on fuzzy logic control rules contribute to the broader understanding of intelligent control systems in HVAC applications. Despite its successes, the study acknowledges the need for further research in more diverse and complex settings to validate the generalizability of the findings. Future investigations could also delve into the integration of other environmental factors and explore the potential for advanced predictive control mechanisms.

In essence, this research provides a valuable framework for the development of sophisticated and efficient climate control systems, offering significant benefits in terms of occupant well-being, environmental sustainability, and energy conservation. The implementation of such intelligent control systems is poised to play a pivotal role in the evolution of smart building technologies and the advancement of indoor environmental quality.

***Abstract*—Remote sensing technologies, which are essential for everything from environmental monitoring to disaster relief, enable large-scale multispectral data collection. In the field of hyper-spectral imaging, where high-dimensional data is required for precise analysis, effective compression techniques are critical for transmission and storage. In the field of hyper-spectral imaging, the development of efficient compression techniques is critical because datasets containing high-dimensional information must be transmitted and stored efficiently without sacrificing analytical precision. The paper presents advanced compression techniques that combine deep Recurrent Neural Networks (RNNs) with multispectral transforms to achieve lossless compression in hyper-spectral imaging. The Discrete Wavelet Transform (DWT) is used to efficiently capture spectral and spatial information by utilizing the properties of multispectral transforms. Simultaneously, deep RNNs are used to model the hyper-spectral data with complex dependencies, allowing for sequential compression. The overall compression efficiency that is increased by the integration of spatial and spectral information allows for reduced storage requirements and improved transmission efficiency. Python software is used to implement the proposed model. When compared to Liner Spectral Mixture Analysis (LSMA) based compression, Spatial Orientation Tree Wavelet (STW)-Wavelet Difference Reduction (WDR), and DPCM, the proposed DWT-RNN-LSTM method has a better PSNR value of 45 dB and a lower MSE of 7.50%. Adaptive compression methods are presented in order to dynamically adapt to various data properties and ensure application in various hyperspectral scenes. Studies on hyper-spectral images of various sizes and resolutions demonstrate the approach's scalability and generalization, as well as the utility and adaptability of the proposed compression framework in a variety of remote sensing scenarios.**

Keywords*—Multi-Spectral transform; lossless compression; hyper-spectral data; deep recurrent neural network; compression algorithms

I. Introduction

Spectral imaging uses multiple bands across the electromagnetic spectrum, obtaining data simultaneously from imaging and spectroscopy. Multispectral remote sensors capture data from three to fifteen broad wavelengths, while hyper spectral sensors capture multiple bands. In contrast, several spectral bands spanning a wide wavelength range of 400–2500 nm are concurrently captured by hyper spectral (HS) remote sensors [1]. Spectrophotometry is the foundation of the hyperspectral imaging method. For every spatial area, numerous wavelengths and bands of data from images are collected. With the use of this data, a hyperspectral cube is produced, with the third dimension representing spectral content and the other two representing the location's spatial extent. Materials with varied qualities can be distinguished from one another thanks to the spectral signature, which is the result of particle scattering and molecule absorption [2]. Among the uses for hyperspectral remote sensing include criminal investigation, forecasting weather, agriculture, the food sector, and the medical field [3]. But this richness of information comes at a high memory cost because hyperspectral imagery generates a large amount of data that needs to be stored. These images' extreme richness stems from their high spectral dimensionality, which includes a wide range of spectral channels that capture subtle details about the scene or object under study. Since each pixel contains 16- or 12-bit data, a single HIS dataset might be hundreds of gigabytes (MBs) in size. The range of pixel values can range from a hundreds to millions, and the range of band numbers can be as high as 22 [4]. Compared to RGB and multispectral images, hyperspectral imaging (HSI) has a higher number of bands and a finer spectral resolution [5]. Hyperspectral images can contain dozens or even hundreds of spectral bands, whereas multispectral images usually only have a few. Over the past few decades, hyperspectral imaging has extended beyond traditional ground-based computer vision applications and shown great potential in a variety of fields, including recognizing faces, chemical engineering, farming, biology, and archaeological research. Its uses include material identification, record or ink aging, pen authentication, visual similarity ink differentiation, and documentation preservation.

With its ability to capture and analyze a wide range of contiguous spectral bands across the electromagnetic spectrum, this advanced imaging technology has become indispensable in a variety of fields, including remote sensing, agriculture, healthcare, and environmental monitoring. Hyperspectral imaging in environmental science allows for the accurate identification and tracking of ecological variables, which helps with well-informed conservation decision-making. It helps with disease detection, crop health assessment, and efficient resource allocation in agriculture. Hyperspectral imaging aids in diagnosis in the medical field by providing in-depth understanding of tissues and biological processes. Additionally, its uses in remote sensing enable businesses to obtain comprehensive data about the surface of the Earth, improving resource management and disaster response. Hyperspectral imaging's versatility and depth of data continue to spur innovation, making it a vital tool for a wide range of academic and professional projects.

One of the main concerns of compression algorithms that aim to reduce data redundancy is the difficulty of analysing large hyperspectral images (HSI) while preserving important information. Data redundancy and compression ratios are crucial in the field of multispectral images, such as Hyperspectral Imaging (HSI). Because redundant information gives compression algorithms plenty of opportunities to take advantage of similarities and patterns, high data redundancy in these images frequently results in elevated compression ratios. Multispectral images exhibit redundancy in four different flavours, each of which has a unique impact on the compression process. Similarities between spectral bands, where adjacent bands may convey similar information, give rise to spectral redundancy. Since neighbouring pixels in multispectral imagery frequently show similarities, spatial redundancy results from redundant information within the same spectral band of images. When thinking about sequential images over time, temporal redundancy is introduced, capturing redundant information across different moments. Lastly, inter-band redundancy adds to the overall redundancy landscape by involving correlations between various spectral bands. It is essential to comprehend and control these different types of redundancy when optimizing compression techniques for multispectral imagery. First, statistical redundancy is analysed through symbol probability, which is commonly done using entropy coding. Second, if pixel information can be partly acquired from nearby pixels and is reduced by transformations, spatial redundancy depends on intraband correlation. Thirdly, spatial decorrelation eliminates spectral redundancy, also known as interband correlation, which results from strong correlations between adjacent bands in hyperspectral images [6].

Finally, visual redundancy uses data quantization for compression based on visual redundancy, which is influenced by the insensitivity of the human eye to high frequencies. Compression methods are divided into two categories: two-dimensional and three-dimensional. They utilize correlations between or within bands [5]. Redundancy in multispectral images can occur in four ways: spectral redundancy, spatial redundancy, temporal redundancy, and inter-band redundancy. These factors complicate compression dynamics and require efficient management to develop compression strategies tailored to the unique properties of multispectral imagery. In order to achieve lossless compression, this research study investigates an advanced method of hyperspectral image compression that integrates deep recurrent neural networks (RNNs) with multispectral transforms. The purpose of this integration is to take advantage of the complex temporal dependencies and spatial-spectral correlations found in hyperspectral images in order to improve compression performance while maintaining crucial data for further analysis. DWT and PCA are two multispectral transforms that are initially utilized to take advantage of the spatial-spectral redundancies that are naturally present in hyperspectral data. In order to prepare the way for later compression stages, these transforms seek to decorrelate spectral information. To capture complex spatial correlations across the different spectral bands, deep recurrent neural networks which are well-known for their capacity to represent long-range dependencies are introduced as a building block. A synergistic approach to addressing the particular challenges posed by hyperspectral image compression is ensured by the seamless integration of deep RNNs and multispectral transforms. The aim of this work is to create an entire framework that best utilizes the advantages of deep RNNs and multispectral transforms while also achieving lossless compression and faithfully reconstructing the original hyperspectral image. The technique aims to achieve higher ratios without compromising the integrity of important spectral information by adaptively choosing and combining parameters according to the unique features of the hyperspectral data. This research presents a novel method for hyperspectral image compression, adding to the ever-changing field of remote sensing. Enhancing the efficacy and precision in remote sensing applications is possible through the integration of deep recurrent neural networks and multispectral transforms, which presents a promising solution to the problems posed by managing large volumes of hyperspectral data.

This study’s key contributions are as follows:

- Development of an advanced compression method for hyperspectral images that uses temporal dependencies and spatial-spectral correlations to seamlessly combine deep recurrent neural networks with multispectral transforms.
- Utilizing Discrete Wavelet Transform (DWT), to optimize the data for further compression stages in order to decorrelate spectral information.
- Enhancing the compression performance by capturing and taking advantage of intricate spatial correlations across the different spectral bands using deep RNN, more especially Long Short-Term Memory (LSTM) networks.
- Integrated spectral and spatial information using deep RNNs and multispectral transforms. This integration seeks to improve compression efficiency by utilizing

the correlation between adjacent pixels and spectral bands.

The structure is organized like the following. Section II explores works that are similar to the current study by exploring into the body of previous literature in the topic. After that, the problem statement is outlined in Section III, along with the particular difficulties that the study attempted to solve. The methodology of the suggested model, including its numerous components and methods, is expounded upon in Section IV. Next, a thorough discussion is started in Section V, which provides a concise summary of the results. Section VI provides a conclusion of the research outcome and considerations for further research.

II. Related Works

Li et al. [7] suggested a proposal for remote sensing multispectral image compression using convolution neural networks and multispectral transforms. The benefits of TD, such as Nonnegative Tucker Decomposition, can be used to compress multispectral images. CNN with NTD is the foundation of a low-complexity compression method for multispectral images that was developed. A novel spectrum transform was employed, leveraging CNNs to convert the three-dimensional spectral tensor from a large to small-scale version. The initial and rebuilt three-dimension spectral tensor in self-learning CNNs were minimized in order to produce the optimized spectral tensor for small scale. To increase computation efficiency, the NTD resources only allot the small-scale three-dimension tensor. The result shows that the computation efficiency improved by 49.66% by sacrificing only 0.3369 dB compared to NDT. The drawback is the essential to implement a complex learning network to reduce computational costs.

Cabronero et al. [8] Proposed High-Efficiency Lossless Compression of Spectral Decorrelation. To obtain as many HSI scenes on the ground as possible, data reduction is a crucial tool. Simultaneously, space borne devices' energy and hardware limitations place restrictions on the complexity of workable compression algorithms. In this study, only lossless compression is taken into consideration to prevent any distortion in the analysis of the HSI data. The goal of this work is to determine the optimal trade-off between complexity and compression for high-spatiality HSI compression. The goal of this work is to determine the best possible trade-off between complexity and compression for high-spatiality images (HSI) compression. Results regarding the execution time and compression performance are obtained for a collection of 47 HSI scenes generated by 14 distinct sensors during actual remote sensing missions. The results obtained indicate that the FAPEC algorithm provides the best trade-off, assuming that there is only a finite amount of energy available.

Dua et al. [9] suggested a lossless prediction-based multi-temporal image compression method in this research. It greatly reduces the size of the time-lapse hyperspectral image by eliminating temporal correlations. It uses a linear combination of pixels from previously estimated spectral and temporal bands to predict the target image's pixel value. The RLS filter is used to update the weight matrix that is used in the prediction. The best number of bands to choose for prediction, the relative strength of each correlation, and the bit-rate efficiency of the method are all shown by the experimental results. According to the findings, adding temporal correlations lowers the bit-rate by 24.07%, and the model optimizes the bits per pixel by 18.15% when compared to the most advanced technique. The disadvantage is that designing a universally applicable solution becomes difficult when automating the entire process and dealing with a variety of datasets and scenarios. Furthermore, the process of creating an automatic model to determine the number of temporal prediction bands might encounter challenges in precisely encapsulating the subtleties of different datasets, which could result in less-than-ideal performance in specific scenarios.

Deng at al. [10] proposed a model, utilizing Generative Neural Networks for Learning-Based Hyperspectral Image Compression. The research presented an alternative method of HSI compression using a GNN, which uses a random latent code to learn the distribution of probability of the actual data. To do this, it's necessary to must define a family of densities and identify the one that minimizes the difference between the actual data distribution and this family. The HSI is then represented by the well-trained neural network, and the complexity of the GNN controls the compression ratio. Additionally, the latent code can be made secret by encrypting it with a random distribution digit embedded in it. To show the GNN potential in resolving compression issues of images in the field of HSI, experimental examples are provided. This work presents a novel neural network-based compression technique and opens up a wide range of new research avenues. Other structures can be added to increase the compression ratio is the major drawback. Additionally, since the neural network can be thought of as a representation of the HSI, the GNN can be used directly for many tasks, including classification, by manipulating its layer to match the classification label.

Makarichev et al. [11] suggested a Quality Controlled Lossy Compression of Three-Channel Remote Sensing data via Discrete Atomic Transform, three-channel RS images are utilized. It is shown how varying and controlling the maximal absolute deviation can affect the quality of images compressed by DAT. Additionally, there is a strict relationship between this parameter and more conventional metrics like PSNR and RMSE, which can be adjusted. Additionally, it is demonstrated that the depths of the various DAT variants vary. A variety of perspectives are used to compare their performances, and transform depth suggestions are provided. The disadvantage is that DAT-based compression cannot be extended to RS data or to other practical tasks like classification of crops, forest cut monitoring, etc.

Grassa et al. [12] proposed a Compression of Hyperspectral Data Using a Fully Convolutional Autoencoder. A new deep convolutional auto encoder architecture-based Spectral Signals Compressor Network. Comprehensive tests were carried out on a variety of multi/hyperspectral and RGB datasets, demonstrating significant gains over baselines and outperforming conventional JPEG family algorithms. The outcomes demonstrate the effectiveness of SSCNet in obtaining better compression ratios and reconstructing spectral signals, especially showing resilience when dealing with data types larger than 8 bits. Moreover, thorough assessment employing PSNR, SSIM, and MS-SSIM standards consistently demonstrates SSCNet's superiority over current techniques, confirming its mastery of spectral signal compression. The efficacy and accessibility of the framework across RGB, multi spectrum, and hyperspectral sources were proven through extensive experiments on multiple benchmark datasets, which also reported a high compression ratio achieved and an excellent reconstruction.

Changcheng et al. [13] suggested a matrix with an invertible method to eliminate spectral redundancy and improve bit allocation inside the structure. To reduce redundancy, the method combines the DWT's lifting scheme with other strategies like SPIHT coding. The experimental results highlight how well the suggested algorithm performs in lossless compression when compared to well-known techniques. When compared to the previously mentioned algorithms, the results show a significant average compression ratio improvement of roughly 73.6 % respectively, using the JPL Canal test image as a benchmark dataset.

Leo et al. [14] proposed Hyperspectral image compression without losses with recurrent neural networks. The spectral and spatial resolution of hyperspectral images are constantly rising due to the rapid growth of hyperspectral sensor technology, which in turn is causing the scale of hyperspectral data to grow exponentially. Hyperspectral compression with no loss technology is currently at a standstill. At the same time, the emergence of machine learning has given us fresh concepts. Consequently, the application of deep learning to the lossless compression of hyperspectral images is examined in this paper. Given that the DPCM method is inadequate for forecasting spectral band information, a deep (RNN) is used in the proposed C-DPCM-RNN method to enhance the conventional DPCM method and boost the model's capacity for generalization and prediction accuracy. The ultimate experimental outcome demonstrates that C-DPCM-RNN performs better.

Among the difficulties in compressing multispectral images from remote sensing are the need for novel ways to deal with computational complexity, trade-offs between complexity and compression, the need for universality in compression solutions, and the limitations of existing compression techniques in handling a variety of datasets and real-world applications. Multi-temporal image compression challenges include the need to address the limitations of discrete atomic transform (DAT) in order to extend compression methods to other remote sensing data types and useful applications, as well as the development of globally applicable solutions for a variety of datasets and scenarios. New approaches are needed to address these issues and improve the effectiveness and versatility of compression methods in order to improve the state of multispectral image compression.

III. PROBLEM STATEMENT

Because of the growing amount of hyperspectral imaging data in remote sensing, the previously mentioned literature identifies common issues with storage, transmission, and computational handling. Traditional compression techniques do not handle the complex temporal dependencies and spatial-spectral correlations found in hyperspectral images. To achieve lossless compression, an advanced compression strategy combining deep recurrent neural networks and multispectral transforms must be established. Some of the challenges are the complex spatial-spectral nature of hyperspectral data, the need for computational efficiency, particularly in real-time applications, the need to record and maintain temporal dependencies, adaptability across diverse datasets, and the need for lossless compression to retain critical information [15]. Resolving these issues is critical for improving remote sensing capabilities and ensuring the preservation of hyperspectral data for applications such as agriculture, disaster relief, and environmental monitoring, among others. The proposed method aims to provide a comprehensive response by optimizing hyperspectral data utilization in ways that are both useful and resource efficient.

IV. PROPOSED METHODOLOGY FOR EFFECTIVE LOSSLESS HYPER-SPECTRAL IMAGE COMPRESSION

The proposed methodology of this research involves data collection procedure entails obtaining hyper-spectral images, and to improve contrast throughout the spectral bands, histogram equalization is used for image pre-processing. Consistent contrast enhancement is ensured by the adaptability of histogram equalization to multispectral data. This allows for easier compression in the future and balanced information representation. The impact of compression on performance is assessed using pertinent metrics, and parameters are adjusted based on the requirements of the compression model and the characteristics of hyper-spectral data. The pre-processing step incorporates the histogram equalization seamlessly before multispectral transforms are applied and data is fed into a Deep Recurrent Neural Network (DRNN). The process is essential for preserving information fidelity and optimizes compression by emphasizing subtle features. To efficiently capture spatial-frequency information, the compression pipeline incorporates the DWT. The core of DWT is multi-resolution analysis and sub-band coding, which improve compression in conjunction with DRNN and multispectral transforms. The recurrent nature of the DRNN architecture, which propagates historical information through hidden state vectors, is highlighted in detail. Long-short term memory cells are used in the architecture to provide enhanced memory capabilities and selective information retention through gates, helping to overcome issues like gradient vanishing or exploding Compared to conventional compression techniques, this all-encompassing strategy provides a more holistic representation of the hyper-spectral data and may result in improved compression performance without compromising analytical precision. Furthermore, by employing sophisticated neural network architectures, the model can be made adaptive and learn from the data, which lets it adapt dynamically to various hyper-spectral scene types and maximize compression effectiveness. The block diagram of the proposed methodology is given in the below Fig. 1.

Histogram Equalization for Data Pre-Processing
Integrating DWT Module to Represent Spatial-Frequency Information
RNN-LSTM Module (Compression & Analysis)
Performance Evaluation

Fig. 1. Overall block diagram of the proposed methodology.

A. *Data Collection*

Indian Pines hyperspectral datasets in [16] were utilized in order to validate the efficiency of the proposed method. The Indian Pines dataset is used for hyperspectral image compression. The input data is made up of 145x145 pixel hyperspectral bands covering a single landscape in Indiana, US (Indian Pines data set). The dataset of Indian Pines is gathered by the AVIRIS sensor. The dataset comprises resolution of 20 m and 220 spectral bands spanning from 0.4 to 2.5 µm.

B. *Image Pre-processing using Histogram Equalization*

By increasing the contrast of hyper-spectral images, histogram equalization helps to highlight subtle features and may even improve the performance of subsequent compression methods. Consistent contrast enhancement across all spectral bands is ensured by its adaptability to multispectral data, which helps with compression and promotes a more balanced information representation [17]. Histogram equalization supports lossless compression by avoiding information loss brought on by certain characteristics in the original images being difficult to see. Histogram equalization's effect on compression performance should be assessed using pertinent metrics, and parameters should be fine-tuned in accordance with the demands of the compression model and the unique properties of hyper-spectral data. A comprehensive strategy for improving the general quality and efficacy of compression in hyper-spectral imaging is ensured by fully integrating into the pre-processing procedure prior to the application of multispectral transforms and data feeding into the deep recurrent neural network. Histogram Equalization allows for more contrast to be obtained from a smaller localized intensity differential. It seeks to improve the picture's visual attractiveness and ease of analysis. The intensity spreading values of a picture can be seen as arbitrary numbers, ranging from 0 to S-1. The term "random calculation" can also refer to the accompanying cumulative distribution function. The likelihood that an arbitrary value will be assigned a value that is less than or equal to a given value is defined by this function.

Denote the input image f as an array of numerical pixels with intensities values within the range of 0 to S − 1, where S is the intensity probability value. Additionally, q denotes regularized histogram of the primary image (f). Eq. (1) represents the general formula for q and g.

$$qn = \frac{number\ of\ pixels\ with\ intensity\ n}{total\ number\ of\ pixels} \quad \text{n=0, 1 …, L-l} \qquad (1)$$

Eq. (2) represents the histogram equalization of the image.

$$h_{i,j} = flor(S-1)\sum_{n=0}^{f_{i,j}} qn \qquad (2)$$

The flor (.) changed to the closest down integer as a result. This is equivalent to applying the following Eqn. (3) to the values of the densities, k, of 'f ':

$$R(k) = flor(S-1)\sum_{n=0}^{k} qn \qquad (3)$$

This conversion was inspired by considering the densities for f and h as continuous arbitrary values T, H over a time spanning from 0 to L − 1, where Z is a variable. Eq. (4) represents intensity formula is given below.

$$H = R(T) = (S-1)\int_0^x q(x)dx \qquad (4)$$

where, q(x) is the probability intensity formula for g. R is the product of T's collective distribution values and product of (S-1). It will be easier to suppose that the variable U is differentiable and invertible. While the function U(X) denotes T, which is normally distributed.

C. *Integrating Discrete Wavelet Transform*

In 1976, Crochiere introduced sub-band coding for the first time, which laid the groundwork for the discrete wavelet transform [18]. Pyramidal coding, also referred to as multi-resolution analysis, is a method that Burt defined in 1983 and is strikingly similar to sub-band coding [19]. Later, Vetterli and Le Gall eliminated the redundant elements from the pyramidal coding scheme and made some adjustments to the sub-band coding scheme. The system is able to effectively capture and represent the spatial-frequency information present in remote sensing data by adding DWT to the compression pipeline. The combination of DRNN and multispectral transforms improves compression even more, preserving complex features and patterns in hyper-spectral images. This integration opens the door for more precise and efficient downstream analysis in addition to optimizing the transmission and storage of remote sensing data. The combination of these cutting-edge methods is leading the charge in pushing the limits of compression techniques in the context of hyper-spectral imaging, which presents a promising path for improved data management and analysis in remote sensing applications.

The primary signal in DWT is passed through a half-band digital low-pass filter with an impulse response of h[n]. Eq. (5) illustrates the convolution of the signal.

$$y[n] * h[n] = \sum_{k=-\infty}^{\infty} x[k].h[n-k] \qquad (5)$$

By transferring the signal (y[n]) through a half-band low-pass filter, all frequencies higher than half of the primary signal's peak frequency are eliminated. The Nyquist's rule states that half of the samples can be removed. As indicated by Eq. (6), this process involves down sampling (or subsampling) the low-pass filter's output by two.

$$z[n] = \sum_{k=-\infty}^{\infty} h[k].\, y[2n-k] \qquad (6)$$

This process, which makes up one level of decomposition in DWT, can be mathematically expressed using Eq. (7) and Eq. (8) in which the output of the high and low-pass filters following down sampling is denoted by $z_{high}[k]$ and $z_{low}[k]$.

$$z_{high}[k] = \sum_n y[n].\, g[2k-n] \qquad (7)$$

$$z_{low}[k] = \sum_n y[n].\, h[2k-n] \qquad (8)$$

Sub-band coding is the name for this type of decomposition, which doubles frequency resolution and halves time resolution. It can be repeated for additional decomposition by filtering the low-pass filter's output.

The output of DWT is [p3.q3.q2.q1], as shown in Fig. 2. The frequency specifications of the primary signal and its filters are linked to the decomposition levels for DWT. Ultimately, the original signal's DWT is acquired by concatenating all coefficients, commencing from the final decomposition level. Therefore, the DWT coefficients equal the coefficients of the original signal.

D. *Architecture of Deep Recurrent Neural Networks (RNNs) for Effective Lossless Compression*

Using a series of vectors, recurrent architecture can propagate past information to the current unit (i.e., represented by hidden state vectors) through RNN operations. Recurrent neural networks (RNNs) have demonstrated exceptional performance in time-sequence data processing, such as recognizing speech and processing natural languages [20]. The fact that a sample and its predecessors usually have a strong correlation is an important feature of a time sequence. The probability of a particular state in the hidden Markov model, a model that is frequently used in language processing, depends only on its prior state.

Let Y = $[y_1, y_2, \cdot\cdot\cdot, y_t]$ represent the sequence of data, with t representing the state label. The data at the first state is represented by Y_1, and the data at the t state is represented by Y_t. One way to formulate the Markov assumption in (9).

$$P(y_t\ |y_1, \cdot\cdot\cdot, y_{t-1}) \ = \ P(y_t\ |y_{t-1}) \qquad (9)$$

where, the conditional probability is expressed by P (·). RNN and HMM are comparable in that they both rely on an earlier state for computation of the current state. Unlike traditional ANNs, the RNN processes sequential data in a circular manner, meaning that each data instance in the sequence will receive the same processing, with each state's outcome depending on the state before it. The parameter sharing is also represented by this circular processing. One common technique to limit the number of parameters in a DL scheme is parameter sharing. Nevertheless, assuming sequential data Y = $[y_1, y_2, \cdot\cdot\cdot, y_t]$ the hidden state r_t can be expressed in (10).

$$D_t \ = \ f_d(X_{dy}y_t \ + X_{dd}D_{t-1} \ + \ b_t) \qquad (10)$$

where, X_{dy} represents the weight matrix from the source data to the hidden state andX_{dd}, the current state to the subsequent state. The bias variable is b_t. The nonlinear function of activation is represented by f_d (·), and the hidden state at time step t is indicated by D_t.Equation (11) and the output calculation at state t are very similar.

$$z_t \ = f_z(X_{dz}D_t \ + b_z) \qquad (11)$$

where, X_{dy}represents the weight matrix connecting the output and hidden state. $f_Z(\cdot)$ is the nonlinear activation function, and by is the bias.

Since the hidden state (D_t) is computed via forward propagation using the previous state as a basis, it can be thought of as the RNN model's memory. Sequential data from earlier states are also taken into account in the interim. Unlike a traditional neural network, some parameters in such forward propagation—such as the three distinct weight matricesX_{dd}, X_{dy},, and X_{dz}, —are shared throughout all steps. By reducing the number of trainable parameters, the parameter-sharing scheme improves the efficiency of the entire computation. Fig. 3 depicts the architecture of deep RNN-LSTM is given.

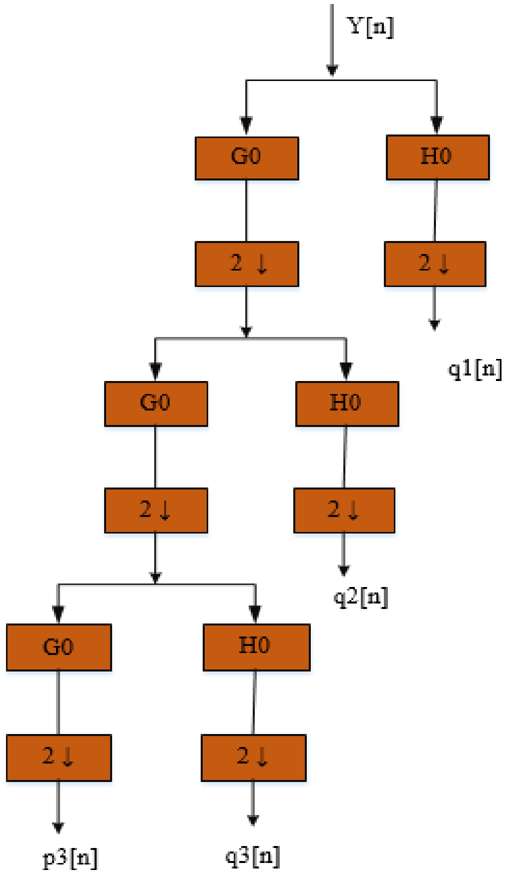

Fig. 2. Architecture of discrete wavelet transforms.

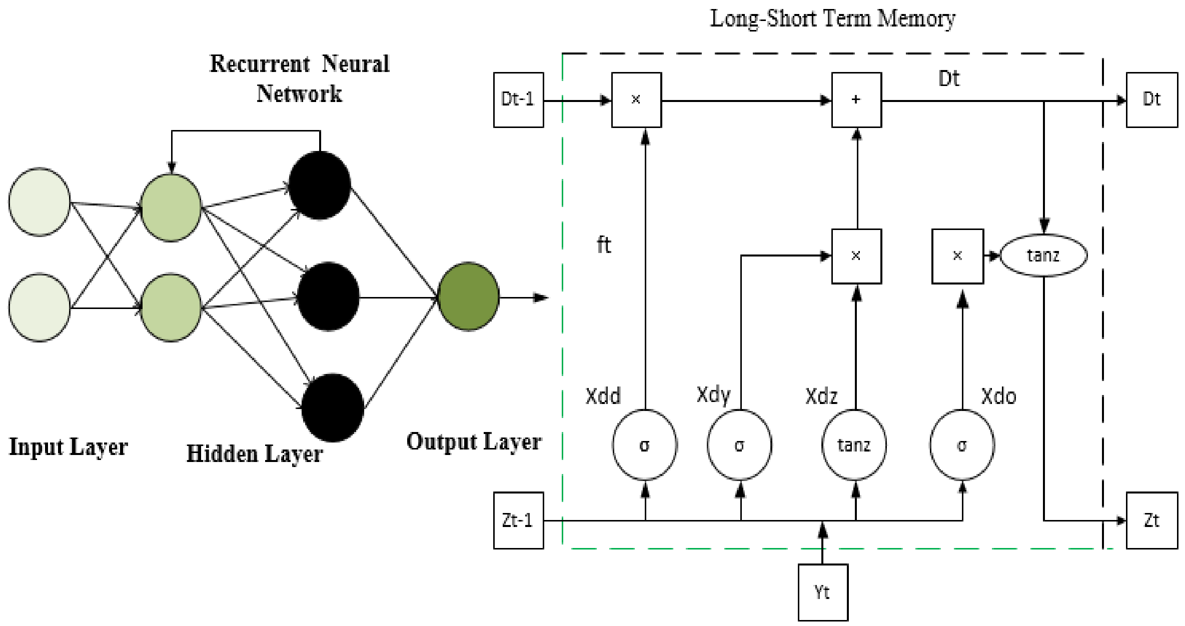

Fig. 3. Deep RNN–LSTM architecture.

LSTM was created using advanced recurrent neuron. Every recurrent neuron in an LSTM can be thought of as a single cell state [21]. LSTM uses the previous state as the input to the current state, just like the traditional RNN. To control the current neuron, the LSTM uses three gates: the forget gate, update gate, and output gate.

An LSTM network has the ability to recall and make connections between data gathered in the past and current. Three gates are coupled with LSTM: an input gate, a forget gate, and an output gate [22]. The input is denoted by D_t and D_{t-1}, denotes new and last state respectively, and the current and prior outputs by z_t and z_{t-1}.

Fig. 4 depicts the proposed DWT-RNN-LSTM Network model's overall workflow. The DWT-RNN-LSTM Network that has been proposed can efficiently compress hyper-spectral images with greater efficiency, and provide a more trustworthy for the lossless compression of images.

The following forms illustrate the LSTM input gate idea.

$$i_t = \sigma(\mathrm{X}_i \cdot [z_{t-1}, y_t] + b_i) \quad (12)$$

$$\widetilde{D}_t = \mathrm{tanz}(X_i \cdot [z_{t-1}, \mathrm{y}_t] + \mathrm{b}_i) \quad (13)$$

$$\mathrm{D}_{\,t} = f_t \mathrm{D}_{\,t-1} + i_t \widetilde{D}_t \quad (14)$$

where, Eq. (12) determines which piece of data should be added by passing z_{t-1} and y_t through a sigmoid layer. When z_{t-1} and y_t have travelled through the tanz layer, Eq. (13) is then used to get new information. In Eq. (14), the long-term storage data D_{t-1} into D_t and the present moment information,$\widetilde{D}_t$, are merged. X_i denotes a sigmoid output, while $\widetilde{D}_t$ stands for tanz output. Here, b_t stands for the LSTM input gate bias while X_i stands for weight matrices. The LSTM's forget gate then enables the dot product and sigmoid layer to selectively pass information. With a certain probability, the choice of whether to delete relevant data from an earlier cell is carried out. Eq. (15) is used to determine whether or not to retain relevant information from a preceding cell with a particular chance. X_f stands for weight matrix, b_f for offset, and σ for sigmoid function.

$$f_t = \sigma\,(X_f \cdot [z_{t-1}, y_t] + \mathrm{b}_f) \quad (15)$$

The output gate of the LSTM ascertains the necessary states for the subsequent Eq. (16) and Eq. (17) states provided by the z_{t-1} and y_t inputs. After obtaining the final output, the state decision vectors that send fresh data,D_t, via the tanz layer are multiply by it.

$$P_t = \sigma(X_o \cdot [Z_{t-1}, y_t] + b_o) \quad (16)$$

$$z_t = P_t \,\mathrm{tanz}(\mathrm{D}_{\,t}) \quad (17)$$

where, the weighted matrices X_o and the bias b_o, respectively.

V. Results

The outcomes of the proposed methodology demonstrates how well it works to achieve optimal compression and consistent contrast enhancement for better data analysis in remote sensing applications. In order to ensure balanced information representation, histogram equalization is used as a pre-processing step, demonstrating its adaptability to multispectral data. By combining DWT with LSTM cells and deep recurrent neural network (DRNN), problems such as gradient vanishing or exploding are avoided and information fidelity is preserved while historical data is retained selectively. The methodology's success in capturing subtle features and managing hyper-spectral data efficiently is confirmed by the assessment of the impact of compression using pertinent metrics. The talk focuses on the potential for further developments, such as the investigation of optimization methods, incorporation of more machine learning algorithms, creation of models for adaptive compression, and expansion of applications to different remote sensing fields. On the Anaconda platform, the programming language of choice was Python. The following metric was used to assess the model's efficiency. The influence of compression on performance is carefully examined using appropriate metrics, and model parameters are changed depending on the compression model's unique requirements and the intrinsic properties of hyper-spectral data. This complete approach assures that the suggested technology not only accomplishes effective compression but also maintains information integrity, which is critical for remote sensing applications. Finally, the model's benefit is its ability to smoothly incorporate histogram equalization, multispectral transforms, DRNNs, and DWT, resulting in a comprehensive solution for advanced lossless compression in hyper-spectral image.

A. *Performance Evaluation*

Metrics for performance evaluation, like PSNR and MSE are essential for determining the quality of compressed or reconstructed images. Even though these metrics provide quantitative insights, subjective assessments are frequently added to obtain a complete picture quality assessment. A comparison is made between the suggested model and the performance of LSMA based compression, STW-WDR, and DPCM.

1) PSNR: PSNR for simple terms is a metric frequently used to assess the effectiveness with which an image has been compressed. When comparing the quality of a reconstructed or compressed hyperspectral image to the original, PSNR can be used to assess hyperspectral images, which are images taken in multiple bands across the electromagnetic spectrum.

The following Eq. (18) is used to determine the PSNR:

$$PSNR = 10.log_{10}\left(\frac{MAX^2}{MSE}\right) \tag{18}$$

- The maximum pixel value that an image can have been referred to as MAX (255 for 8-bit images, for example).

- The average of the squared pixel-wise differences between the original and compressed images is termed as the Mean Squared Error, or MSE.

Since a higher PSNR value suggests less distortion or error in the compressed image, it typically denotes higher image quality. A higher PSNR is preferred in lossless compression since the objective is to reach high compression ratios without sacrificing the quality of the original image.

2) Mean Square Error: MSE is a statistic frequently used to express the average squared differences between matching pixels in two different images. MSE is frequently used in image processing and compression to assess how well a reconstructed or compressed image compares to the original.

The following Eq. (19) is the formula for mean squared error:

$$MSE = \frac{1}{n \times m} \sum_{p=1}^{n} \sum_{q=1}^{m} (I(p,q) - L(p,q))^2 \qquad (19)$$

- The intensity of the corresponding pixel in the original image is represented as I (p, q).
- In a compressed or reconstructed image, L (p, q) denotes the intensity of the corresponding pixel.

The squared difference between each pair of corresponding pixels is used to calculate the mean square error (MSE). This squared difference is then added up and divided by the total number of pixels (n × m). Better image fidelity is implied by a lower MSE value, which shows less variation between the original and reconstructed images. MSE, however, may not always correspond with human visual perception and does not directly account for perceptual differences. Because of this, when assessing image quality, it is frequently used in conjunction with other metrics and subjective evaluations.

The performance metrics of several image compression techniques, such as LSMA-based compression, STW-WDR, DPCM, and the suggested DWT-RNN, are compared in the Table I. The suggested DWT-RNN approach outperforms all other techniques in terms of PSNR, attaining a noticeably higher value of 45 dB. Additionally, it exhibits better Mean Squared Error (MSE) performance than the other methods, with the lowest value of 7.50%, indicating improved compression efficiency and image quality. These other methods include LSMA based compression, STW-WDR, and DPCM.

TABLE I. THE SUGGESTED METHOD'S PERFORMANCE METRICS ARE COMPARED TO THOSE OF EXISTING METHODS

Methods	PSNR (dB)	MSE (%)
LSMA based Compression [23]	33	20.57
STW-WDR [24]	35	18.02
DPCM [25]	30	17.09
Proposed DWT-RNN	45	7.50

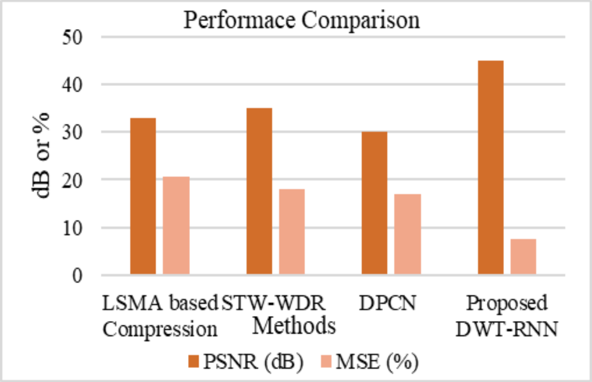

Fig. 5. Performance comparison with the existing methods.

The loss values against number of epochs are shown in Fig. 6. It shows the overall loss from the proposed DWT-RNN-LSTM Method's Loss is illustrated graphically.

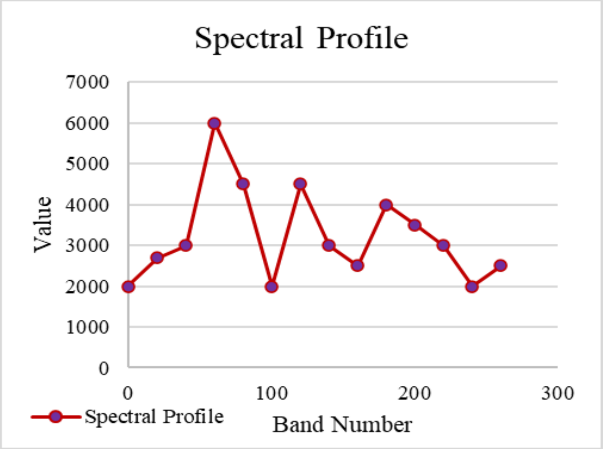

Fig. 7. Proposed DWT-RNN-LSTM method's spectral profile is illustrated graphically.

Fig. 7 depicts the graphical illustration of Spectral profile of the proposed model. The spectral profile is a critical component in advanced remote sensing image compression method because it allows for lossless compression in hyper-spectral imaging. The distribution of electromagnetic energy across different wavelengths, which captures the distinct signature of materials present in a scene, is referred to as the spectral profile. Optimizing compression efficiency requires combining deep recurrent neural networks (RNNs) with multispectral transforms.

TABLE II. PSNR OF DWT-RNN-LSTM METHOD IN EACH COMPRESSED RATION

Compression Ratio	PSNR (dB)
1	45
2	44
3	42
4	40
5	38
6	33
7	30

Table II represents the PSNR of DWT-RNN-LSTM method in each compressed RATION and it exhibits an effective lossless compression output.

Fig. 8 depicts the graphical illustration of PSNR of the proposed model. Higher PSNR values indicate better original information preservation. It provides a numerical measure of image fidelity by quantifying the ratio of the signal strength of maximum values to the noise introduced during compression.

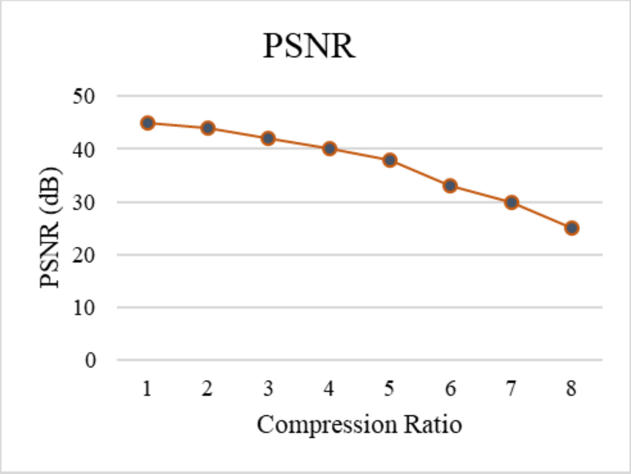

Fig. 8. Proposed DWT-RNN-LSTM method’s PSNR is illustrated graphically.

B. Discussion

The proposed approach to hyperspectral image compression shows notable improvements in attaining ideal compression and contrast enhancement for remote sensing applications by integrating DWT with LSTM cells and deep recurrent neural network. The approach's flexibility in handling multispectral data is demonstrated by the pre-processing step of histogram equalization, which guarantees balanced information representation. When DWT is combined with LSTM and DRNN, problems like gradient vanishing or exploding are successfully resolved, maintaining information fidelity and keeping some historical data. PSNR and MSE, are three performance evaluation metrics that show how much better the suggested DWT-RNN approach is than the state-of-the-art techniques like LSMA-based compression [23], STW-WDR [24], and DPCM [25]. In comparison to other methods, the higher PSNR value of 45 dB and lower MSE of 7.50% show better compression efficiency and superior image quality.

A graphic confirmation of the methodology's effectiveness can be seen. A performance comparison with current approaches is mentioned clearly, where the higher PSNR value of the suggested DWT-RNN is highlighted. The loss values are plotted against the number of epochs is shown graphically, which shows how stable and convergent the model was during training. The spectral profile of the suggested model highlights the significance of combining multispectral transforms and deep recurrent neural networks for the best compression in hyperspectral imaging. Lastly, Figure 8 shows the PSNR of the suggested model graphically, highlighting how well it can retain original data. Together with the quantitative metrics, these visual aids offer a thorough evaluation of the effectiveness of the suggested methodology for advanced hyperspectral image compression in remote sensing applications.

VI. CONCLUSION AND FUTURE SCOPE

In conclusion, this comprehensive and inventive hyper-spectral image compression methodology employs DRNN with long-short term memory cells, multispectral transforms, and histogram equalization for contrast enhancement. Problems like gradient vanishing and explosion are solved by incorporating the DWT, and spatial-frequency information capture is improved. The compression parameters are adjusted adaptively based on the needs of the model and the properties of the hyper-spectral data to ensure efficiency. Deep recurrent neural networks and multispectral transformations may limit real-time processing capabilities or necessitate high-performance computing infrastructure due to their probable requirement for large computational resources during both the training and compression phases. Future research directions include looking into more complex optimization strategies, incorporating more machine learning algorithms, developing adaptive compression models, investigating hardware acceleration, and expanding applications to different remote sensing domains, and designing intuitive user interfaces and visualization tools. This methodology establishes a solid foundation for future research into the compression of hyper-spectral images for various remote sensing applications.

***Abstract*—One of the most challenging tasks while processing natural language text is to authenticate the correctness of the provided information particularly for classification of fake news. Fake news is a growing source of apprehension in recent times for hate speech as well. For instance, the followers of various beliefs face constant discrimination and receive negative perspectives directed at them. Fake news is one of the most prominent reasons for various kinds of racism and stands at par with individual, interpersonal, and structural racism types observed worldwide yet it does not get much importance and remains to be neglected. In this paper, to mitigate racism, we address the fake news regarding beliefs related to Islam as a case study. Though fake news remained to be a concerning factor since the beginning of Islam, a significant increase has been noticed in it for the last three years. Additionally, the accessibility of social media platforms and the growth in their use have helped to propagate misinformation, hate speech, and unfavorable views about Islam. Based on these deductions, this study intends to categorize such anti-Islamic content and misinformation found in Twitter posts. Several preprocessing and data enhancement steps were employed on retrieved data. Word2vec and GloVe were implemented to derive deep features while TF-IDF and BOW were applied to derive textual features from the data respectively. Finally, the classification phase was performed using four Machine-based predictive analysis (ML) algorithms Random Forest (RF), Naïve Bayes (NB), Logistic Regression (LR), Support Vector Machine (SVM), and a custom deep CNN. The results when compared with certain performance evaluation measures show that on average, ML-models perform better than the CNN for the utilized dataset.**

Keywords*—Machine learning; deep learning; fake news detection; social media

I. Introduction

One of the most challenging tasks while processing natural language text is to authenticate the correctness of the provided information particularly for classification of fake news. Fake news is a growing source of apprehension in recent times for hate speech as well. For instance, the followers of various beliefs face constant discrimination and receive negative perspectives directed at them. Fake news is one of the most prominent kinds of racism and stands at par with individual, interpersonal, and structural racism types observed worldwide yet it does not get much importance and remains to be neglected. In this paper, we address the fake news regarding beliefs related to Islam as a case study. Fake news is concerned with the type of racism done against Islam or Muslims which can be in the form of speech, text, news, attitude, behavior, or emotions. Any negative mention of Islam, Muslims, their mosques, rituals, religious practices, and holy books indicates the origin of fake news and recently United Nations Organization (UNO) has adopted a resolution to observe March 15 as international day to combat fake news [1]. Although it is one of the most prevalent forms of racism currently being noticed, no action has been made to confront or eradicate it. Web and social media are the major sources of spreading fake news-related content worldwide. As per Belgium's statement on fake news, political discussions and actions that were sanctioned addressing Muslim women's headscarves, the production of acceptable meat, and other Islamic traditions increased in 2017 [2]. Anti-Muslim acts have also increased significantly in China. As per a poll conducted in China during the year 2018, the acts of intolerance have been noticed against Muslims in terms of job opportunities, indoctrination availability, medical facilitation. They also face biasness in their social and electronic media representations [3]. According to a report distributed by 2019 in Europe, incidents like the Christchurch terrorist attack, Philip Manshaus' attempted attack on the Baerum mosque, and some physical assaults that took place in the United Kingdom post Christchurch incident are all the result of religious discrimination, hate speech, and derogatory social posts against the followers of Islam [4]. Furthermore, hate crime, social harassment, abusive behavior, and other Anti-Muslim activities have amplified over time in France [5], America [6] because of Donald Trump's statement regarding Anti-Islamic culture, Canada [7], Wisconsin [8], India during COVID-19 [9], and Israel [10]. Fake news is a major issue that is on the rise but has not been recognized on higher levels thus making it a matter of concern to figure it out and analyze its progress over the physical and electronic channels [40, [41]. Apart from this, the followers of Islam vary across different countries in terms of number which also impacts the level of fake news activities occurring in a particular region and there is no specific way to analyze it generically.

Some of the aspects that contribute to propagating fake news include lack of Islamic knowledge, a superficial and abstract understanding of its enactments, a non-acceptance behavior, extremist nature, and irresponsibility concerning other beliefs. A study done in USA during 1993 indicates that most people had negative ideas about Islam despite having little to no understanding of the religion. The balance of the population had positive impressions of Islam and knew something about it. This is because there is a deluge of inaccurate, unfriendly, and arsonist-related news about Islam and its followers on electronic channels. When a novice attempts to learn or research something, they only ever receive these inaccurate feedbacks [11]. Even while most communal channels have developed hand-made strategies for the brisk rectification of extreme content, there is still a long way to go in terms of automating this process. It is necessary to move away from the labored process of going through each article, tweet, or any electronic post, in favor of an automated system that can input a corpus of textual data, identify the content, and categorize it. The developments in the field of processing semantics language, machine-driven understanding of stuff, and layered models have assisted in the development of such systems that can orderly perform such tasks with utmost accuracy [12]. These tools are being widely utilized in the latest social media platforms and have provided great results till now.

In the proposed work, we contribute to propose a fake news classifier (FNC) model as follows: fake news data instances retrieved from Twitter is analyzed and classified using a variety of ML frameworks with the addition of a DL schema; the labeled tweet data is dispensed as an input to the constituted model in the form of single and multiple combination sets, and the model's operation is divided into various layers; it is then passed through the phase of preprocessing and features extraction based on deep and text features extraction techniques including Word2Vec and GloVe, BoW, and TF-IDF respectively; the extricated textual attributes are then given to several ML models LR, SVM and RF while the features derived from word embedding models are provided to a custom CNN for classification; finally, the results are evaluated based on several execution assessment metrics.

The rest of the paper is as follows: Section II provides a literature review of the techniques used by previous works for Islamophobic news classification and text analysis. Section III provides insights of the proposed work of this research study. All the experiments conducted along with their results and performance evaluations are listed in Section IV. Section V provides a discussion of results obtained and finally, Section VI concludes the proposed work.

II. Related Work

In recent years, there has been a rise in the quantity of study looking at different religious organizations in terms of their racial makeup, religion, gender, representation, and degree of equality. Numerous studies have been conducted on the topic of fake news because of the surge in hate speech, online publishing, and social media content that is directed towards Muslims and Islam worldwide [13]. However, a few studies have been conducted on the automatic detection of anti-Islamic content. A brief synopsis of these investigations is provided in the material below.

Mehmood et al. [14] performed the hate speech identification and isolation from 1290 tweets that were part of a publicly available twitter collection. Out of the 1290 tweets gathered, 566 are classified as unfavorable and 724 as positive. Preprocessing processes for the raw data include case folding, tokenization, removing superfluous words, cleaning, and breaking words rectification. 1D-CNN and other RNN variations are created and used to conduct feature ex-traction and categorization. 80% of the data is utilized for model training, while the remaining 20% is used for model testing. Several RNN and CNN combinations are used to get the findings. While using the CNN with Bi-LSTM, which is the most accurate method, the maximum accuracy of 90% is achieved. Chandra et al. [15] presented a tweet based CoronaBias dataset to do the analysis of social media data for Islamophobic content. Between the months of February and March 2020, CoronaBias included 410,990 tweets, and every single one of them had terms relating to Islam or Muslims. BERT and SVM are used to annotate the data. A total of 2000 good and hate tweets are retrieved for model training, and the PELT method is used to do temporal analysis on them. Positive matrix factorization, which increases the model's capabilities, is used for feature derivation. The results are studied, compared, and tracked using graphical representations and a few metrics, and it can be shown that the proposed BERT model provides the best accuracy results with a rate of over 85%, which is higher than the SVM's rate of 79%.

In this work [16], Khan et al. gathered twitter data for the first six months of 2020. The 17,228 tweets that were gathered were annotated by skilled humans after going through necessary pre-processing procedures. The experiments are carried out using deep and textual feature extraction methods. Additionally, ML and DL approaches are used to classify tweets into different polarity categories. Because of embedment of deep and text attributes, the SVM model offers an accuracy more than 95% on the validation data. Alraddadi et al. [17] categorized text utilizing sentiment and text analysis techniques. Arabic dataset obtained for the 3 months of 2021is based on news articles and publications from famous search engines. The Octoparsescraing program is used to assemble the relevant data into an Excel spreadsheet. The input data is subjected to pre-processing methods while for feature selection, n-grams and term frequency computation models are used. Resultant data is sent to multiple ML algorithms for feature creation and data categorization based on labels. Results are derived using the model while considering several performance monitoring standards after data is divided into a 70-30% division. For word-level, balanced, and non-balanced datasets, the TF-IDF and SVM combination yields successful results with accuracy above 97%. Vidgen et al. [18] examined data from social media to categorize the content that contains strong and mild Islamophobic hate content. Tweets more than 100 million are collected from Twitter for the entire year of 2017 and the first half of 2018. The final dataset comprises 1300 tweets after 4000 tweets from this data collection are picked as a training batch and manually annotated. Several features are generated using deep and text extraction methods which are then supplied to ML and DL models for categorization. DL model delivers the best outcomes and perform almost equally, with accuracy of 71.14%. The results are obtained for various data sets, and they are afterwards further evaluated using certain metrics. The authors [19] used AI methods to analyze the data from social channels. The data utilized is based on comments from various writers' and authors' personal blogs and is collected based on several keywords. The findings, which were generated with the use of various execution criteria, demonstrate that the accuracy of the RF and bagging classifiers is practically identical at 0.66%, and pre-processing did not increase the results any further.

The authors in [20] examined tweets about Islamophobia from the time when the Christchurch incident occurred in 2019. The study's data is based on 3100 deleted tweets from the time of mishap. Tokenization, stop word removal, and scraping are a few of the preparation and refining processes the data goes through. NB and SVM models are used in the classification procedure. The results are based on both the unbalanced set and the data labelled using the Valence Aware Dictionary and Sentiment Reasoner. Along with the two ML models already described, the synthetic minority oversampling method is employed to derive and compare results. In the work [21], the authors also examined tweets for the trace of Islamophobic material. They gathered 150,000 tweets from 2018 and professional annotators manually categorized them into polarity ratings. Before sending the data to the ML-models, pre-processing is performed. Both in terms of accuracy (98.1%) and processing time, the RR classifier outperforms the Bayesian classifier. Gonzalez-Pizarro et al. [22] used contrastive learning to study the hostile attitudes on political data acquired from Papasavva. 134,5 million political postings from June 2016 to November 2019 are included in the data. In addition to this data, a collection of 5,859, 439 pictures were also collected from Zannettou. The data is given ratings, and after going through a few pre-processing steps, TF-IDF is utilized to look for hate speech content. For the extraction of features, all photos with a cosine similarity index of at least 0.3 are chosen and compared with the textual data using several API’s. With precision up to 80%, the results show 69,000 antisemitic and 100,000 hate content from the entire data collection.

From the above discussion, it can be observed that some works have utilized embedding models, others have made use of n-grams for the derivation of useful data attributes. Also, there is a huge gap in Islamophobic content detection because to date only the above-mentioned studies have been conducted. Moreover, the results have been concluded based on either by using ML or DL models. Taking the lead from this, this study’s conducted work focuses on implementing the combination of all for a better comparison of each model’s performance on the currently utilized Islamophobic news data.

III. Proposed Methodology

The proposed research focuses on identifying and categorizing social media corpora that are associated with Islamophobia. The dataset of extreme and hateful tweets against Muslims and the Islamic faith was gathered from Twitter and other internet sources, pre-processed, cleaned, and subjected to several word embedding and n-gram algorithms, such as Word2Vec, Glove, TF-IDF, and BOW, for analysis. RF, SVM, LR, and a deep model CNN are some of the existing ML-algorithms that are used in the final step of data categorization. Accuracy, K-fold cross-validation, and F1-score are a few assessment metrics used to analyze the outcomes. Fig. 1 represents a detailed flow diagram of the proposed model.

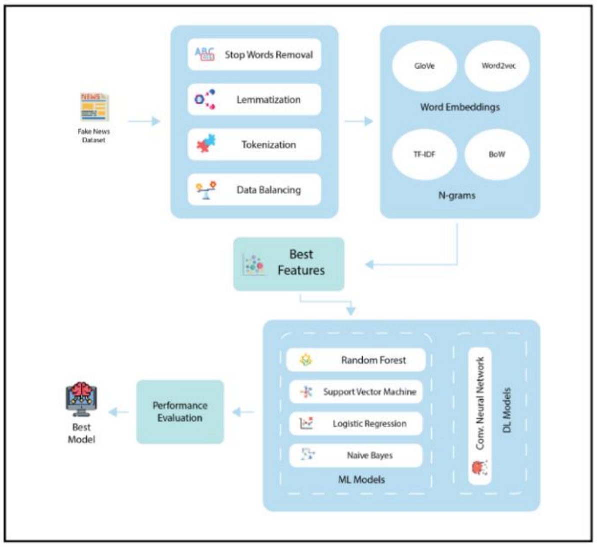

Fig. 1. Proposed framework.

A. Dataset

Tweet dataset exploited in the study is based on tweets and is not focused on a specific country to track the spread and effects of Islamophobia globally. Based on lexicons from Hate-base, some pre-defined hashtags were utilized for data retrieval during first six months of 2020 [23]. The data is scattered since it doesn't concentrate on user accounts, but it is nevertheless retrieved using an impartial technique. The 8438 English-language tweets in the study's dataset were pre-annotated by three annotators who are fluent in the language. The tweets were labelled into one of the three pre-defined categories namely Anti-Islamic, about Islam but having positive sentiment, and neither about Islam nor having any bad sentiments about Islam. The editors worked with data that was completely devoid of user and tweet identities. With considerable care, the annotators assigned the labels, and in cases of a tie, consensus casting ballots assignation was also employed. Table I provides an overview of data statistics.

B. Dataset Preprocessing and Balancing

Data preparation serves as the foundational stage for every classification work since it prepares, cleans, and removes ambiguities from the data [24]. Conversion of alphabets into smaller notations, end word rectification, hyperlink removal, removal of false full stops and half-sentences, tokenization and lemma generation are some of the preprocessing techniques used in this study. As a result of the utilized unbalanced data, created randomly using a variety of sources, the proposed model may not perform well [25]. To address this problem, the class with the greatest number of tweets is chosen, and those from the other two classes are replicated at random to keep the frequency of tweets across all classes under consideration equal. The experiments and findings derivation use the balanced data from this point forward. Following data balancing, the total number of tweets in each class is shown in Table II.

TABLE I. OVERVIEW OF DATASETS ATTRIBUTES

Attribute	Value	Attribute
Total tweets	8438	Total tweets
Tweets containing Islamophobic content	2485	Tweets containing Islamophobic content
Tweets about Islam but not Islamophobic	2398	Tweets about Islam but not Islamophobic
Tweets neither Islamophobic nor Islamic	3555	Tweets neither Islamophobic nor Islamic
Tweets language	English	Tweets language

TABLE II. TWEET COUNT FOR EACH TWEET CLASS

Label	Tweets
Islamophobic	3554
About Islam Not Islamophobic	3554
Neither Islamophobic nor About Islam	3555

The created vocabulary magnitude for the balanced data after pre-processing seems to be 17861 unigrams with the distribution of tweet-length set at 14 words each tweet. After pre-processing the data with eight words per tweet, the same magnitude drops to 16580 unigrams.

C. Feature Extraction

After preprocessing the data and balancing it, the next phase to be performed is feature extraction in which data is converted into vector attributes for the ML and DL models to interpret it. Two types of features are derived from dataset including word embedding based deep features and textual features which are described in next sections.

1) Word embedding: Word embedding is used to convert and represent textual data comprised of words into a vector and mathematical representation [26], [27]. Many models are available for this purpose, but in this study, we utilized the pre-trained GloVe from Stanford NLP and Wor2vec from Google news vectors. The GloVe is an unattended learning algorithm utilized for extracting word embeddings from the input data corpus based on the global word co-occurrence matrix. It is trained on global statistics of words included in a huge corpus compiled from online sources and when applied to any data, it directly obtains information about the words occurring frequently in that data and maps the words into vector spaces [28]. It has been widely utilized in text classification problems to derive features [29]– [31] and pass them on to classification models. It is based on the Log Bilinear (LBL) model that operates on the principle of weighted least squares [32] as Eq. (1) depicts.

$$d_a . d_b = logP\left(\frac{a}{b}\right) \tag{1}$$

Here, $d_a . d_b$ represent the weight density that any two data points carry within the corpus.Prepresents the co-occurrence probability of both the points. The complete working logic behind GloVe is represented in Eq. (2).

$$l = \sum_{a,b=1}^{n} f\left(G_{a,b}\right)\left(d_a^t d_b - \log G_{a,b}\right)^2 \tag{2}$$

where, l represents loss function, $f(G_{a,b})$ is the function that maps least-squares between both the points starting from 1 to onwards, $d_a^t d_b$ is the density of both the data points concerning time t, and $log\, G_{a,b}$ is the log of the function containing the square computation of data points. Word2vec is also a word embedding technique that works based on shallow neural networks and utilizes the skip-gram method to achieve this functionality [33]. It creates vectors of textual data included in the corpus based on the frequency of documents and their co-occurrence matrix. Eq. (3) demonstrates how Word2vec uses the skip-gram approach to do computation.

$$\frac{1}{T}\sum_{p=1}^{D}\sum_{-s\leq a\leq s, a\neq 0} log\, prob(word_{p+1}|word_t) \tag{3}$$

where, D is the corpus proportionality, p is the position of $word_t$ in data, $\log prob(word_{t+1}|word_t)$ indicates the logarithm of $word_t$ concerning incrementing positions and co-occurrences within the document [34]. In the proposed work also, the preprocessed data is delivered to both GloVe and Word2vec models, and the features derived by them are later given a customized CNN and the results are evaluated.

2) N-gram methods: N-grams are any sequence of word tokens in each data where n = 1 denotes unigram, n = 2 denotes bigram, and so on. An n-gram model can compute the probability of n-grams within a data corpus and provide a prediction. The use of such models becomes useful in text classification tasks where there is a need to count the number of specific words included in the vocabulary from the corpus [35]. Such a metric is the TF-IDF, which assesses how closely a word in a catalogue is connected to its mood or meaning. It determines the frequency of each relevant text and generates phrases with an inverse frequency of those that appear often throughout multiple articles [36]. TF-IDF analyzes document terms frequency in each document [37] represented in Eq. (4).

$$weight_{a,b} = freq_{a,b}^{t} x \log\left(\frac{N}{freq_a}\right) \tag{4}$$

where, $weight_{a,b}$ indicates the total weightage carried by the data two points, $freq_{a,b}^{t}$ calculates the appearance ratio of data point a in b, N shows the total documents count included in the corpus, $\log(\frac{N}{freq_a})$ computes the log of all included documents with the frequency of data point a. The textual material to be categorized can also be used by BOW to extract valuable properties. It operates using a specified vocabulary and uses that vocabulary to seek for the frequency of specific terms in the relevant material. The model only deals with whether familiar words occur in the document and has no concern about where they occur and it provides the histogram of given words within the data which can be easily given the classifiers [38]. BOW performs the creation of bags based on words based on Eq. (5).

$$doc_b = \sum_{a=1}^{N} weight_a^b\, xweight_a \tag{5}$$

where, doc_b indicates the document housing the targeted data point b. $weight_a^b$ shows the numerical weights of the repeating word for concerned feature point b included in the document. $weight_a$ indicates the weight of frequent word a that we are looking for in this scenario [39]. In the proposed work, both TF-IDF and BOW are used for the derivation of features from the preprocessed dataset. The extracted features from both these models are tested and classified using a set of four ML classifiers for classification.

D. Fake News Classification

After completing all the stages, the word embedding techniques' feature sets are fed into a DL algorithm called CNN, and feature sets derived from N-grams are directed to ML distributors. To perform the categorization against the derived attributes, the proposed work uses four ML-Classifiers: RF, SVM, LR, and NB well as a DL-based CNN that includes embedding, convolutional, max-pooling, and SoftMax layers.

IV. Experiments and Results

The suggested methodology uses word embedding and n-gram techniques to extract valuable characteristics from the input textual data based on Islamophobic news from social media, before performing classification using four ML algorithms and a CNN model. Word embedding features are first identified using a deep CNN, and then n-gram method-based features are sent to the four ML-algorithms for classification in a series of experiments based on word embedding, n-grams, ML, and DL model combinations. After balancing the dataset, each experiment is run, and the results are analyzed using a variety of performance analysis standards, such as recall, f1-score, 10-fold accuracy, and precision. In the first experiment, SVM is used to assess n-grams-based features. Table III mentions the results of SVM-TF-IDF and SVM-BOW with assessment metrics.

SVM is a ML classifier that is employed for the high-dimensional feature mapping process. Most frequently, it is used to categories and transforms data so that it may be used to sort records into their correct classifications. Using a renowned sklearn linear model package and n-gram based textual feature extraction techniques; we applied it to our categorical islamophobia data in the Python programming environment. 90% and 10% of the dataset are used, respectively, for training and testing the model. The number of folds is set to 10, and the maximum number of iterations is equal to 10000, for the k fold cross-validation procedure to test the model. As can be seen through Fig. 2, upon maintaining cross substantiation of 10-folds, it can be observed that the SVM in combination with the BOW technique obtains an accuracy of 97.3% as opposed to the 97.1% obtained by the SVM-TF-IDF.

In the following experiment, the RF classifier is given the same n-gram-based characteristics for the identification of Islamophobic material. Since the three used ML models are all the standard variety, we additionally used an ensemble model called Random Forest to further investigate the outcomes. Since Decision Tree is not an ensemble approach and produces almost identical hyperparameters as RF, we opted against using the most popular ML model. The library used to integrate the model into our environment is called sklearn ensemble, and the experiments employing this model are carried out using the Python programming language. 90% of the dataset is used to train the model, and 10% of the dataset is used to test it using k fold cross-validation with a fold size of 10 and 200 estimators.

The outcomes of the RF-TF-IDF and RF-BOW, with the identical assessment metrics, are shown in Table IV. Additionally, it can be noted that in this instance, when used in conjunction with the BOW model, the RF obtains an accuracy of 94.1% as opposed to the 91.4% obtained by the RF when utilizing TF-IDF when 10-fold cross-validation is maintained. As shown in Fig. 3, the RF and BOW combination also obtains greater f1-score, recall, and precision values than the RF-TF-IDF model.

TABLE III. Results of TF-IDF and BOW Features with SVM

PEM	**SVM – TFIDF**	**SVM - BoW**
10-Fold Accuracy	0.97	0.97
Precision	0.97	0.97
F1 Score	0.96	0.97
Recall	0.96	0.97

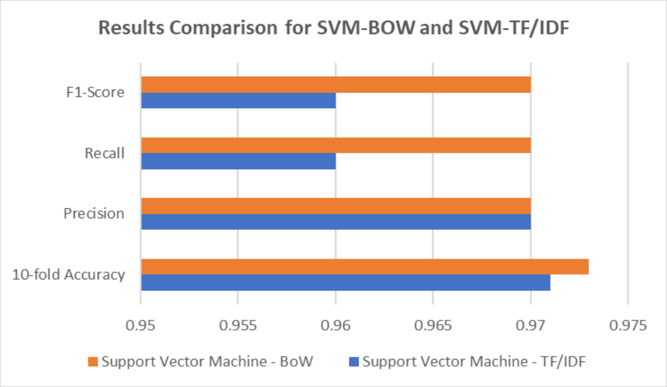

Fig. 2. Results comparison for SVM-BOW and SVM-TF / IDF.

TABLE IV. Results of TF-IDF and BOW Features with RF

PEM	**RF – TFIDF**	**RF -BoW**
10-Fold Accuracy	0.91	0.94
Precision	0.92	0.94
F1 Score	0.92	0.93
Recall	0.92	0.93

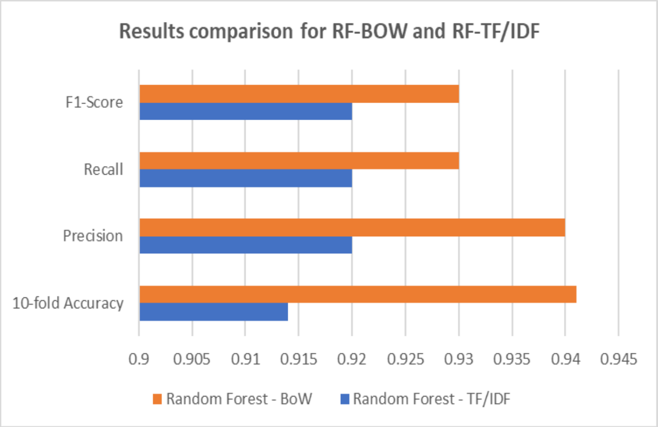

Fig. 3. Results comparison for RF-BOW and RF-TF / IDF.

TABLE V. RESULTS OF TF-IDF AND BOW FEATURES WITH LR

PEM	LR-TF-IDF	LR-BOW
10-Fold Accuracy	0.96	0.97
Precision	0.97	0.98
F1 Score	0.97	0.98
Recall	0.97	0.98

The experiment that follows uses an LR classifier to conduct classification based on the same n-gram characteristics as the ML models discussed before. Categorical data categorization in ML also employs LR algorithm. The finding of connections between probabilities and the outcome of the anticipated record is the first step in this model's major operation. We used this Python-based model to train and evaluate itself against our categorical data. 90/10 ratio is maintained for model's training and evaluation. Sklearn is the name of the library that was used to import this model into the experimental workspace. The outcomes of LR-TF-IDF and LR-BOW using the identical execution standards are shown in Table V

When TF-IDF linked model is maintained, BOW beats it by obtaining superior accuracy of 97.3 percent as opposed to 96.6 percent for the latter when coupled with an ML-classifier, in this instance LR. In addition, as shown in Fig. 4, LR-BOW outperforms LR-TF-IDF in all other performance metrics.

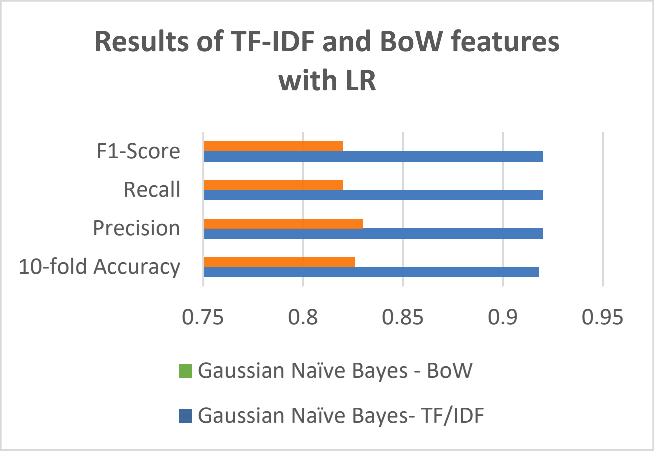

Fig. 4. Results comparison of TF-IDF and BOW with LR.

The GNB is used to classify with the features as an input, like in prior experiments, in this last experiment while utilizing an ML-classifier. Through its several iterations, which treat each input as an independent variable and forecast its likelihood, it aids in the rapid categorization of data. This technique is implemented in our codebase using the sklearn naive bayes package. For training and testing, the algorithm's Gaussian variant is employed, with data splits of 90% and 10%, respectively. The GNB-TF-IDF and GNB-BoW findings are displayed in Table VI.

When 10-fold cross-validation is maintained, TF-IDF outperforms its counterpart in this instance and obtains an accuracy of 91.8 percent as opposed to the 82.6 percent attained by the BOW-based model. In comparison to GNB-BOW, GNB-TF-IDF also outperforms it in all other performance metrics, as shown in Fig. 5.

The features retrieved by the word embedding models GloVe and Word2vec are further evaluated using a bespoke CNN after the implementation of four ML models with derived n-gram features. This model, which is a kind of deep neural networks, is primarily utilized for the accurate and quick categorization of vectorial data. The same data split utilized by ML algorithms is used to train and test this model when it is integrated into our software. The CNN is first trained and tested using Word2vec features with a batch size of 10 for model training and 32 epochs for testing. The number of epochs is kept at 5, and the batch size is kept at 32 for the k-fold cross-validation. Fig. 6 shows the training and validation loss for CNN using Word2vec.

TABLE VI. RESULTS OF TF-IDF AND BOW FEATURES WITH GNB

PEM	GNB-TF-IDF	GNB-BOW
10-Fold Accuracy	0.91	0.82
Precision	0.92	0.83
F1 Score	0.92	0.82
Recall	0.92	0.82

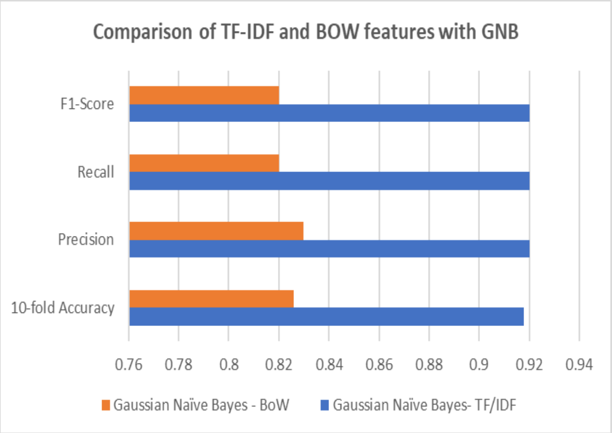

Fig. 5. Results comparison of TF-IDF and BOW with GNB.

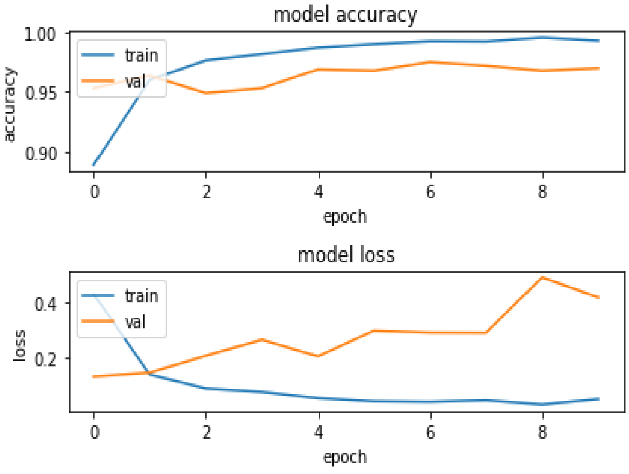

Fig. 6. Training and validation loss for CNN using Word2Vec.

Fig. 7 shows the training and validation loss for CNN using GloVe.

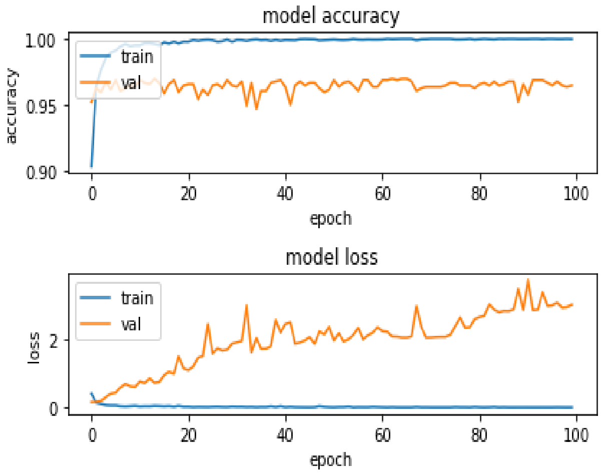

Fig. 7. Training and validation loss for CNN using GloVe.

Results for both embedding models with CNN are displayed in Table VII based on previously applied performance metrics.

TABLE VII. RESULTS OF WORD2VEC AND GLOVE FEATURES WITH CNN

PEM	CNN-Word2Vec	GNB-GloVe
10-Fold Accuracy	0.96	0.96
Precision	0.97	0.96
F1 Score	0.97	0.96
Recall	0.97	0.96

As observed in Fig. 3, Fig. 4, and Table VIII, CNN works a little bit better with Word2vec than GloVe because it obtains a better 10-fold accuracy and retains a higher evaluation rate. Table VIII gives a summary of all the experiments that were done above and gives a more comprehensive perspective of all the outcomes that were inferred.

TABLE VIII. RESULTS OF ML AND DL-MODELS WITH CORRESPONDING WORD EMBEDDINGS AND N-GRAMS

PEM	SVM-TFIDF	SVM-BOW	RF-TFIDF	RF - BOW	LR-TFIDF	LR-BOW	GNB-TFIDF	GNB-BOW	CNN-Word2vec	CNN-Glove
10-Fold Accuracy	0.97	0.97	0.91	0.94	0.96	0.97	0.91	0.82	0.96	0.96
Precision	0.97	0.97	0.92	0.94	0.97	0.98	0.92	0.83	0.97	0.96
F1 Score	0.96	0.97	0.92	0.93	0.97	0.98	0.92	0.82	0.97	0.96
Recall	0.96	0.97	0.92	0.93	0.97	0.98	0.92	0.82	0.97	0.96

V. DISCUSSION ON RESULTS

The findings of each experiment carried out for the planned study are covered in detail in the preceding section. It is clear from the trials on the characteristics that the n-gram models TF-IDF and BOW were able to extract using four ML-models that BOW outperforms TF-IDF in these scenarios. BOW outperformed its rival in terms of accuracy and other performance metrics when it was categorized using SVM, RF, and LR. Only when used in conjunction with GNB models did TF-IDF perform better. This demonstrates why it is preferable to use BOW-based features for the planned task.

The model also produced respectable results when Word2vec and GloVe word embedding features were classified using a custom CNN. The CNN-Word2vec model emerged as the superior one of the two because, as seen in Fig. 8, it performed better across the board.

The performance comparisons for the independently developed ML and DL models with n-gram and word embedding schemas are covered in the section above. However, this study demonstrates that ML-models typically outperform CNN in terms of categorization of the Islamophobic data utilized for this experiment. This shows that both SVM and LR outperform CNN at their maximal performance levels. Using both ML models stated, an average accuracy of 97 percent is attained, which is much higher than the 96.4 percent achieved by CNN.

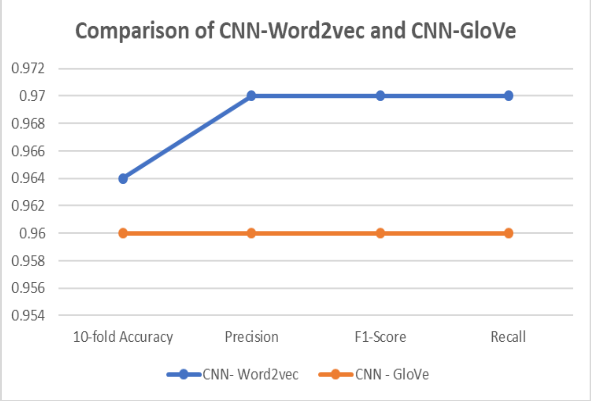

Fig. 8. Performance comparison of Word2vec and GloVe with CNN.

While the results of proposed work are quite encouraging, its performance is highly dependent on the characteristics of the data that can be further investigated in the future research work.

VI. CONCLUSION

It is alarming to see how hateful, exaggerated, extremist, and misunderstood misinformation about fake news and its impact on society is spreading on social media. Such material is accessible to a global audience, and as a result, various communities may be the target of harsh measures. The suggested project focuses on classifying such fake news content using data from Twitter. It uses several data cleaning and improvement procedures to refine the data. The implementation of Word2vec, GloVe, TF-IDF, and BOW word embedding, and n-grams methods follows to extract key characteristics from the data. Finally, four ML algorithms and a CNN created by the customer are used to classify the data. On average, the ML models outperform CNN and produce superior outcomes. The assessment of DL algorithms on this data might be done in the future using more DL algorithms like LSTM and RNN. Bert is the most recent DL feature extraction model based on a transformer that is becoming increasingly prominent in the field of sentiment analysis on textual data. While the results of proposed work are quite encouraging, its performance is highly dependent on the characteristics of the data that can be further investigated in the future research work.

i-Tech: Empowering Educators to Bring Experimental Learning to Classrooms

A 360° Content Creation Tool

Amani Alqarni[1], Jieyu Wang[2], Abdullah Abuhussein[3]
Information Technology and Security Department, Jazan University, Jazan, Saudi Arabia[1]
Department of Information Systems, Saint Cloud State University, St. Cloud, MN, USA[2, 3]

***Abstract*—The integration of technology in education has gained significant attention, with Virtual Reality (VR), Augmented Reality (AR), and 360° VR emerging as transformative tools for enhancing student learning experiences. Despite their potential benefits, these immersive technologies have not achieved widespread adoption in education. Educators face numerous challenges in finding suitable 360° content for their courses and integrating complex content creation tools. Creating educational 360° content often involves hiring programmers or mastering intricate programming techniques, which can be time-consuming and daunting. Educators also struggle with finding platforms to host, edit, segment video content according to topics, and add subtitles and translations to their 360° videos. To address these challenges, this paper presents the implementation and evaluation of a user-friendly prototype tool with a step-by-step graphical user interface. This high-fidelity prototype assists educators in uploading 360° content, segmenting it into chapters or topics, incorporating questions or requirements within video segments, adding subtitles and translations, and facilitating content sharing among educators. This design aims to assist teachers in publishing their 360° content while reducing the complex VR programming for them. It enables them to integrate immersive learning in their classrooms with ease. The final goal is to promote greater adoption of 360° VR content in education and enhance learning outcomes.**

Keywords*—Virtual reality; 360° video; user behavior analysis; content delivery; immersive media; education; technology in education; instructional design; human-computer interaction

I. Introduction

Now-a-days, video content is employed in various forms to enhance the learning experience. As the barriers to accessing 360° video technology diminish, it has become increasingly effortless to engage with 360° content. In contrast to traditional media, 360° media offers a fully immersive and interactive simulated environment, providing students with a unique experiential perspective. Furthermore, this immersive approach helps minimize or even eliminate distractions that students may encounter.

While the use of 360° technology in education is gaining momentum, there is still ample room for improvement in this domain. The complexity involved in creating, processing, and disseminating 360° educational content, and making it accessible and beneficial for public consumption, contributes to this ongoing need for refinement. Undoubtedly, the integration of 360° technology in education presents educators with numerous challenges that may deter them from fully embracing this otherwise valuable tool. These challenges encompass both pedagogical and didactical aspects, such as effectively planning and designing virtual classrooms. Additionally, educators encounter various technical hurdles that impede the widespread adoption of 360° technology. These technical challenges include: (1) locating reliable resources that provide guidance on creating and publishing 360° media, (2) navigating the intricacies of these tools, particularly for novice computer users, (3) grappling with the time-consuming and labor-intensive process of designing and publishing content using multiple tools and frameworks, (4) addressing issues pertaining to subpar sound or image quality in the published media, (5) limited access to appropriate hardware and devices for capturing and viewing 360° content, and (6) insufficient bandwidth and network infrastructure to stream high-quality 360° videos in educational settings. (7) Moreover, concerns about data privacy and security when using immersive technologies in educational settings further add to the challenges educators face in adopting and implementing 360° technology.

This paper presents a prototype tool called i-Tech that aims to enable educators to process and publish their 360° content and share it with their students in one place. The tool provides a user-friendly step-by-step graphical interface, assisting educators in uploading their 360° content, segmenting it into chapters, incorporating questions/requirements before video chunks, adding subtitles to the video content, and making their content available to other educators in the field. This work aims to increase educators' adoption of 360° VR content in education and improve learning outcomes. While i-Tech is currently in the prototype stage, its purpose is to demonstrate the potential of such a tool and its impact on educational practices.

II. Literature Review

The utilization of VR, 360°, and mixed reality content in the field of education is not a new domain; it has been extensively explored in various research studies using different methodologies. In this section, we will delve into the concepts and applications of 360° media, as well as the incorporation of virtual reality (VR) and augmented reality (AR) technologies in educational settings. Furthermore, we will examine the challenges encountered in the design and development of 360° technology and explore existing endeavors aimed at providing educators with tools to facilitate the creation and dissemination of their 360° content online.

A. Background on 360° Media

The demand for enhanced immersion in virtual simulated environments has spurred the advancement of immersive technologies, leading to the emergence of novel forms of virtual reality (VR), augmented reality (AR), and 360° technologies. These technologies have revolutionized training programs by providing learners with engaging experiences that utilize multiple senses, such as sight, hearing, and touch, thereby facilitating effective knowledge acquisition. Among these advancements, 360° video technology has emerged as a promising and cost-effective solution for creating interactive virtual reality applications with immersive capabilities.

360° videos also referred to as immersive or spherical videos are filmed using a specialized camera that captures a panoramic view spanning 360 degrees. These cameras feature lenses positioned either on the top to capture the entire surroundings or on multiple sides to capture a comprehensive view from top to bottom and left to right. The captured images are then stitched together to create a seamless and immersive video experience. In contrast to traditional videos, which are limited to the camera's focal point, 360° videos provide viewers with the ability to explore and observe everything within the camera's range, resulting in a fully immersive viewing experience.

360° videos can be obtained through two main approaches: capturing real-life landscapes or creating computer-generated panoramas using 3D computer graphics software tools such as Blender [16], [1]. In the first approach, a specialized camera captures the entire 360° view of a physical environment. This allows for an immersive representation of real-world locations and events. Alternatively, in the second approach, 360° computer-generated panoramas are generated using software tools like Blender. These panoramas are created using 3D modeling and rendering techniques, providing the flexibility to design and visualize virtual environments with complete control over the content and scenery. Both methods contribute to the production of captivating 360° videos that offer viewers a rich and immersive visual experience.

The popularity of the 360° video format surged in early 2015, primarily due to its integration with YouTube. YouTube introduced support for importing and viewing VR videos in March 2015, making it accessible to a wider audience. Following in YouTube's footsteps, Facebook also embraced 360° videos and launched support for this format in September of the same year. In March 2017, Facebook revealed that over one million 360° videos had been uploaded to its platform, highlighting the growing interest and engagement with this immersive video format. Additionally, Vimeo, a prominent video-sharing website, joined the trend and introduced support for 360° videos in March 2017, providing another platform for creators to showcase their immersive content. These developments have contributed to the widespread adoption and availability of 360° videos across various online platforms.

In a 360° video, viewers are no longer limited to a fixed frame; they have the freedom to control the camera angle and explore the entire environment. This interactive viewing experience allows viewers to watch the video from multiple perspectives, offering an active engagement rather than a passive observation limited to the director's point of view. To enjoy a 360° video, viewers can use various devices such as personal computers, smartphones, or dedicated head-mounted displays. On computers and touch screen devices, viewers can navigate within the video by using a mouse or touch gestures. Smartphones equipped with internal sensors like gyroscopes allow users to pan the video based on the orientation of their device. For a more immersive experience akin to virtual reality, viewers can use stereoscope-style enclosures like Google Cardboard or Samsung Gear VR. These enclosures hold the smartphone and incorporate lenses that enable viewers to view the 360° video in a more immersive and engaging manner, utilizing the phone's display rather than a dedicated display found in virtual reality headsets.

B. Benefits and Challenges of 360° Videos in Education

The following literature review provides a comprehensive overview of the use of 360° videos, virtual reality (VR), and augmented reality (AR) in education. It explores the existing research and empirical studies to understand the potential benefits, challenges, and implications of integrating these immersive technologies in educational settings. Several authors have made significant contributions to the field of 360° videos, virtual reality (VR), and augmented reality (AR) in education. Their works have shed light on the potential benefits and challenges of integrating these immersive technologies into educational settings. Some important works include "If and how do 360° videos fit into education settings? Results from a scoping review of empirical research" [2] which presents a comprehensive examination of the integration of 360° videos in educational settings. Through a scoping review of empirical research, the study explores the various ways in which 360° videos are utilized and their effectiveness in enhancing educational experiences. The findings reveal that 360° videos have the potential to enhance student engagement, information retention, and the overall effectiveness of the learning process. However, the review also highlights certain challenges such as motion sickness and the limited availability of specialized 360° videos for educational purposes.

This work, titled "The Potential of 360° Virtual Reality Videos and Real VR for Education—A Literature Review" by [3], explores the potential of 360° virtual reality videos and real VR in education. It examines existing research and highlights the benefits and applications of these immersive technologies in educational settings.

The authors of [4] conduct a comprehensive examination of the research conducted on 360° video and its applications within the realm of education. Their work offers valuable insights into a wide range of studies carried out in this area, shedding light on the diverse potential uses of 360° video technology in educational settings.

Authors of the paper "Educational 360° Videos in Virtual Reality: a Scoping Review of the Emerging Research" [5] offer a comprehensive overview of the current research landscape surrounding educational 360° videos in virtual reality. The paper delves into the effectiveness and impact of these videos in enhancing learning experiences while examining the associated benefits and challenges. With its valuable insights, the paper serves as an essential resource for educators, researchers, and practitioners seeking to integrate immersive technologies, such as 360° videos, into educational settings.

Collectively, these works contribute to our understanding of the potential benefits and challenges associated with the integration of 360° videos, VR, and AR in education, providing valuable insights and guidance for educators and researchers in this field.

C. 360° Videos Challenges

360° videos pose a range of challenges for developers and users alike. Developers face the primary challenge of complexity when producing high-quality 360° videos. This complexity arises from the need for specialized equipment like multi-camera rigs and intricate post-processing techniques, adding both intricacy and cost compared to traditional videos [6].

Another challenge developer’s encounter is the increased bandwidth and storage requirements of 360° videos. Due to the expanded field of view, these videos typically have larger file sizes, demanding higher bandwidth for streaming or downloading. Managing encoding and compression is crucial for developers to ensure optimal streaming and playback experiences while maintaining video quality and reducing file sizes [7].

Platform compatibility poses an additional challenge for developers. Ensuring seamless performance across various platforms, devices, and operating systems is demanding. Developers must account for different video codecs, players, and technical specifications to provide a consistent experience to users across diverse environments [8].

From a user's perspective, in addition to compatibility issues, internet speed, device limitations, and bandwidth constraints, one of the significant challenges of 360° videos is the hardware requirements. Enjoying a high-quality 360° video experience often demands specialized hardware like virtual reality (VR) headsets or powerful smartphones. This requirement may limit accessibility for users who lack the necessary equipment.

Motion sickness is another challenge users may encounter when engaging with 360° videos. The immersive nature of these videos and continuous camera movements can lead to discomfort or motion sickness, resulting in shorter engagement durations and potentially impacting the overall user experience [9].

Limited availability of diverse and high-quality 360° video content compared to traditional videos poses another challenge for users. Finding compelling 360° videos on preferred platforms can be difficult, hindering overall enjoyment of the medium [10].

Interacting with 360° videos presents a learning curve for users, especially those unfamiliar with the technology. Understanding navigation controls and effectively exploring the content may require time and patience to fully grasp [11].

Users may also have concerns regarding processing power and battery life [11]. Rendering and playing back 360° videos demand more processing power, potentially impacting device performance and battery life. This concern is particularly relevant for users utilizing battery-powered devices such as smartphones or VR headsets.

Despite these challenges, continuous technological advancements, improved production workflows, and the growing adoption of 360° video content can help mitigate these obstacles and provide a more seamless and accessible experience for both developers and users.

In addition to the aforementioned challenges, adopting 360° video technology in education is faced with the following challenges:

Pedagogical integration: It is essential to integrate 360° videos into the curriculum in a meaningful and pedagogically sound manner. Teachers need to identify the appropriate learning objectives and design activities that align with the content of the videos [12].

Assessment and evaluation: Assessing student learning and evaluating the effectiveness of 360° videos as an educational tool can be challenging. Traditional assessment methods may need to be adapted or augmented to incorporate the unique aspects of 360° video experiences, such as student interaction and exploration within the video environment [13].

Teacher training and support: Integrating 360° videos into the curriculum requires teachers to have the necessary skills and knowledge to effectively utilize this technology. Providing comprehensive training and ongoing support to educators is crucial to ensure they can maximize the educational benefits of 360° videos and incorporate them seamlessly into their teaching practices [14].

These challenges highlight the importance of addressing pedagogical considerations, developing appropriate assessment methods, and providing adequate training and support to teachers. By tackling these challenges, educational institutions can harness the full potential of 360° videos as a powerful educational tool for immersive and interactive learning experiences.

Therefore, the design aims to alleviate users' time and effort regarding technical challenges and streamline the process of creating VR classes. We also evaluated our prototype platform, aligned with Norman's usability goals concerning effectiveness, efficiency, learnability, memorability, error prevention, and user satisfaction. We aimed to gain a comprehensive understanding of the participants' experiences with our platform and identify areas for future software production improvement.

III. I-TECH DESIGN AND IMPLEMENTATION

A. Design of the Platform

Our design goal for i-Teach (Immersive Teaching Enabler And Content hosting) is guided by Norman's design principles [15]. The primary objective is to alleviate users' concerns regarding technical challenges and streamline the process of creating VR classes, thereby saving their time and effort. Our team consists of one investigator who collaborated closely with a recruited programmer to handle the implementation aspect. Additionally, we have two UX investigators dedicated to designing and evaluating the platform. Throughout an entire semester, we conduct weekly meetings to brainstorm, discuss, and refine the platform's design, ensuring it meets the needs of educators and enhances their immersive teaching experience.

Our prototype platform offers a streamlined procedure comprising five steps to facilitate the uploading, editing, and publishing of 360° videos. Fig. 1 provides a visual representation of these steps. The sequential process is as follows:

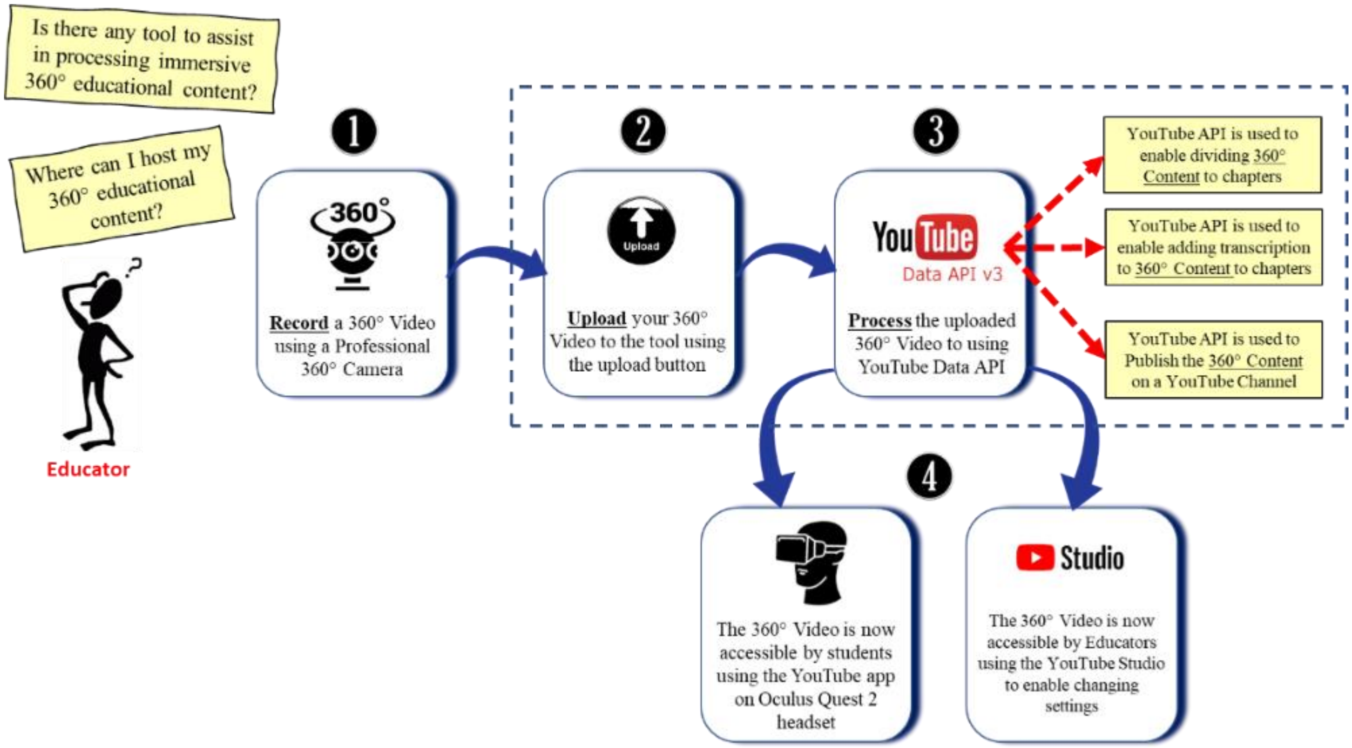
- Get started: Users initiate the process by accessing our platform and starting the video upload procedure.
- Choose the video: Users select the desired 360° video file from their local storage or designated location.
- Entitle the video: Users provide a title or description for the video, furnishing relevant information to enhance its visibility and searchability.
- Video segmentation: As needed, users can opt to segment or divide the video into smaller segments to facilitate easier processing and management.
- Upload the video: Users finalize the process by uploading the 360° video file to our platform, ensuring its availability for subsequent editing or publishing.

By following these user-friendly steps, our platform empowers users to efficiently manage and publish their 360° videos, providing them with a seamless experience.

The landing page of i-Tech offers users a convenient file upload feature, enabling them to effortlessly upload their 360° videos for processing. Once uploaded, users are guided to define both the number and the duration of segments, as visually demonstrated in Fig. 2. Upon completing this step, users can proceed by clicking the "Upload" button to initiate the processing of their video content. Once educators have uploaded their videos, they will need to allow some time for the platform to process the data. During this processing period, educators can access their platform accounts and utilize the available YouTube functions, as shown in Fig. 3. It is important to note that user registration is not currently supported in our initial platform version, but it will be incorporated in future updates. However, in the meantime, educators can take advantage of the platform's integration with YouTube, enabling them to publish their 360° videos directly on the YouTube website. This seamless integration allows students to freely access and views the videos with ease, as depicted in Fig. 4.

B. Tool Evaluation: A Usability Testing

The primary objective of this study is to enhance the learning experience of students through the utilization of 360° immersive educational videos. To achieve this goal, we have developed a comprehensive prototype platform that empowers educators to seamlessly upload, edit, and publish their own 360° videos. One of the key advantages of our platform is its user-friendly interface, which eliminates the need for programming skills. This accessibility feature significantly reduces the time and effort required for educators to create their own educational VR content, allowing them to focus more on delivering impactful learning experiences to their students.



Is there any tool to assist in processing immersive 360° educational content?
Where can I host my 360° educational content?

TABLE I. THE EXPERIMENTS OF USABILITY TESTING

Participants' disciplines	Interview questions	Tasks
P1-information systems	Ease of use	Each professor was assigned a specific 360° video. They were required to upload, edit, and publish the video using our platform
P2-information systems	Ease and difficulty	
P3-Finance	Usefulness	
P4-Computer science and engineering	Suggestions	
P5-Geography	prior experience using or not using virtual reality	
P6-Communication	perceptions regarding the ease of generating VR content and integrating it into their teaching practice	

1) Evaluation participants: Nelson's (1993) recommended that as few as five users can effectively identify 85% of the usability issues associated with a particular technology [16]. Therefore, our study invited six full-time professors from a university located in the Midwest region of the United States to evaluate our high-fidelity prototype since our target users will be teachers. The participating professors represented diverse disciplines including information systems, computer science and engineering, finance, geography, and communication (see Table I). Prior to their participation, the study received approval from the Institutional Review Board (IRB), and the professors were invited to join the experiment after providing their informed consent by signing the consent form.

2) Evaluation tasks: To ensure the authenticity and naturalness of user interactions, the experiments were conducted in the participants' natural environments. This approach provided the advantage of observing the participants' natural process of interacting with our platform. The participants were initially instructed to perform various tasks using our platform, and their interactions were recorded using the Zoom share screen function. Following the task completion, the participants were then interviewed about their experiences, and these interviews were also recorded via Zoom. By conducting the experiments in this manner, we aimed to capture a comprehensive understanding of the participants' interactions and gather valuable insights from their firsthand experiences.

Prior to the experiment, each professor was assigned a specific 360° video and tasked with completing the upload, editing, and publishing tasks for that video using our platform (see Table I). The participants were required to go through each step of the platform, providing their insights and thought processes using the think-aloud method during the task execution. This approach allowed the investigator to gain a deeper understanding of how the participants performed the tasks and their decision-making processes.

Following the task completion, follow-up interviews were conducted with each participant. These interviews lasted approximately half an hour, during which the participants shared their experiences, thoughts, and feedback on the platform. Transcripts of the interviews were created to capture the details of the discussions.

The data collection process involved taking notes and recording videos of both the think-aloud sessions and the interviews. This comprehensive approach ensured that valuable information was captured and provided a rich dataset for further analysis and evaluation.

During the experiments, participants were prompted with think-aloud questions to elicit their thoughts and observations as they performed tasks on the platform. These questions included inquiries about their visual focus, the ease or difficulty of locating the next step, their understanding of video editing techniques, and any challenges encountered during the uploading process.

3) The interview sessions: Subsequent to the experiments, follow-up interviews were conducted to gather additional insights. The interview questions encompassed topics such as the participants' prior experience using virtual reality (VR) for teaching, their reasons for not utilizing VR if applicable, and their perceptions regarding the ease of generating VR content and integrating it into their teaching practice (see Table I).

In addition to these specific questions, we also incorporated usability-related inquiries aligned with Norman's usability goals. These goals emphasize the assessment of effectiveness, efficiency, learnability, memorability, error prevention, and user satisfaction. By addressing these usability dimensions, we aimed to gain a comprehensive understanding of the participants' experiences with our platform and identify areas for improvement. During the follow-up interviews, participants were asked a series of questions to assess their perception of the platform and its usability. Some of the key questions included (see Table I):

- Ease of use: Participants were asked to express their opinion on the ease or difficulty of using the platform to upload, edit, and publish the video. They were encouraged to provide reasoning for their response, highlighting specific features or aspects that contributed to their perception.

- Ease and difficulty: Participants were asked to identify the easiest and most challenging parts of the platform. This allowed them to pinpoint areas where they found the process intuitive and seamless, as well as areas that presented obstacles or required additional effort.

- Usefulness for teaching: Participants were queried about the usefulness of the platform for their teaching purposes. They were encouraged to elaborate on their response, discussing how the platform could enhance their teaching methods, engage students, or improve the learning experience.

- Suggestions for improvement: Participants were asked to provide feedback on areas of the platform that could be improved. This could include specific features, functionalities, or user interface elements that could enhance the user experience. Additionally, participants were invited to share their expectations for additional functions that they would like to see implemented in the platform.

By exploring these questions, we aimed to gather valuable insights from the participants to refine and enhance the platform, addressing their needs and preferences to create a more user-friendly and valuable tool for educational purposes.

4) Pilot study: To ensure the effectiveness of the tasks and interviews, a pilot test was conducted prior to the main study. The pilot test aimed to identify any confusing instructions or questions and to ensure the clarity and relevance of the provided information.

During the pilot test, a single participant was invited to complete the tasks and participate in an interview. The participant's feedback was valuable in identifying areas of confusion or ambiguity in the instructions and questions. Based on the participant's input, minor adjustments were made, such as reordering questions, rephrasing instructions, and removing redundant or similar questions.

It is important to note that the data collected from the pilot participant was not included in the final analysis since their participation was primarily intended to test the clarity and effectiveness of the instructions and questions, rather than to contribute valuable data to the study.

By conducting the pilot test and incorporating participant feedback, the study aimed to enhance the quality and reliability of the data collected from the main study, ensuring that the tasks and interviews provided meaningful and insightful information from the participants.

5) Data analysis: In this study, data were collected through multiple methods, including think-aloud Q&A, screen capture video analysis, and follow-up interviews. The collected data, including notes, videos, and interview transcripts, were analyzed using qualitative data analysis techniques.

The analysis process involved two main coding methods: open coding and axial coding. Open coding was initially conducted by the two researchers to identify preliminary concepts of interest. Printed documents, paper, markers, and a blackboard were used during discussions to facilitate the coding process. Due to the nature of the materials used, measuring inter-coder reliability was challenging.

After the open coding stage, axial coding was applied to identify and group themes in the data. The same two coders continued coding the data using this approach. The method of constant comparison was employed, wherein newly added transcripts were compared to previously identified concepts and categories that emerged throughout the analysis process (Corbin & Strauss, 2008; Merriam, 2009).

Throughout the analysis, the two researchers engaged in discussions to explore similarities and differences in the axial themes that emerged from the data. This iterative process allowed for a deeper understanding of the data and the development of meaningful interpretations.

By employing these qualitative data analysis methods, the study aimed to uncover insights and patterns within the collected data, facilitating a comprehensive understanding of the participants' experiences and perspectives related to the platform and its usage in education.

IV. I-TECH EVALUATION RESULTS

The designed platform was specifically created to provide professors from various disciplines with a user-friendly solution for uploading, editing, and publishing 360° videos to minimize their workload and technical challenges. To assess the effectiveness of the platform and gather feedback, a total of five professors from different disciplines were recruited as participants. These professors were invited to use the platform and subsequently interviewed to obtain their insights and opinions.

The analysis of the collected data focused on multiple perspectives, including task completion time and the occurrence of errors. By examining these factors, the study aimed to evaluate the platform's usability and efficiency in supporting professors with diverse backgrounds in utilizing 360° videos for educational purposes.

Through this analysis, the study sought to gain valuable insights into the platform's strengths and weaknesses, allowing for further improvements and refinements based on the feedback provided by the participating professors.

A. Task Time and Errors

The participants finished their tasks from three minutes to five minutes with an average of three minutes 25 seconds. All of them made no errors since they reported that the steps were simple and clear when they performed the tasks. However, three of them did have hesitations when trying to understand Step Three to segment the video into different chapters. After the investigator quickly asked them to view the example shown on the left of the page, they got the clue and finished the task without difficulties.

B. Themes from Think-aloud and Interviews

1) VR vs 360° videos: During the interviews, participants provided their perspectives on the differences between virtual reality (VR) design and 360° video when applied in their teaching scenarios. They unanimously expressed the belief that using 360° video for educational purposes is easier and more time-saving compared to VR design. Here are some of their responses:

Participant 1: "It is less complex. 3D programming needs lots of coding to do it. This one cuts the time for me to prepare for lessons."

Participant 2: "There is the use case (360° video). I worked with a camera. It was not that hard, just like put the camera on the tripod and shoot a video. This is very easy…I haven't worked with it (VR programming). But I think it involves some API. That study involves programming. So it's like a learning curve."

These statements highlight the participants' perception that working with 360° videos is less technically demanding and more accessible compared to VR design, which often involves programming and a steeper learning curve. They appreciate the simplicity and ease of use associated with capturing 360° videos using a camera, which allows them to focus more on the content creation and lesson preparation rather than technical intricacies.

The participants' consensus on the advantages of using 360° video suggests that it offers a convenient and efficient solution for incorporating immersive experiences into their teaching, saving time and reducing the complexity typically associated with VR design.

2) Ease of use: During the interviews, all participants expressed their unanimous agreement that the platform was easy to use, which aligns with one of the key usability goals of the project according to (Davis, 1989) [17]. Here are some of their responses:

Participant 3: "Just now, there were not a lot of things to do. From this perspective, I think it is easy...Every step is easy."

Participant 1: "I think it is quite easy and user-friendly to upload the video, and it is quite straightforward. The instruction is quite direct."

Participant 2: "It is easy. You just finish all the steps and then upload."

Participant 4: "It is not difficult. It is easy."

Participant 5: "It is easy to use."

Participant 6: "I think it's easy."

These responses indicate that all participants found the platform to be user-friendly and straightforward in its operations. They highlighted the ease of uploading videos and completing the required steps without encountering any significant challenges. The participants' overall consensus on the platform's ease of use validates the project's aim to create a user-friendly environment for educators to upload, edit, and publish 360° videos without facing technical complexities.

3) Usefulness: During the interviews, participants expressed their views on the usefulness of the platform for their current or future teaching. They recognized the potential value it could bring to their instructional practices. Here are some of their responses:

Participant 3: "I think it is a very good idea (to use this platform for her international business tours)."

Participant 1: "In the future, it might be quite useful for my courses. Students today like interaction, more visual attention to stay longer. It eliminates the explanation, and students could visualize it."

Participant 2: "It could be useful. It provides me with the way to upload and cut. So I do not have to worry about going to Youtube. I know (via) Youtube, or any platform, cutting it, you have to, the interface is just overwhelming. So I think this one is, the simpler, the better."

Participant 5: "Well, for my classes, I think it might be useful. Now I am thinking I can use it in the future."

These responses highlight the participants' recognition of the platform's potential usefulness in enhancing their teaching practices. They acknowledged the benefits of incorporating interactive and visually engaging content through 360° videos to improve student engagement and understanding. The convenience of uploading and editing videos directly on the platform was also highlighted as a significant advantage compared to other platforms that might have complex interfaces. Overall, the participants expressed positive attitudes toward the platform's usefulness, indicating their willingness to incorporate it into their teaching activities.

4) Integration of different functions: During the interviews, participants expressed their appreciation for the integrated functions of the platform, which alleviated the effort required to create 360° video classes. Here are some of their responses:

Participant 2: "I tried to use 360° video to teach before. So you have to go...Youtube allows some (to upload, edit, and publish), Facebook allows some others. There are some allowing photos, but you have to pay for videos. It is very confusing and useless... That's (the platform) easy and straightforward."

Participant 4: "In this platform, I do not need to learn some kind of new technology or combine different software together. Your platform provides all these required. This can reduce much time for customers."

These responses indicate that participants found the platform to be a comprehensive solution that eliminated the need to navigate multiple platforms or software tools to accomplish their desired tasks. The convenience and simplicity of having all the necessary functions integrated into one platform were highly appreciated. Participants highlighted the time-saving aspect of using the platform, as they no longer needed to spend excessive effort learning new technologies or managing various software tools. This further reinforced their positive perception of the platform's design and it’s potential to streamline their workflow in generating 360° video classes.

5) Expectations and improvements: During the interviews, participants shared their expectations for the future design of the platform, highlighting their needs in terms of feedback, display, and information accessibility. Here are some of their responses:

Participant 3: "Every step is so simple. I do not know how to improve."

Participant 1: "Overall, the platform is super easy for users. Maybe when you break down the video, you can immediately see which sections you can break down."

Participant 2: "The improvement is in the setting. For example, Step 1, like a big No. 1 to go next. A big number like the background. So you know where you are at in the process."

Participant 4: "To insert some part, for example, explanation voice or text function. If we have those that would be great."

These responses indicate that while participants found the current design of the platform to be easy and useful, they also expressed their desires for further enhancements. Participants highlighted the importance of clear visual cues and indicators, such as prominent numbers or markers, to provide a better understanding of the current step in the process. Additionally, they expressed a need for additional features like the ability to insert explanatory voiceovers or text, which would enhance the educational experience for both educators and students.

In summary, the design of our platform successfully provides educators with an easy-to-use and integrated solution that fulfills their basic needs for immersive educational videos. Through usability testing and participant feedback, we have confirmed that the platform is capable of assisting educators in achieving their educational goals. The participants' suggestions for future improvements provide valuable insights for enhancing the platform's functionality and usability even further.

V. Discussion and Future Work

Despite the increasing popularity of 360° videos and the potential they hold for enhancing educational experiences, there are certain limitations associated with the tools available for teachers to develop these videos and publish them. It is important to acknowledge these limitations in order to understand the current state of the technology and the areas that need further improvement.

One of the limitations lies in the complexity and accessibility of the tools used to create 360 videos. While there are software applications and platforms available that facilitate the creation process, they often require a certain level of technical expertise and can be daunting for educators without a background in video production or immersive technologies. Additionally, the cost of specialized equipment, such as multi-camera rigs or high-end cameras, can pose a barrier for schools and educators with limited resources.

It is important to highlight the significant advancements made in immersive technologies by devices such as the Facebook Quest 2 [18] and the Apple Vision Pro [19] Gear. The Facebook Quest 2 has gained popularity as an accessible and affordable virtual reality (VR) headset. It allows users to easily experience 360° videos and other VR content without the need for external sensors or a high-powered computer, thanks to its wireless and standalone design. On the other hand, the Apple Vision Pro Gear, although not yet released, is anticipated to be a device merging both virtual reality and augmented reality (AR) capabilities. By overlaying virtual objects onto the real world, it creates a mixed reality experience, enabling users to interact with digital content in their environment. These advancements in hardware technology are proving to be valuable for educators and students, as they make immersive experiences more readily accessible for educational purposes.

The metaverse [20] is a term used to describe a collective virtual shared space where people can interact with each other and digital content in real time. It combines elements of the physical and virtual worlds, creating an immersive and interconnected environment. In the metaverse, individuals can engage in various activities, such as socializing, working, learning, and exploring, using virtual reality (VR), augmented reality (AR), and other immersive technologies.

The concept of the metaverse has gained significant attention in recent years, fueled by advancements in technology and the growing popularity of VR and AR experiences. It represents a vision of a fully realized digital realm where individuals can transcend physical limitations and immerse themselves in limitless virtual experiences.

In the field of education, the metaverse holds great promise for transforming the way students learn and engage with educational content. By creating immersive and interactive virtual environments, the metaverse can offer new possibilities for experiential learning, simulation-based training, and collaborative problem-solving and global connections.

However, the full realization of the metaverse in education is still in its early stages. Technical challenges, such as creating seamless interoperability between different platforms and devices, ensuring data privacy and security, and developing user-friendly interfaces, need to be addressed. Furthermore, ethical considerations related to virtual experiences and the potential for exacerbating existing social inequalities should be carefully navigated.

Our current work aims to provide educators with a high-fidelity prototype that allows them to easily upload, edit, and publish their 360 videos for their immersive classes instead of using different sources to edit their videos and then find places to publish their videos, which brings lots of challenges to them. Our next step is to refine the prototype and make mature market-oriented software so that all educators can use it.

VI. Conclusions

In this paper, we introduce i-Tech, a novel tool designed to support educators in the creation and publication of their 360 video content. i-Tech offers a user-friendly and intuitive interface that empowers educators to leverage the immersive capabilities of 360 videos for educational purposes. Our main objective was to provide educators with practical solutions for easily uploading, editing, and publishing 360° videos to enhance the immersive learning experience of students. By utilizing video observation, think-aloud protocols, and interviews, we successfully integrated the necessary functionalities into our platform, enabling educators to create 360 class videos efficiently. While the availability of integrated 360° video platforms for educators is currently limited, the positive outcomes of our study offer valuable insights for future research in this field. The implications of our design can extend beyond educators and be applied to other user groups seeking to create 360° videos for various purposes.

However, it is important to acknowledge the limitations of our study. We conducted usability testing with a relatively small sample of seven professors from different disciplines. Despite the modest sample size, it aligns with Nelson's suggestion that even a small number of users can effectively identify a significant portion of usability issues in a technology. Additionally, our platform is currently in its initial version, focusing primarily on streamlining the process of cutting, uploading, and publishing 360° videos for educators.

In future studies, we plan to enhance the functionality of our platform to minimize technical challenges and provide a user-friendly experience for educators and other users. We believe that our study has made a valuable contribution to the understanding of integrated 360° video design, considering the limited existing research in this area. Our hope is that our findings will inspire designers and researchers to further explore this topic, leading to the development of innovative designs and applications that can benefit a broader range of users.

Acknowledgment

We would like to extend our sincere appreciation to Kecheng Tao for his invaluable support in programming the tool presented in this work. His expertise and dedication were instrumental in developing and fine-tuning the functionalities of the tool, making it an integral part of our re-search project.

Institutional Review Board Statement

The authors of this research study obtained the necessary approvals and/or waivers from the Institutional Review Board (IRB) at St Cloud State University for the project. The study was conducted in accordance with the ethical guidelines and regulations set forth by the IRB. Necessary measures were taken to ensure the protection of participants' rights, privacy, and confidentiality throughout the research process.

A Lightweight Neural Network for Accurate Rice Panicle Detection and Counting in Field Conditions

Wenchao Xu[1], Yangxu Wang[2]

School of Electrical and Computer Engineering, Nanfang College Guangzhou, Conghua 510970, China[1]
Department of Network Technology, Software Engineering Institute of Guangzhou, Conghua 510990, China[2]

***Abstract*—Monitoring rice spikelet yield is crucial for ensuring food security, but manual observations are tedious and subjective. Deep learning approaches for automated counting often require high device resources, limiting their applicability on low-cost edge devices. This paper presents the Rice Lightweight Feature Detection Network (RLFDNet). RLFDNet designed for the field of computer vision, features a lightweight encoder and decoder, effectively decoding shallow and deep information within its neural network architecture. Innovative designs including dense feature pyramid network, reinforcement learning guidance, attention mechanisms, dynamic receptive field adjustment, and shape feature fusion enable outstanding performance in object detection and counting, even with low-resolution images. Across different elevations, ranging from 7m to 20m, RLFDNet demonstrates significantly superior accuracy and inference efficiency compared to other advanced object detection methods. With a parameter count of only 4.40 million, it achieves an impressive frame rate of 80.43 FPS on a GTX1080Ti GPU, meeting real-time application requirements on inexpensive devices. RLFDNet's exceptional performance is further highlighted by an MAE of 1.86 and an R² of 0.9461, along with an average precision of mAP@0.5 reaching 0.91. These results underscore RLFDNet's capability as a potent and reliable visual tool for agricultural practitioners, offering promising prospects for future research endeavors.**

Keywords*—Computer vision; deep learning; lightweight; neural network architecture; remote sensing

I. INTRODUCTION

Rice is a pivotal global crop, essential for food security, particularly for almost half of the world's population. Metrics like spikes per square meter and grain size profoundly influence cereal crop yield [1] [2]. However, accurately counting rice spikes encounters challenges due to outdoor environment complexities, including size variations, lighting conditions, and occlusion. Traditional monitoring methods hinge on manual observation [3], which is time-consuming and subjective, impacting rice quality and yield.

In recent decades, the rapid development of computer vision has made deep learning (DL) a key research field in artificial intelligence [4]. Similarly, deep learning has also been widely applied in agriculture, particularly in various agricultural information management practices [5] [6]. Many studies utilize machine learning for crop yield prediction by estimating the quantity of fruits, such as cotton [7], citrus fruits [8], sugar beets [9], and rice. In the realm of rice, various studies have been conducted: Xiong et al. [10] proposed a rice spike segmentation algorithm based on superpixel region generation, CNN, and superpixel optimization. This method effectively segments and recognizes complex rice spikes, but may involve unreasonable assumptions, such as simplification of rice spike shapes. Misra et al. [11] introduced SpikeSegNet for rice spike detection and counting, achieving an average accuracy of 95%. However, it overly relies on lighting conditions. Wang et al. [12] presented an algorithm utilizing three-dimensional point clouds for crop size estimation, particularly suited for spike counting in high-density scenarios, yet highly relies on high-quality sensor data. Shu et al. [13] proposed a rice spike detection method based on the SSD algorithm, with an average precision mAP of 38.1%. The model's accuracy still needs improvement.

Computer vision applications in agriculture, particularly in rice spike detection, have demonstrated significant potential. However, these models encounter critical issues such as low detection accuracy or lack of lightweight design, resulting in suboptimal user experiences and high entry barriers. Furthermore, due to variations in terrestrial environments, these methods are susceptible to significant errors.

Recognizing these challenges, researchers have turned to micro unmanned aerial vehicles (UAVs). Micro UAVs offer several advantages, including convenient platform setup, low operating and maintenance costs, small size, light weight, simple operation, high flexibility, and short operation cycles, making them an ideal choice for agricultural applications. Tri et al. [14] combined drones with deep learning to predict paddy field yields, marking the first use of drones for image collection and deep learning-based rice spike classification. Hayat et al. [15] proposed an unsupervised Bayesian learning-based segmentation algorithm for rice spike segments, achieving an average F1-score of 82.10%. However, they require significant computational resources and may not be suitable for real-time applications in resource-constrained environments. Reza et al. [16] introduced a method for rice yield estimation based on K-means clustering and segmentation of low-altitude UAV images. However, their method exhibits relatively low accuracy, with a relative error ranging from 6% to 33%, making it challenging to meet the requirements for automated detection of rice spike yield. In summary, further improving accuracy and efficiency is a natural and important research direction.

To address this challenge, the focus of this study is on achieving high accuracy and lightweight design in the model architecture, taking into account the deployment requirements of edge devices in the field of plant science. The proposed method for rice spike localization and counting is a deep learning-based approach named the Rice Lightweight Feature Detection Network (RLFDNet). RLFDNet utilizes the lightweight backbone CSPDarknet [17] and further incorporates a concise and efficient encoder-decoder module to decode features from both shallow and deep layers. Unlike existing methods, RLFDNet primarily aims to overcome the recognition challenges posed by small and dense targets. It offers several advantages: Firstly, it emphasizes higher spatial resolution to retain detailed information at each pixel position. Secondly, it focuses on extracting more discriminative high-level semantic information. Specifically, the model decoder maximizes the utilization of depth-encoded feature layers generated by the encoder to capture abstract information. By employing an adaptive strategy, RLFDNet effectively restores spatial resolution and merges feature layers from non-adjacent levels. Additionally, a channel attention mechanism is introduced to suppress irrelevant pixel information at critical positions, thus alleviating the difficulty of feature extraction in dense scenes. RLFDNet achieves a balance between accuracy and computational efficiency, making it suitable for real-world implementation on resource-constrained devices, unlike existing methods that often prioritize accuracy over computational efficiency.

To validate the universality of the model design, this study utilized the Diverse Rice Panicle Detection (DRPD) dataset [18], which was publicly released by Teng et al. [19]. It is noteworthy that this dataset comprises field rice spikes captured by micro UAVs at different altitudes (7m, 12m, and 20m) and subsequently cropped. Undoubtedly, varying the altitude during capture results in different target sizes and densities of rice spikes in the images, posing a significant challenge for object detection models. Fortunately, extensive experimental results demonstrate that RLFDNet's accuracy and inference efficiency are significantly superior to other advanced object detection methods, showcasing better robustness and adaptability. RLFDNet's parameter count is only 4.40 million, and it reports an outstanding frame rate of 80.43 FPS on the affordable GTX1080Ti GPU, making it sufficient for real-time applications when deployed on inexpensive devices. The efficiency comparison is illustrated in Fig. 1.

In summary, this study makes three main contributions:

- Innovatively introduces a more precise encoder-decoder module and cleverly designs an efficient neural network structure, significantly enhancing the integration capability of image features and effectively improving feature extraction performance.

- Proposes the lightweight RLFDNet model specifically designed for the localization and counting of field rice spikes. Its lightweight architecture allows for flexible deployment on low-end edge devices, providing a novel solution for automated monitoring of rice spikes.

- Through comprehensive comparisons with mainstream object detection models, demonstrates the outstanding performance of the RLFDNet model on rice spike datasets of different scales compared to state-of-the-art methods, highlighting its significant advantages in object detection tasks.

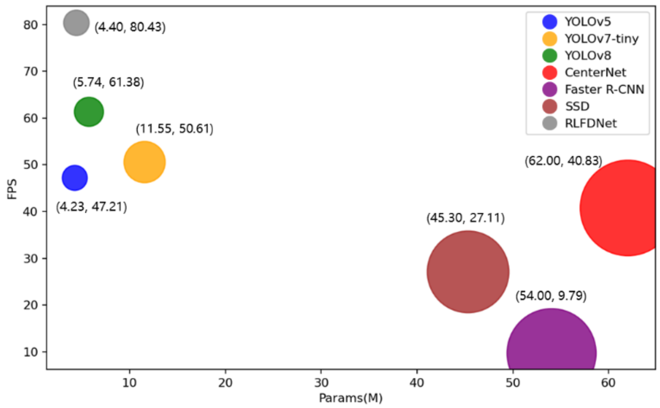

Fig. 1. Efficiency comparison of different models. Performed on a device with NVIDIA GTX1080Ti GPU (8G).

The layout of this paper is as follows:

In Section I (this section), the research background is introduced, and the problem statement is emphasized. Section II provides a detailed introduction and description of the proposed RLFDNet model. Section III conducts experiments and performs comprehensive comparative analyses with other models across various dimensions. Section IV delves into the factors influencing RLFDNet's performance and summarizes the model's innovative aspects. Section V concludes the study and outlines future research directions.

II. Materials and Methods

A. Datasets

This study is based on the publicly available dataset Diverse Rice Panicle Detection (DRPD) [19]. Aerial images of rice fields were captured at three different altitudes: GSD7m, GSD12m, and GSD20m. The images were cropped from the original aerial images, with each image having a size of 512×512 pixels. In total, 5,372 RGB sub-images were collected, annotated with 259,498 rice spikes exhibiting various morphological features. Details of the dataset are presented in Table I, where "Panicles per sub-image" indicates the number of spikes in each sub-image. The dataset includes four key growth stages: heading (1,903 sub-images), flowering (1,676 sub-images), early grain filling (1,235 sub-images), and middle grain filling (558 sub-images). It is noteworthy that, due to cropping by researchers and the high density of the aerial images, the difficulty varies across different altitudes. Rice spikes are larger and less dense at an altitude of 7m, presenting the lowest difficulty. In contrast, at an altitude of 20m, rice spikes are smaller, more densely distributed, and pose the greatest challenge. This requires the model to overcome challenges associated with low-resolution images and dense predictions. Additionally, factors such as different sizes, shapes, postures, occlusions, lighting conditions, and water reflections severely impact detection results. It is precisely because of these challenges that various methods were employed in the model design, carefully addressing these limitations to ensure the model's robustness and good overcome generalization performance. In this study, these challenges were successfully, leading to satisfactory experimental results, as demonstrated in the following sections.

TABLE I. DATASET DETAILS

GSD	Images	Labels	Panicles per sub-image
GSD_{7m}	3,810	106,878	27-30
GSD_{12m}	1,004	71,404	65-70
GSD_{20m}	558	81,216	140-150

B. Model Architecture

Taking into account the deployment requirements of edge devices in the field of plant science, the model architecture was designed with a focus on lightweight design. Effective design modifications were applied to the detection network structure, making it more comprehensive and detailed, particularly suitable for detecting rice spikes of varying sizes in the images. As shown in Fig. 2, the global architecture of the model consists of three main components: the Encoder for generating feature maps, the Decoder for feature parsing, and the Detector for visual output. The following sections will provide a detailed explanation of the design details and the rationale behind them.

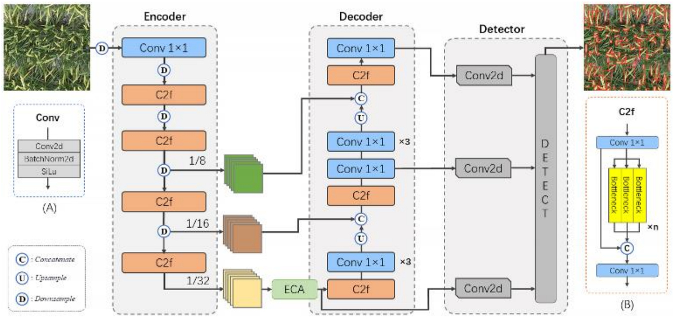

Fig. 2. The global architecture of the RLFDNet model.

1) Encoder: The role of the encoder is to map the input RGB image to feature maps. Given an input image $I \in R^{H \times W \times 3}$, RLFDNet employs the lightweight network CSPDarkNet [17] as the backbone for feature extraction. Down-sampling operations are performed using 2D convolution layers with a 3×3 kernel size and a stride of 2. CSPLayer [20] is inserted at different stages for feature extraction, combined with the C2f module [21] to generate feature maps at different stages. Through these operations, the input image undergoes 32 times downsampling, resulting in feature maps with channel numbers of 64, 128, and 256, representing 1/8, 1/16, and 1/32 of the original image, respectively. These feature maps carry richer gradient information and are utilized in the decoder.

In the final stage of the encoder, the Efficient Channel Attention (ECA) mechanism is applied. It compresses spatial information through global average pooling, learns channel attention information through a 1×1 convolution layer, and combines the channel attention information with the original input feature map. This approach avoids dimension reduction, effectively captures cross-channel interactions, and requires only a small number of parameters for excellent results. In summary, this encoder contributes to improving object detection performance, particularly in the extraction of features when dealing with targets of different scales.

2) Decoder: The role of the decoder is to combine and decode the features from the encoder, mapping them to the final output of object detection. In RLFDNet, after obtaining the feature layer output from the ECA attention mechanism, the C2f module is introduced to reduce redundant representations of convolutional kernels, significantly reducing the number of convolutions and parameters. At this point, this layer's features are passed as a branch to the Detector because it can maintain the detection of smaller objects. To better obtain high-level features and increase semantic information while considering model lightweighting, nearest neighbor upsampling is applied to the upper-level features, doubling the size of the feature map. The Conv layer receives features from the previous layer and concatenates three 1×1 convolutional layers, increasing the model's receptive field to cover a larger area of the image. Then, the corresponding scale-sized feature map extracted from the Encoder is concatenated, followed by another C2f and a 1×1 standard convolutional layer to reduce the number of parameters and computations. This portion of features is then split into two branches: one continues to concatenate the decoder for the same operations, and the other is output to the Detector for detection preparation. This design ultimately accumulates three sets of features at different scales, utilizing feature mappings of different scales for predictions, enhancing RLFDNet's perception of objects of different sizes.

3) Detector: The different-stage feature maps output from the Decoder are passed to the Detector. The main task of the Detector is to merge these feature maps and fuse the encoded information into the original feature map. It predicts the distances between each anchor point and the four edges of the target bounding box through the regression branch, determining the target's position. The Non-Maximum Suppression (NMS) is then applied to filter the generated prediction boxes. The Intersection over Union (IoU) evaluation metric is used to measure the overlap between two prediction boxes. By comparing the IoU values between prediction boxes, the model determines whether they belong to the same object, ultimately eliminating redundant detection results.

Overall, the RLFDNet model has a concise overall architecture design. Through the implementation of multi-scale feature fusion, context information aggregation, and the introduction of channel attention mechanisms, the model's perception and expressive capabilities are enhanced. This enables the model to better adapt to the detection of objects of different sizes and complexities. With minimal parameter settings, the model maintains its lightweight nature, reducing memory requirements, making it easy to deploy on low-end edge devices, and ensuring good real-time performance.

C. Loss Function

The loss function, serving as a guide for adjusting weights during backpropagation, measures the error between the forward propagation results of a neural network and the ground truth values in each iteration. In the implementation of

RLFDNet, various commonly used loss functions were explored. For the Complete Intersection over Union (CIoU) loss function [22], which functions as the bounding box loss, the calculation method is as described in Eq. (1) and Eq. (2):

$$CIoU = IoU - \frac{\rho^2\left(b, b^{g^t}\right)}{c^2} - \alpha v \quad (1)$$

$$L_{CIoU} = 1 - CIoU \quad (2)$$

IoU represents the intersection ratio of the real bounding box and the bounding box. c denotes the minimum diagonal length of the bounding box enclosing the predicted box and the ground truth box, and $\rho^2\left(b, b^{g^t}\right)$ represents the Euclidean distance between the center points of the ground truth box and the predicted box. The calculation method of α and v is shown in Eq. (3) and Eq. (4):

$$v = \frac{4}{\pi^2}\left(arctan\frac{w^{g^t}}{h^{g^t}} - arctan\frac{w}{h}\right)^2 \quad (3)$$

$$\alpha = \frac{v}{(1 - IoU) + v} \quad (4)$$

In Eq. (3), h^{g^t} and w^{g^t} represent the height and width of the ground truth box; h and w represent the height and width of the prediction box. CIoU Loss function considers the coverage area, aspect ratio, and center distance, comprehensively, which can measure its relative position well, and solve the problem of optimizing the horizontal and vertical directions of the prediction box, but this method does not consider the direction matching between the target box and the prediction box, which leads to a slow convergence speed. Thus, this paper used the Smooth Intersection over Union (SIoU) loss function [23]. SIoU introduces the optimization of the vector angle between the target box and the predicted box and plays a significant role in the strawberry detection network through a linear combination of four components: angle cost, distance cost, shape cost, and IoU cost. Its calculation method is as described in Eq. (5) and Eq. (6):

$$L_{SIoU} = 1 - IoU + \frac{\Delta + \Omega}{2} \quad (5)$$

$$IoU = \frac{\left|B \cap B^{GT}\right|}{\left|B \cup B^{GT}\right|} \quad (6)$$

where B and B^{GT} represent a prediction box and a ground truth box, Ω represents the shape cost, Δ represents the angle cost, and the distance cost is redefined. Ω and Δ are defined in Eq. (7) and Eq. (8):

$$\Omega = \sum_{t=w,h}(1 - e^{-w_t})^{\theta} \quad (7)$$

$$\Delta = \sum_{t=x,y}(1 - e^{-\gamma\rho_t}) \quad (8)$$

In Eq. (7), $w_w = \frac{\left|w-w^{g^t}\right|}{max\left(w,w^{g^t}\right)}$, $w_h = \frac{\left|h-h^{g^t}\right|}{max\left(h,h^{g^t}\right)}$, θ indicates the degree of concern for Ω.

In Eq. (8), $\rho_x = \left(\frac{\left|b_{c_x}^{g^t} - b_{c_x}\right|}{c_w}\right)^2$, $\rho_y = \left(\frac{\left|b_{c_y}^{g^t} - b_{c_y}\right|}{c_h}\right)^2$, γ is defined in Eq. (9):

$$\gamma = 1 + 2\sin^2\left(arcsin\frac{max(b_{c_y}^{g^t}, b_{c_y}) - min(b_{c_y}^{g^t}, b_{c_y})}{\sqrt{(b_{c_x}^{g^t} - b_{c_x})^2 + (b_{c_y}^{g^t} - b_{c_y})^2}} - \frac{\pi}{4}\right) (9)$$

In Eq. (9), $b_{c_x}^{g^t}$ and $b_{c_y}^{g^t}$ represent the coordinates of the ground truth bounding box's center. b_{c_x} and b_{c_y} represent the coordinates of the predicted bounding box's center.

The SIoU loss function redefines distance loss by considering vector angles between required regressions, reducing regression freedom, accelerating network convergence, and enhancing accuracy. For instance, in densely packed rice panicles, SIoU effectively distinguishes boundaries, improving detection accuracy and stability. Therefore, SIoU is advantageous for detecting dense or small targets.

III. Experiments

A. Experimental Details

In this study, rice spike images captured at different altitudes, including 7m, 12m, and 20m, were used to evaluate the RLFDNet model. The detailed dataset information is shown in Table I, and images at each altitude were randomly divided into training, validation, and test sets in a ratio of 6:1:3. The experiments were implemented using the PyTorch deep learning framework [24] and accelerated with CUDA. Since each image's size was 512×512 pixels, inputting the model with the original image size maintained a low resolution, aligning more with the requirements of edge devices. To ensure the objectivity of results, all methods were trained and tested under the same configuration. During training, the batch size was set to 16, the learning rate was initialized to 0.01, Stochastic Gradient Descent (SGD) optimizer was used with a momentum factor of 0.937, and weight decay was set to 5×10^{-4}. To prevent overfitting and enhance model robustness, data augmentation techniques were applied, including color distortion, random translation, random flipping, random scaling, and random cropping. After configuring the relevant parameters, the RLFDNet model was optimized for 300 epochs based on convergence speed considerations.

B. Evaluation Metrics

When establishing a detection model, both precision and recall need to be considered. Therefore, this study used metrics such as Precision, Recall, F1-score, mAP@0.5, and mAP@0.5:0.95 to assess the model's performance and evaluate the detection results. The calculation methods for Precision, Recall, and F1-score are given by Eq. (10) to Eq. (12):

$$\mathrm{P} = \frac{TP}{TP+FP} \quad (10)$$

$$\mathrm{R} = \frac{TP}{TP+FN} \quad (11)$$

$$F1 = 2 \times \frac{P \times R}{P + R} \quad (12)$$

where, P represents precision, R represents recall, and F1 represents F1-score. TP (True Positive) denotes the number of positive samples correctly classified, TN (True Negative) represents the number of negative samples correctly classified. FP (False Positive) indicates the number of negative samples incorrectly classified as positive, while FN (False Negative) represents the number of positive samples incorrectly classified as negative.

The mean Average Precision (mAP) represents the overall performance at different IoU thresholds, including mAP@0.5 and mAP@0.5:0.95. Here, mAP@0.5 denotes the average mAP at an IoU threshold of 0.5, with a higher value indicating higher detection accuracy for that category. mAP@0.5:0.95 represents the average mAP across different IoU thresholds (ranging from 0.5 to 0.95 with a step size of 0.05), providing a more stringent evaluation of the model's performance. The calculation method for mAP is given by Eq. (13):

$$mAP = \frac{1}{n}\sum_{1}^{n} P(R)d(R) \qquad (13)$$

where, n is the number of classes, in this experiment, there is only one class, which is rice spikes, so n=1. In addition, since the distribution of rice spikes is dense, evaluating counting performance is also meaningful. Here, three metrics are used to assess the consistency between predicted and true values, including Mean Absolute Error (MAE), Root Mean Squared Error (RMSE), and Coefficient of Determination (R^2). Specifically, they are defined by the following Eq. (14) to Eq. (16):

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|\widehat{y_i} - y_i| \qquad (14)$$

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(\widehat{y_i} - y_i)}^{2} \qquad (15)$$

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(\widehat{y_i} - y_i)^2}{\sum_{i=1}^{n}(\overline{y_i} - y_i)^2} \qquad (16)$$

where, n is the number of samples, y_i is the true count, $\widehat{y_i}$ is the predicted count, and $\overline{y_i}$ is the mean of the true counts. These metrics provide a quantitative assessment of the model's ability to accurately predict the count of rice spikes. The result of R^2 falls within the range [0, 1], indicating the proportion of the variance in the predicted values to the variance in the actual values near the mean. This metric can be interpreted as the goodness of fit of the model, where 1 represents a perfect fit, and 0 indicates no linear relationship between the actual counts and the predicted values.

C. *Analysis of Counting Performance of RLFDNet*

To comprehensively evaluate the performance of the RLFDNet model across different altitudes (7m, 12m, and 20m), the model was trained and tested on each dataset, and the experimental results are presented in Table II.

Furthermore, Fig. 3 illustrates a linear regression plot, which is an indispensable tool in the analysis of counting task experiments. It visually presents the counting performance differences between RLFDNet model inference and manual counting. A closer alignment of points to the perfect prediction line indicates better model fitting. The results show that the model performs exceptionally well at 7m altitude, demonstrating more accurate predictions and higher model fitting (R^2=0.9461). Conversely, at altitudes of 12m and 20m, the model's performance slightly decreases, showing larger MAE, RMSE, and slightly lower R^2, indicating potential challenges in predicting at these two altitudes.

A deeper investigation into the performance differences at different shooting heights and discussion of the possible reasons for these differences were conducted. The variations in this regard are mainly influenced by two key factors: shooting height and environmental conditions. Firstly, changes in shooting height directly affect the size and resolution of panicles in the images. At lower altitudes, panicles are relatively larger and easier for the model to capture details. At higher altitudes, smaller panicles increase the difficulty of detection. Secondly, lighting conditions also vary at different altitudes, leading to varying degrees of light and shadow in the images. Uniform lighting at lower altitudes facilitates the model in capturing the edges and details of panicles. Conversely, lighting conditions at higher altitudes may be more complex, adding to the difficulty of model inference.

At the same time, Fig. 4 illustrates images with the highest prediction errors in each dataset. Ground Truth (GT) is represented by red points in the images, indicating manual counting results, while Predicted (PD) is indicated by red boxes in the inference images, representing the model's inference results. This aids in understanding the potential reasons behind these inaccuracies. Clearly, these images confirm a common notion that they mostly contain significant environmental noise. Factors such as differences in lighting, small target sizes, and high density significantly increase the difficulty of detection. In some cases, even experienced human experts may find identifying spikes challenging. A comprehensive evaluation of counting performance across the entire dataset will be further discussed in the next section.

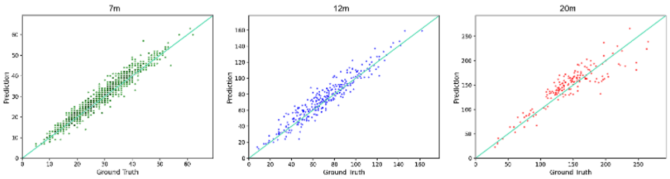

Fig. 3. The linear regression graph, illustrating the variance between counting results of RLFDNet model and human counting.

TABLE II. RLFDNET'S COMPREHENSIVE PERFORMANCE ACROSS ALTITUDES

GSD	P	R	mAP@0.5	mAP@0.5:0.95	MAE	RMSE	R^2
GSD_{7m}	0.915	0.923	0.961	0.691	1.86	2.49	0.946
GSD_{12m}	0.830	0.813	0.861	0.423	6.97	9.07	0.906
GSD_{20m}	0.871	0.839	0.907	0.614	15.26	19.29	0.816

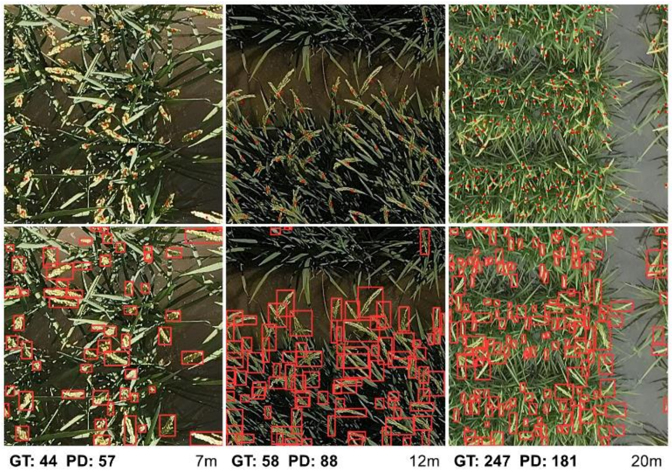

Fig. 4. Images with the maximum errors at each altitude. (GT: Red points - manual counting results; PD: Red boxes - RLFDNet's inference results).

D. Comparison with different Object Detection Method

To compare the superiority of the RLFDNet model, six advanced and commonly used object detection models, including YOLOv5 [25], YOLOv7-tiny [26], YOLOv8 [21], CenterNet [27], Faster R-CNN [28], and SSD [29], were selected for a comprehensive analysis of evaluation performance, counting performance, and model lightweighting. To ensure fair and objective results, they were trained and tested on identical training, validation, and test sets for each altitude dataset. Although this effort was substantial, it was meaningful, providing insights into the differences between different models and presenting results more objectively.

1) Performance comparison: The results of the evaluation performance for different models are presented in Table III. Upon examination of the test results, RLFDNet demonstrated satisfactory counting performance. While YOLOv8's results were very close, even surpassing RLFDNet in one metric at altitudes 12m and 20m, the difference was marginal. Overall, RLFDNet outperformed its counterparts. Conversely, other models exhibited slightly inferior performance in detecting rice panicles at each altitude, particularly Faster R-CNN and SSD. This suggests that these models may lack robustness when dealing with smaller targets or more complex conditions, hindering their ability to achieve highly accurate object detection.

2) Counting performance comparison: Furthermore, a detailed analysis of counting performance was conducted for each altitude dataset, and the experimental results are presented in Table IV. Observations revealed that YOLOv8, CenterNet, and RLFDNet consistently demonstrated stable prediction performance at each altitude, with RLFDNet maintaining the optimal performance. On the other hand, Faster R-CNN and SSD exhibited higher errors and lower fitting accuracy at higher altitudes, corroborating the results of the performance evaluation. These models faced challenges in object detection when dealing with smaller targets or more complex environments. In contrast, RLFDNet maintained relatively good and stable performance even at higher altitudes with smaller targets and higher density. The experiments indicate that RLFDNet exhibits strong generalization and robustness in counting performance.

TABLE III. COMPARISON OF EVALUATION PERFORMANCE ACROSS DIFFERENT MODELS

GSD	Model	F1	mAP@0.5	mAP@0.5:0.95
GSD$_{7m}$	YOLOv5	0.835	0.884	0.528
	YOLOv7-tiny	0.870	0.923	0.609
	YOLOv8	0.919	0.959	0.675
	CenterNet	0.600	0.958	0.756
	Faster R-CNN	0.647	0.654	0.635
	SSD	0.478	0.513	0.463
	RLFDNet	0.942	0.961	0.691
GSD$_{12m}$	YOLOv5	0.818	0.956	0.409
	YOLOv7-tiny	0.554	0.674	0.397
	YOLOv8	0.819	0.860	0.428
	CenterNet	0.638	0.793	0.432
	Faster R-CNN	0.493	0.392	0.364

	YOLOv8	10.00	12.80	0.873
	CenterNet	9.61	12.12	0.883
	Faster R-CNN	18.51	21.55	0.653
	SSD	28.66	32.87	0.660
	RLFDNet	6.97	9.07	0.906
GSD$_{20m}$	YOLOv5	15.76	23.60	0.816
	YOLOv7-tiny	23.31	29.65	0.549
	YOLOv8	15.34	21.85	0.812
	CenterNet	19.72	24.91	0.696
	Faster R-CNN	27.34	35.57	0.302
	SSD	33.81	42.16	0.195
	RLFDNet	15.26	19.29	0.816

3) Model lightweight comparison: After evaluating model performance metrics and counting performance, it is crucial to consider another key factor in the design of the RLFDNet model – achieving lightweightness. To assess different models, the number of parameters (Params) is used to reflect the total trainable parameters in the network, indicating model complexity and its capacity to learn and represent features. The calculation is defined by Eq. (17):

$$Params = [i \cdot (k \cdot k) \cdot o] + o \qquad (17)$$

where, i is the input size, k is the convolution kernel size, and o is the output size. Regarding inference efficiency, the evaluation is conducted using the Frames per Second (FPS) metric to reflect the model's inference speed. A higher FPS indicates a faster generation of inference results. The calculation is defined by Eq. (18):

$$FPS = \frac{1000}{pre{-}process + inference + NMS} \qquad (18)$$

Here, pre-process, inference, NMS is pre-processing, inference, and Non-Maximum Suppression time, respectively for each image.

In this experiment, RLFDNet's efficiency is compared with different models. FPS measures the number of image frames the model can process per unit time, while Params is a direct measure of model complexity and an important constraint for deployment. The tests were conducted on an NVIDIA GTX1080Ti GPU (8G) device, a lower-end GPU with slower computational speed. The results are shown in Fig. 1. It is evident that RLFDNet achieves an excellent overall performance. Compared to YOLOv5, which is relatively close in performance, RLFDNet has only 4% more Params, while the FPS has increased by 70%, reaching 80.43 frames per second. This improvement is significant, as it maintains a relatively small total parameter count while substantially enhancing inference efficiency. It contributes greatly to deploying the model on low-end edge devices. The size of the model's parameter count directly impacts whether individuals with budget-friendly devices can enjoy the benefits of advanced technology, especially in resource-constrained fields such as agriculture, where edge devices, embedded systems, and mobile robots provide practitioners with more decision support and production management tools.

IV. Discussion

This study introduces the RLFDNet model, offering a lightweight and real-time method for rice panicle localization and counting. The model leverages the lightweight backbone CSPDarknet and introduces an innovative strategy in the design, maintaining a relatively low image resolution in experiments to meet the requirements of edge devices, achieving high accuracy and lightweight characteristics. As shown in Fig. 5, the model accurately localizes and counts rice panicles in four crucial growth stages at different shooting heights of 7m, 12m, and 20m. Moreover, RLFDNet demonstrates good robustness and adaptability when facing common natural factors in the field, such as strong sunlight, overcast conditions, and interferences like mutual occlusion, varied panicle poses, changes in lighting conditions, and water reflections, as depicted in Fig. 6.

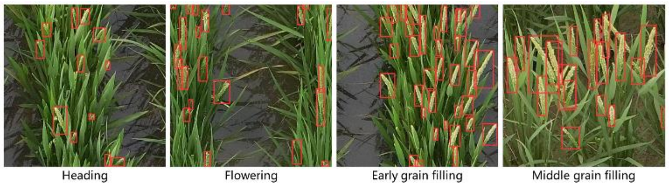

Fig. 5. Rice panicle detection results at four different growth stages (Example at 7m altitude).

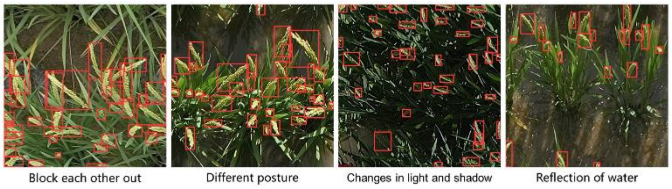

Fig. 6. Detection results of rice panicles in the face of various influencing factors (Example at 7m altitude).

In summary, RLFDNet's design incorporates several key innovations:

1) Multi-Scale receptive fields and feature fusion: RLFDNet employs a pyramid network architecture in the encoder to capture multi-scale information effectively. Different convolutional layers' receptive fields help in understanding spatial object relationships, while a feature fusion mechanism integrates features from various scales to enhance dense target detection.

2) Reinforcement learning-guided object detection: RLFDNet dynamically adjusts its object detection strategy during training using reinforcement learning mechanisms. This adaptive approach helps the model better adapt to changes in altitudes and environmental conditions, enhancing performance in complex scenes.

3) Attention mechanism integration: RLFDNet incorporates attention mechanisms at the connections between the encoder and decoder, allowing the model to adaptively focus on important regions in the image. By introducing attention mechanisms, the model learns the importance of target regions during training, improving the precision of target localization and counting accuracy.

4) Lightweight design: Prioritizing lightweight design for feasible deployment on edge devices, RLFDNet reduces the total number of network parameters, enhancing the model's inference efficiency. This design decision maintains counting performance while strengthening the model's adaptability in resource-constrained environments.

5) Environmental adaptability: Experimental details consider different shooting heights and environmental conditions, with the model employing a self-adaptive adjustment strategy. Learning richer features under varying conditions enhances adaptability to complex scenarios, crucial for practical rice panicle counting applications.

However, while RLFDNet significantly outperforms other advanced object detection methods in both accuracy and inference efficiency, it acknowledges certain limitations. Firstly, as the experiments were conducted at three specific altitudes (7m, 12m, and 20m), real-world applications may involve different shooting heights not covered in this study, potentially affecting inference results due to variations in panicle size and density. Secondly, variations in rice panicle phenotypes due to different rice varieties in different regions could result in suboptimal inference performance, highlighting the need for further research in addressing these limitations.

V. Conclusion

In this research, rice panicle localization and counting method named RLFDNet was designed and proposed. A concise and efficient encoder-decoder module was further developed within the model. A series of experiments demonstrated that RLFDNet achieved excellent results in rice panicle detection at different shooting heights, providing real-time and accurate localization and counting of rice panicles. With an MAE of 1.86 and an R^2 of 0.9461, the model showed robust performance. Considering various altitudes, the model achieved an average accuracy of mAP@0.5 at 0.91, with a total parameter count of only 4.40M. The inference efficiency reached 80.43 FPS, meeting the requirements for deployment on low-end edge devices. This provides a valuable tool for farmers and governments in assessing rice yields. In the future, exploration will be conducted to test the model with more shooting heights and different rice varieties to expand its capability to adapt to diverse environmental conditions, such as varying lighting and weather patterns, thereby enhancing its adaptability and reliability in real agricultural settings. The aim is to broaden its applicability across different countries and regions while addressing emerging challenges in agricultural technology.

***Abstract*—End milling process is widely used in various industrial applications, including health, aerospace and manufacturing industries. Over the years, machine technology of end milling has grown exponentially to attain the needs of various fields especially in manufacturing industry. The main concern of manufacturing industry is to obtain good quality products. The machined products quality is commonly correlated with the value of surface roughness (Ra), representing vital aspect that can influence overall machining performance. However, finding the optimal value of surface roughness is remain as a challenging task because it involves a lot of considerations on the cutting process especially the selection of suitable machining parameters and also cutting materials and workpiece. Hence, this study presents a support vector machine (SVM) prediction model to obtain the minimum Ra for end milling machining process. The prediction model was developed with three input parameters, namely feed rate, depth of cut and spindle speed, while Ra is the output parameter. The data of end milling is collected from the case studies based on the machining experimental with titanium alloy, workpiece and three types of cutting tools, namely uncoated carbide WC-Co (uncoated), common PVD-TiAlN (TiAlN) and Supernitride coating (SNTR). The prediction result has found that SVM is an effective prediction model by giving a better Ra value compared with experimental and regression results.**

Keywords—Support Vector Machine; surface roughness; end milling; Taguchi method

I. Introduction

A. Problem Background

In recent years, the machining process becomes important and widely used in manufacturing industries. With the highly competitive industries that have emerged nowadays, manufacturers compete with each other in delivering products of high quality with lower production costs. The effectiveness of the machining process relies on selecting appropriate cutting conditions, which is normally done by the machinists. Machining refers to a process of material removal from a workpiece in a chip form. Machining can be either conventional or non-conventional machining. Non-conventional machining is also considered as modern machining. The popular machining performances evaluated by the significant measure are surface roughness (Ra), tool wear, cutting force, strength, torque, chip shape, etc. Pan et al., [1] found that the machining performance that garnered the most attention from researchers is Ra. Ra is considered as a key factor to determine the surface quality of a product. This is due to the significant role of Ra in the performance of machine parts for wear resistance, ductility, tensile, and fatigue. Ra has a major effect on dimensional accuracy, mechanical parts efficiency and cost of production. Furthermore, Ra also affects the machining process stability diagnosis where a reduction of the surface quality can imply non-homogeneity of the workpiece surface, progressive wear of the tool and cutting tool chatter [2].

Ra is a product's measurement for technological quality and a feature that affects the production cost. Due to the advent development of technology, such as computing capability and data science, the researchers prefer to apply computational approaches to model the machining process [3]. Furthermore, due to the uncertainty and complexity of Ra, it is quite difficult to obtain the Ra value by the analytical equations. Computational approaches, including machine learning (ML) methods have become most interesting area of study, and researchers have shown tremendous interest in developing various models to improve the efficiency of measuring machining performances. ML approaches are capable to solve the optimal solution problem of the machining parameters with either the minimum or maximum machining performance. ML approaches that have been considered by previous studies include Support Vector Machine (SVM) [4]-[5], Artificial Neural Network (ANN) [6] – [7], Bayesian Network [8]-[9], Decision Tree [10], Random Forest [11], etc.

The key problem in the machining process is how to use various cutting conditions and machining parameters to achieve optimum solutions for the machining performances. These optimal solutions must be capable of minimizing the economic aspects of machining operations. Traditionally, during the machining process, the parameter selection for the cutting conditions was usually left to the machinist. However, this approach also relies on the machinist's skills. Furthermore, this traditional way of cutting method requires high production costs due to the fact that the material can only be used once. Machinists' experience also plays an important role, but often the optimum values for each experiment are difficult to preserve [12]. Hence, there is a need for the development of the computational approaches method in order to solve this problem. The technology growth has brought the ML approaches to be introduced to develop an improved model for the performances of the machining process. Using ML, it is easy to implement machine modelling instead of conventional techniques which are required a more complex physical understanding and knowledge of the machining process. The machining process can be completed in different approaches with the same objectives with the help of ML.

B. Proposed Prediction Model

This study proposed the integration of ML approach with Taguchi Method to prediction machining performance of end milling process. Selected ML approach, which is SVM is applied to estimate a minimum value of Ra in one of the mostly used machining process. SVM is based on the classifier of statistical learning theories [13]. SVM has demonstrated its capability when it delivered a better performance than ANN [14]. SVM has been widely applied in various fields such as health [15]-[16], agriculture [17]-[18], geology [19], and etc. In machining field, SVM has been extensively applied in various studies for the prediction of machining performances in conventional and non-conventional machining.

SVM was proven to give an effective prediction model for several of machining processes. Kumar et al [20] developed prediction models of Ra, cutting force, tangential force and tool wear in the boring process using SVM and response surface methodology (RSM). The machining experiment was carried out using full factorial design with workpiece AISI 4340 steels and multi-layered coated carbide electrode. The result shows that SVM has outperformed RSM for the prediction of machining parameters with the RMSE value of 0.039. Singh et al [21] applied SVM to predict the Ra value for the wired EDM (WEDM) process. The parameters namely servo voltage, pulse on time, pulse off time and peak current were used to develop a model. The experiment was carried out based on 3^k full factorial design. The prediction results show the minimum Ra value can be achieved using SVM approach.

Do Duc et al. [22] predicted the Ra value of 3X13 steel material in CNC hole turning process. The machining experimental was conducted based on DOE with feed rate, cutting speed, tool nose radius and cutting depth as the input parameters. The prediction models of RSM and SVM were developed, and results show that SVM model has outperformed RSM model by giving the mean absolute error (MAE) and mean square error (MSE) of 2.80 % and 0.17 %, respectively. Ramesh and Mani [23] applied SVM to predict the Ra value of abrasive waterjet milling (AWM) process. The experiments were carried out based on the RSM with Box-Behnken method. The input parameters were used to model the Ra are abrasive flow rate, pressure, the step over and the traverse rate. The optimal parameter values are then applied in the ε- SVM model to determine the minimum Ra in the AWM. The prediction result shows significant value of the training data accuracy. The prediction model then improved by tuning its hyperparameters using the fivefold cross validation. The result shows that SVM model has outperformed the quadratic regression model by giving accuracy of 92.4% compared to 70%.

From the review of the previous studies implemented by previous researchers, it can be concluded that SVM is able to give effective prediction results for conventional and modern machining processes. Furthermore, SVM has outperformed other techniques such as RSM and ANN [20], [24]. In the current work, the SVM prediction model is developed to predict the Ra value for end milling processes.

The remainder of this article is organized as follows. Section II discussed the materials and method of the study. It consists of experimental data and the approaches used in this study. Furthermore, the result and discussion were discussed in Section III and finally the conclusion is stated in Section IV.

II. Materials and Method

A. Experimental Data

The data used for the SVM prediction model is based on the actual machining experimental conducted by Mohruni [25]. The experiment was carried out using annealed alpha–beta titanium alloy workpiece and three types of cutting tools; “uncoated carbide WC-Co” (uncoated), “common PVD-TiAlN” (TiAlN) and “Supernitride coating” (SNTR). Cutting speed, feed rate and depth of cut were used as input parameters while Ra was the output parameter. The experiment was conducted based on a 2^3 factorial design. Table I shows the coded value ranges for each of the input parameters. The range values of coded parameters are levels -1, 0, and 1. The experimental data for surface roughness value which is measured using Taylor Hobson Surfronic +3, is given in Table II.

B. Taguchi Method

The experimental data as in Table II were analyzed based on the Taguchi method to obtain the significant parameters for the Ra values. The signal-to-noise (S/N) ratio of the Taguchi method was used as the quality characteristic of the parameters. Instead of standard deviation, the S/N ratio is used as a measurable value given the fact that the standard deviation often decreases as the mean decreases, and increases when the mean increases. This implies that it is impractical to minimize the standard deviation and get the mean target first. According to Salur et al., S/N ratio theory operates in two directions; reduction of variance and mean improvement. In addition, the S/N ratio is correlated with the impact of the factors on the response.

The S/N ratio value is computed based on performance characteristics whether it is larger-the-better, smaller-the-better or nominal-the-better, using Eq. (1) – Eq. (3).

Smaller-the-better:

$$S/N = -\log 10\ [\tfrac{1}{n}\sum_{i=1}^{n} y_i^2] \tag{1}$$

Larger-the-better:

$$S/N = -\log 10\ [\tfrac{1}{n}\sum_{i=1}^{n} \tfrac{1}{y_i^2}] \tag{2}$$

Nominal-the-better:

$$S/N = 10 \log\ [\tfrac{y}{s_y^2}] \tag{3}$$

where, *n* is a sample size and *y* is a sample value with i=1, 2, 3...n. Surface roughness value targets the minimum value for better performance, hence it applies the "smaller-the-better". Table III shows the S/N ratio for uncoated, TiAlN and SNTR end milling.

Based on the S/N ratio value in Table III, mean response table was developed for each level for all machining parameters. The ranking was determined for machining parameters at every level by considering the difference between the highest and lowest values. The higher rank shows that the Ra value is more affected by the parameter. Table IV shows the response table for Ra of uncoated end milling.

TABLE III. S/N RATIO FOR UNCOATED, TIALN AND SNTR

TABLE IV. RESPONSE TABLE FOR UNCOATED

Parameters	Cutting speed	Feed rate	Radial rake angle
Level			
Level -1	1.1334	1.6638	1.3881
Level -1.4142	0.8113	0.9836	0.8814
Level 0	4.1840	4.7036	4.3541
Level 1	1.5122	0.9817	1.2575
Level 1.4142	1.0391	0.3473	0.7989
Max-Min	3.3727	3.7219	3.4727
Rank	3	1	2

From Table IV, the feed rate is ranked first, followed by radial rake angle and cutting speed. Hence, it can be concluded that, feed rate is the most significant parameter while cutting speed is the least significant parameter for uncoated end milling. The optimal level for surface roughness value of uncoated end milling can be determined based on main effects plot, as shown in Fig. 1.

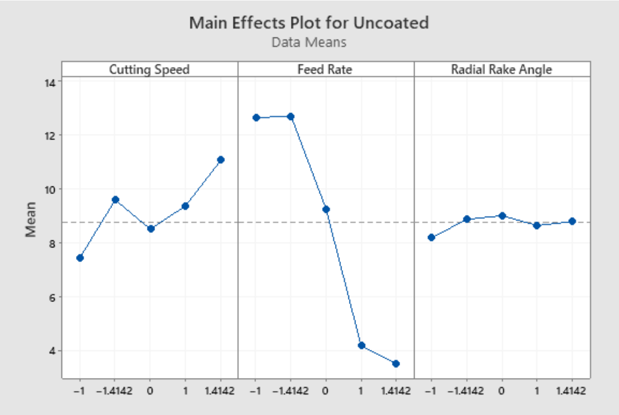

Fig. 1. Main effects plot for uncoated.

Based on the plot, it shows that the optimal solution of Ra for uncoated end milling is where cutting speed at level 1.4142 with 167.03 m/min, feed rate at level -1.4142 with 0.025 mm/tooth and input parameters radial rake angle at level 0 with 9.5°. Table V shows the response table for TiAlN. The table shows that input parameter feed rate is ranked first, trailed by input parameters cutting speed and radial rake angle. Hence, it can be concluded that feed rate is the most significant parameter while radial rake angle is the least significant parameter for TiAlN end milling. The optimal level for surface roughness value of TiAlN end milling can be determined from the main effects plot, as in Fig. 2.

From Fig. 2, the optimal solution can be determined for each of the parameters. The optimal level for TiAlN is where the input parameter cutting speed is at level 1 with 160 m/min, input parameter feed rate at level -1 with 0.03 mm/tooth and input parameter radial rake angle at level -1.4142 with 14.8°. Table VI shows the response table for SNTR and Fig. 3 shows the optimal level for surface roughness value of SNTR.

From Fig. 3, the optimal solution for SNTR can be determined for each of the parameters. The optimal level for SNTR is where the input parameter cutting speed is at level 1.4142 with 167.03 m/min, input parameter feed rate at level -1.4142 with 0.025 mm/tooth and input parameter radial rake angle at level 0 with 9.5°. Based on the response tables for uncoated, TiAlN and SNTR, it can be concluded that feed rate is the most significant parameter for end milling machining process. Feed rate ranked first for all these three coatings. Based on the main effects plots, the optimal level for end milling differs for each of the coating's types.

C. *Support Vector Machine (SVM)*

SVM was initially proposed by Vapnik [13]. Adapting the concept of Structural Risk Minimization (SRM), SVM is able to obtain rules for decision-making and allow minor errors in setting independent tests so that learning problems can be effectively solved. Basically, SVM prediction model consists of five major steps, which are illustrated in Fig. 4.

The basic SVM regression function theory is presented in Eq. (4) [13].

$$y = f\,(x) = \rceil .\ x + b \qquad (4)$$

Max-Min	3.0095	3.9255	3.1377
Rank	3	1	2

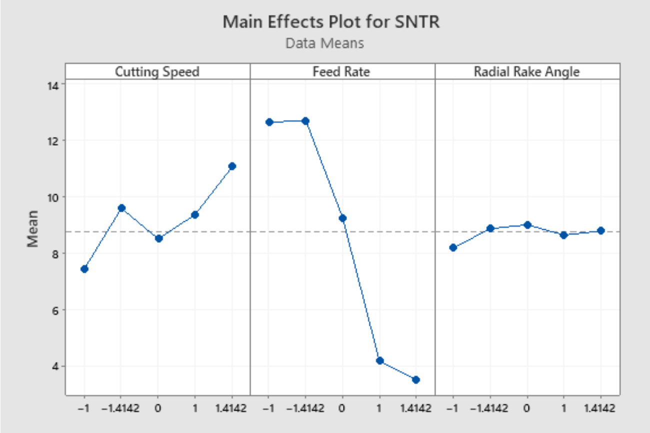

Fig. 3. Main effects Plot for SNTR.

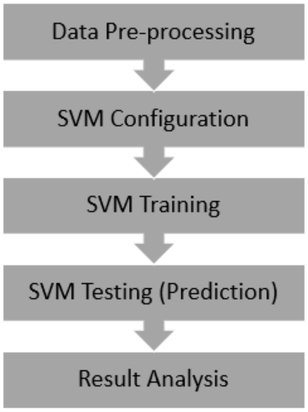

Fig. 4. Steps in SVM.

where, ω is a weight vectors, x is multivariate input, b is a bias, and y is a scalar output. Then, slack variables $\xi_i and\ \xi_i^*$ are introduced to the equation, the SVM model is expressed as:

Minimize

$$\phi(\omega) = \frac{1}{2}||\omega||^2 - C\sum_{i=1}^{n}(\xi_i - \xi_i^*) \cdot C \geq 0$$

$$y - \omega x - b \leq \varepsilon + \xi,$$

Subject to

$$\omega x - b - y \leq \varepsilon + \xi_i^*, \quad i = 1,2,\ldots,l$$

$$\xi_i, \xi_i^* \geq 0, \tag{5}$$

where, ε is a loss function, and C is a regularization parameter.

$$y = f(x) = \sum_{i=1}^{n}(\alpha_i - \alpha_i^*)(x_i \cdot x) + b \tag{6}$$

SVM model solution is obtained by applying the Lagrange Multiplier method as the following equations:

$$L(\omega, b, \xi, \xi^*) = \frac{1}{2}\ ||\omega||^2 + C\ \sum_{i=1}^{n}(\xi_i - \xi_i^*) - \sum_{i=1}^{n}\alpha_i(\varepsilon_i + \xi_i - y_i + \omega \cdot x_i + b) - \sum_{i=1}^{n}\alpha * (y_i + \varepsilon_i + \xi_i - \omega \cdot x_i - b) - \sum_{i=1}^{n}(\eta_i\xi_i + \eta_i^*\xi_i^*) \tag{7}$$

where, $\alpha_i, a_i^*, \eta_i, \eta_i^*$ are the Lagrange Multiplier. Then, the dual problem is:

Maximize

$$Q(\alpha) = \sum_{i=1}^{n} y(\alpha_i - \alpha_i^*) - \varepsilon\sum_{i=1}^{n}(\alpha_i - a_i^*) - \frac{1}{2}\sum_{i=1}^{n}(a_i - a_i^*)(x_i - x_j) \tag{8}$$

Subject to

$$\{\sum_{i=1}^{n} y_i(a_i - a_i{}^*) = 0, 0 \leq a_i \leq 0, \quad 0 \leq a_i{}^* \leq 0,$$

$$i = 1,2,\ldots,n$$

Regression function:

$$f(x) = \sum_{i=1}^{n}(a_i - a_i{}^*)(x_i, x) + b \tag{9}$$

Nonlinear regression function:

$$f(x) = \sum_{i=1}^{n}(a_i - a_i{}^*)\, K(x_i, x) + b \tag{10}$$

The solution of K (x_i, x) in the Eq. (9) can be changed into K(x_i,x) = (∏(x_i),⎞(x)) when using a mapping function. From the equation, *n* is the number of support vectors, K is a kernel function and b is bias. The high-accuracy prediction and good SVM model come with a proper parameter setting. RBF kernel function is used in this paper to predict the Ra of the end milling machining process.

For the SVM data pre-processing, the machining experimental dataset is divided into two datasets: one is for training and the other one is for testing that will be used to get the prediction result. The input data of training and testing data need to be transformed into a sparse format in range [0, 1]. For the SVM configuration, kernel function, Gamma value (for RBF kernel) and regularization parameter C need to be considered. The process of trial and error with different parameter values must be implemented accordingly to get the best prediction model. After completing the training and testing process, the prediction result is analyzed using statistical analysis.

III. Result and Discussion

The SVM prediction models were developed and three models were identified as the best prediction model for all three cutting tools. The models were chosen based on the highest correlation values of developed SVM models. Table VII shows the predicted Ra value of regression based on the result from Zain et al. and SVM.

TABLE VII. RA Values of Predicted Regression and SVM Predictions

No	Predicted *Ra* (µm) Regression			Predicted *Ra* (µm) SVM

19	0.580	0.563	0.691	0.5894	0.7200	0.6874
20	0.580	0.563	0.691	0.4988	0.5709	0.6353
21	0.355	0.382	0.374	0.2269	0.2371	0.2300
22	0.355	0.382	0.374	0.5996	**0.1910**	0.1663
23	0.395	0.334	0.361	0.4728	0.4871	0.6916
24	0.395	0.334	0.361	0.4094	0.4539	0.6385

From Table VII, it shows that, for uncoated, SVM prediction result has outperformed experimental data and regression by giving the Ra value of 0.1275µm, compared with 0.236µm and 0.226µm, respectively. For TiAlN coating, it was found that the SVM prediction result has outperformed experimental data and regression by giving the Ra value of 0.1910µm, compared with 0.232µm and 0.245µm, respectively. For SNTR coating, it was found that the SVM prediction result also has outperformed experimental data and regression by giving the Ra value of 0.1372µm, compared with 0.19µm and 0.187µm, respectively. The graft of prediction result is illustrated in Fig. 5- Fig. 7.

Fig. 5 – Fig. 7 show the graphs of comparison of experimental data, regression and SVM prediction. The prediction results of SVM were then validated based on the statistical analysis using SPSS software to find the accuracy of each model. Table VIII shows input parameters with RMSE values for the best SVM models while Table IX shows the paired sample t-test for each coating types to compare the SVM prediction with experimental data.

It can be seen in Table IX that all pairs are positively correlated with pair of EXP_ SNTR and SVM_SNTR gives the highest correlation value, 0.9682. A good prediction result will give a higher correlation value for each pair. A higher correlation value means that two sets of data are relatively similar to each other. Table X summarizes the result of most minimum Ra values for each coating tool for experimental data, regression and SVM models.

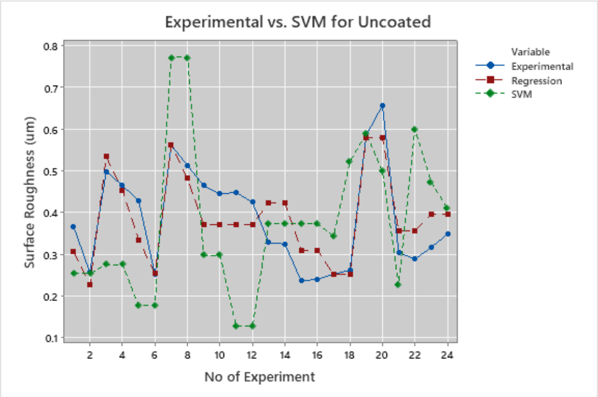

Fig. 5. Experimental vs. SVM for uncoated.

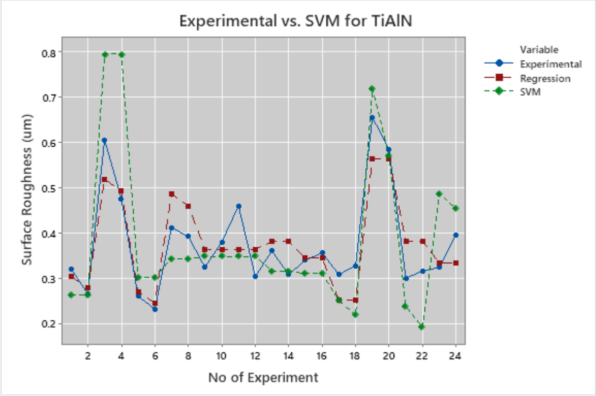

Fig. 6. Experimental vs. SVM for TiAlN.

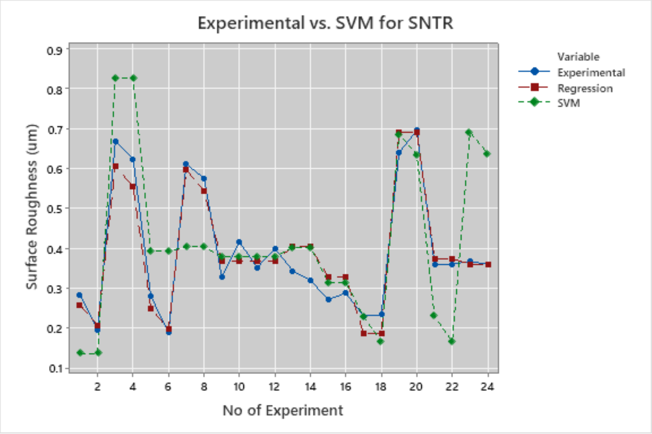

Fig. 7. Experimental vs. SVM for SNTR.

TABLE VIII. INPUT PARAMETERS AND RMSE VALUES FOR THE BEST SVM MODEL

Coating	C	Gamma	No. of support vector	RMSE
Uncoated	100	0.4	78	0.0739
TiAlN	100	0.333	34	0.0650
SNTR	1	0.333	20	0.0634

TABLE IX. PAIRED SAMPLE T-TEST

Paired Sample T-Test						
Pairs	Mean	Standard Deviation	Standard Error Mean	95% Confidence Interval		Correlation
				Lower	Upper	
EXP_UNC and SVM_UNC	0.0128	0.1846	0.0378	-0.0653	0.0904	0.9485
EXP_TIAN and SVM_TIAN	-0.0072	0.1031	0.0210	-0.0508	0.0363	0.9468
EXP_ SNTR and SVM_SNTR	-0.0218	0.1433	0.0292	-0.0823	0.0388	0.9682

TABLE X. MINIMUM RA VALUES IN END MILLING FOR EACH APPROACH

Approach	Uncoated (µm)	TiAlN (µm)	SNTR (µm)
Experimental	0.236	0.232	0.190
Regression	0.226	0.245	0.187
SVM	0.127	0.191	0.133

From Table X, it is shown that SVM model has outperformed experimental and regression model for uncoated, TiAlN and SNTR cutting tools in terms of minimum value of Ra. The minimum Ra has reduced for both regression and SVM about 1.57% and 33.05% respectively. Overall, it could be concluded that SVM is effective to predict the most minimum Ra value of end milling machining process.

IV. CONCLUSIONS

This study utilized the computational approaches method, Taguchi and SVM for modeling and optimization of surface roughness value in one of the traditional machining process, which is end milling. Three types of cutting tools were used to obtain the experimental data that are uncoated carbide WC-Co, common PVD-TiAlN and Supernitride (SNTR) coating. The significant parameters affecting the end milling performance, surface roughness values were obtained using the S/N ratio of the Taguchi method. From the study, it was found that:

1) Input parameter feed rate is the most significant factor affecting surface roughness value for all types of cutting tools.

2) The optimal level for uncoated end milling is where the input parameter cutting speed at level 1.4142 with 167.03 m/min, and input parameter feed rate at level -1.4142 with 0.025 mm/tooth and input parameter radial rake angle at level 0 with 9.5°.

3) The optimal level for TiAlN is where the input parameter cutting speed is at level 1 with 160 m/min, input parameter feed rate at level -1 with 0.03 mm/tooth and input parameter radial rake angle at level -1.4142 with 14.8°.

4) The optimal level for SNTR is where the input parameter cutting speed is at level 1.4142 with 167.03 m/min, the input parameter feed rate at level -1.4142 with 0.025 mm/tooth and the input parameter radial rake angle at level 0 with 9.5°.

5) For the end milling prediction, it has been found that SVM gives better prediction results compared with regression and experimental data for all three types of cutting tools.

6) Within these three cutting tools, uncoated cutting tools give the most minimum Ra which is 0.127µm compared to TiAlN and SNTR, 1.9µm and 1.32µm, respectively. Hence, it can be concluded that the uncoated cutting tool is the best cutting tool amongst the three types of cutting tools that are widely used in traditional machining process, especially end milling.

ACKNOWLEDGMENT

We would like to thank Universiti Malaysia Terengganu for the support and funding for this project under the Grant No. of UMT/TAPE-RG 2021/Vot 55415.

Abstract*—Songket is a fine art heritage specializing in promoting the unique features of Malay identity. Past studies have shown that hundreds of Songket motifs had been produced, but unfortunately, most were not stored digitally. However, the digital collection of image data and determining its ground truth data should be given attention. This paper focuses on an evaluation metric to retrieve image Songket motifs. The initial label for each class of images in the database is ground truth data. The activity of determining the ground truth data involves two research objectives that have been discussed, namely identifying the ground truth data set of Songket Motifs involving Activity One, to obtain two ground truth data sets, precisely the training data set and the test data set involving six categories, to be specific 'Flora', 'Fauna', 'Nature', 'Cosmos', 'Food' and 'Calligraphy'. This phase test was carried out through a survey using a qualitative method, which is participatory by 15 respondents who have classified 413 specific motif images into 56 Songket motifs categories that refer to the six prominent motifs. Meanwhile, Activity Two is a validation-classification test of ground truth data sets by three experts to equate the selection of general and expert respondents to obtain training data sets for testing purposes involving six categories. After rearranging, only 50 ground truth Specific Motifs have been selected. Accordingly, the relationship coefficient correlation method is also implemented to see the relationship between two data through a statistical evaluation angle. In addition, precision and recall methods are also used to obtain precision and recall values for each ground truth data, and the F-measurement method is used to make a single evaluation. The F-measurement result for each category 'Flora': 26.7 – 100 (20 ID-Category), 'Fauna': 35.3 – 100 (6 ID-Category), 'Nature': 30.8 – 100 (5 ID-Category), 'Cosmos': 53.3 – 100 (7 ID-Category), and 'Motif': 47.6 – 100 (9 ID-Category). Using ground truth data enables image retrieval research to conduct unbiased system testing and evaluation.

***Keywords*—Heritage; songket motifs; songket motifs retrieval; ground truth data**

I. Introduction

Malaysia has a rich cultural and artistic heritage that can be divided into two categories: tangible cultural heritage and intangible cultural heritage. Tangible cultural heritage refers to physical objects that can be seen and touched, such as tombs and tombstones. On the other hand, intangible cultural heritage is based on knowledge and expertise that is passed down through oral traditions, cultural values, language, literature, and textiles, such as the traditional Songket [1]. Researchers have explored the use of the Content-Based Image Retrieval (CBIR) technique to study the Songket in intangible cultural heritage. Some of the research focuses on determining the basic geometric structure [2], decomposing the Songket Motif texture to match motif similarity [3], and refining the boundaries of Songket Motif images using canny edge detection techniques [4].

The study conducted by [2] and [3] focuses on the image retrieval model, which includes three main stages: pre-processing, processing, and post-processing. In this model, the pre-processing stage is particularly important as it involves the preparation of datasets, whether they are original or synthetic. Obtaining original data is a more challenging task as it requires the collection of images using a camera lens and converting them into digital format through editing. Therefore, researchers must put in extra effort to locate individuals or groups who actively use the data, such as Songket entrepreneurs and researchers.

According to the viewpoint put forth by [5], most of the information regarding Songket is still reliant on traditional methods, such as documentation and bookkeeping. Therefore, to conduct this study, it is imperative to undertake measures to digitize the information related to Songket. In the meantime, synthetic data can be obtained by downloading it from websites or producing it oneself, such as through paintings or anime, among others [6].

The image pre-processing stage involves two main parts: the determination of the ground truth data and the development of the image segmentation system [7]. Ground truth data is a set of master images that represent each image class in the database [8]. Determining the ground truth data helps in testing the image retrieval system more effectively. This process is carried out either based on human observation or by the system itself [9, 10]. The initial label for each class of images in the database is the ground truth data [8]. The use of ground truth data enables unbiased system testing and evaluation in image retrieval research [9]. Ground truth data can be established either by the system or through human observation [2, 3].

The image pre-processing stage was a significant focus of the study when Songket Motif's image retrieval model was introduced in references [2] and [3]. Image pre-processing involves determining the ground truth data and image segmentation. However, the determination of Songket Motif's ground truth data has not received enough attention, and most researchers perform testing by randomly selecting the Songket Motif. The goal of determining the ground truth data is to help in the fair processing of the image retrieval system's searching and browsing functionality.

The following text discusses the concept of ground truth data sets in research and their importance in producing accurate results. Specifically, the paper aims to determine ground truth data sets for Songket Motifs. To achieve this goal, both qualitative and quantitative methodologies are employed. Earlier studies, including [3, 8, 2], have also identified ground truth data sets for their research. However, this paper focuses solely on the Songket Motifs and their ground truth data sets. It is worth noting that the ground truth data set is a collection of data that has been established as authentic by either the user or the system. Its purpose is to ensure that the results obtained are reliable and trustworthy.

This paper is divided into five sections. The first section is an introduction and overview that discusses ground truth data determination along with any issues, objectives, and research methodologies. In the literature review section, key points from the literature are covered in detail and with a critical discussion. The third section focuses on the research methodology used to gather precise information about Songket Motifs. The fourth section deals with selecting experts and general users for the research. The fifth section contains the results and discussion, and the conclusion and acknowledgment follow afterward.

II. Literature Review

The main images in computer vision typically serve as a group representation for each image. They contain ground truth data, which is meant to show the essential components of each object in the image collection [9]. The primary label outlines the critical component of the object and its location in the image. As stated in [13], humans or systems must decide how to classify objects. Some commonly asked questions regarding identifying ground truth data include:

1) How ground truth data has been detected?

2) If using the system, is the first image ground truth data?

3) How has the system detected ground truth data?

4) If humans have detected ground truth data? What is the characteristic of expertise to be able to confirm it?

A study conducted by [9] utilized 80 general and eight expert participants to gather ground data based on human perception. The general participants were asked to identify relevant and commonly used English labels while searching and browsing landscape drawings. Meanwhile, the expert participants were tasked to provide the appropriate keyword for the ground truth data that could accurately describe each color notion evaluated in the landscape painting.

Furthermore, according to [10], establishing ground truth data by human observation is a challenging endeavor that takes much time. Different definitions and meanings exist of human perception and response to an object in an image [9]. To ensure that the ground truth data used is balanced to represent each category of variable data, however, human observation and the ability to determine the ground truth data are necessary [12].

Accordingly, geometrical data faces issues describing complex data structures and is even challenging to detail geometrically by natural data systems [10]. Thus, human observation of the shape structure is found to help facilitate the process of determining the ground truth data. In addition, the process of determining ground truth data can also determine the selection of labels or words of ground truth data required to implement tests at the testing stage of the proposed model and system [14]. This aims to enable the implementation of the evaluation and comparison of image retrieval results to take place somewhat and equitably for testing the image retrieval system.

III. Method

This phase involves two levels of activity. Activity One aims to identify the ground truth data set of Songket Motifs. Meanwhile, Activity Two is a ground truth data set classification process involving Songket Motif's images.

A. Identify Songket Motif's Ground Truth Data Set

This activity takes the form of a participatory test to determine the Songket Motif's data set in obtaining the ground truth data set, which is a participatory survey of human observation of form, where respondents must classify 413 images into six Songket Motif's categories, namely 'Flora', 'Fauna', 'Nature', 'Cosmos', 'Food' and 'Calligraphy'.

The respondents consisted of 15 users from two different backgrounds; Culture (directly involved in Songket research) and Information Technology. Respondents from the Cultural field are needed because they are more adept at identifying the structure of the ground truth data involving Songket Motifs. Meanwhile, respondents in the Information Technology field are more sensitive to the similarity of the shapes they see. Table I shows the background of the respondents.

TABLE I. Background of the Respondents

Occupations	Gender	Field
Student (1)	Female (8)	Culture (Songket Weaving) (11)
Work (14)	Male (7)	Information Technology (4)

Respondents were selected based on their knowledge of the form and motifs of Songket to conduct the test. Eight out of 15 respondents (53.3%) were female, while seven (46.6%) were male. All respondents were between 25 and 60 years old. The study aims to obtain a collective initial result to continue the system testing by classifying Songket Motif's data sets to ground truth data sets.

1) Research activity design: Based on Table II, this section is a further detail involving two Activities.

TABLE II. Aim and Method

Label	Research	Aim	Method
Activity One	Identifying the ground truth data set of Songket Motif's	Gets two sets of ground truth data, namely the set training data and test data involving six Songket Motif's categories ('Flora', 'Fauna', 'Nature', 'Cosmos', 'Food', and 'Calligraphy')	Qualitative method survey: Participatory. 15 respondents categorized 413 images involving six Songket Motif categories
Activity Two	Validation of ground truth data set classification	Validating a training data set for testing and evaluation purposes involves five categories ('Flora', 'Fauna', 'Nature', 'Cosmos', and 'Motifs')	Validation and use of training data sets (50 Songket Motif's). Comparison of F-measurement for five categories.

Fig. 1. Flow chart of activities identifying the ground truth data set of Songket Motif's.

Identifying the ground truth data set of Songket Motifs refers to the flow chart displayed in Fig. 1. Each respondent was given a brief description of the task that needed to be carried out. After that, respondents were required to classify 413 Songket Motif images into six Songket Motif categories.

Activities are conducted using the same computer for each respondent in each session under the researcher's supervision. This aims to make it easier for respondents if there are questions on unclear matters. The specific Motif's image sizes are varied, and all specific motifs are labeled in numerical order from 001 to 413.

Respondents were free to choose shapes that were considered similar from a selection of specific Motif's image categories. Respondents must provide feedback for each page before the system allows the display of the next screen. This aims to ensure respondents provide feedback for all screen displays of the questions.

The test results show that the respondent's time to classify the similarity of 413 specific Motif images was more than 60 minutes, and the respondent's concentration decreased over time. Therefore, the number of specific Motif images was reduced to 200, and this test was divided into two sessions to ensure that the respondent's focus could be maintained as well as possible to obtain valid results.

All responses from respondents are recorded directly into an online file. Updates to this file are done automatically whenever there is feedback from respondents.

Fig. 2 displays an example of a participatory survey question for the two earliest examples of specific Motifs for sections One and Two with image IDs labeled 001-100. Respondents must choose to match the similarity of images that are seen to have similar shapes. If the respondent does not provide feedback, the respondent cannot press the "Submit" button because each question is marked * as a "Required question." Respondents' choice of matching answers can exceed more than one image for each group.

(B) Section Two

Fig. 2. An example of a participatory survey question on the classification of Songket Motif's.

2) Validation of classification of ground truth data sets: Validation technique activities are carried out to validate or cross-check the ground truth data set of Songket Motifs identified in the previous phase. Table III is the background of the respondents involved in verifying the ground truth data arrangement of Songket Motifs according to different categories. The respondents consisted of three experts in the field of Culture (studying Songket and Batik) and Information Technology (conducting research involving image retrieval technology and Songket motifs), aged between 35 and 46 years. Because the respondents are experts, it is used as purposive sampling in Activity Two, that is, verification - classification of ground truth data sets.

This phase involves human evaluation of the appearance of specific motifs. The activities of this section are labeled as Activity Two and are carried out to achieve the objective of this study. Activity Two involved validation in identifying similar features of specific Motif shapes and evaluation of the confusion matrix. The two research questions for this phase are listed as follows to ensure that this activity achieves results.

TABLE III. RESPONDENT BACKGROUND

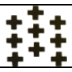
Respondent	Gender	Age	Field
Respondent #01	F	46 Years Old	Senior Lecturer in Information Technology & Songket
Respondent #02	F	37 Years Old	Lecturer in Heritage (Songket Researcher)
Respondent #03	F	35 Years Old	Researcher (Information Technology & Songket)

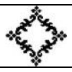
1) Is there a difference in the observation of specific Motifs between expert users and general users?

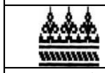
2) What are the results of the validation?

a) Validation test design – songket Motif’s classification: Songket motifs that general respondents have classified are 56 specific Songket motifs rearranged as in Table IV.

TABLE IV. SPECIFIC MOTIFS THAT THE GENERAL RESPONDENT HAS REARRANGED

Biji Tamar	Cermai	Nanas	Nona	Buah Delima
				Cendawan	Pucuk	Pucuk Rebung	Sulur Kacang	Bunga Bintang
Bunga Bebaling	Bunga Ros Meletak	Kembang Semangkuk	Kemunting Cina	Melur
Pecah Empat	Tampuk Kecupu	Tampuk Kesemak	Tampuk Manggis	Tanjung
				


Bunga Kekwa	Bunga Flora	Bunga Kemuncup	Daun	Daun Keladi
				Daun Lalang	Cengkeh	Peria	Burung Merak	Kupu-kupu
				


Siku Keluang	Gigi Yu	Rantai Unduk Laut	Unduk Laut	Sinar Matahari
Sirik	Bogan	Bunga Mahkota	Bunga Mangga	Pecah Lapan
				Bunga Tudung Saji	Petak Catur	Pitis	Semangat	Mahkota Raja
Keris	Cabit	Awan Larat	Kendik Tali	Ombak
				
Kaligrafi	Madu Manis	Potong Wajik	Tepung Talam	Seri Kaya
				


Motif				

The results of the selection of general respondents have been rearranged and make the total number of Songket Motif’s used 413 involving 56 specific Songket Motif's, and each has been classified similarly to 413 specific Motif, and the number of specific motifs classified is between two to 52 specific Songket Motif’s images.

All specific Motif are printed on A4 size paper, and the size measurement for each specific Motif’s image is 2.7cm, intended to help expert respondents see each specific Motif’s image well. Meanwhile, activities are done individually in the same or different rooms. Before undergoing Activity Two, respondent information such as name, age, and gender is recorded. Then, the purpose of Activity Two and what the respondent needs to do are explained to the respondent. After the description related to the task was clarified, the expert respondents were shown 56 images of specific motifs, and the classification results that the general respondents had carried out are shown in Fig. 3.

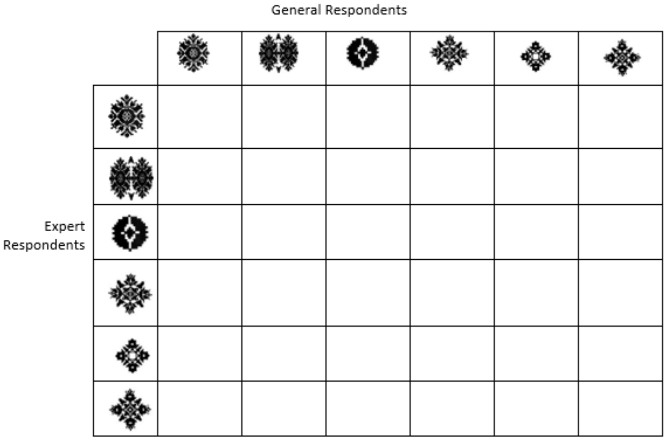


Fig. 3. Examples of specific Motif’s image categories and classification results that general respondents have implemented.

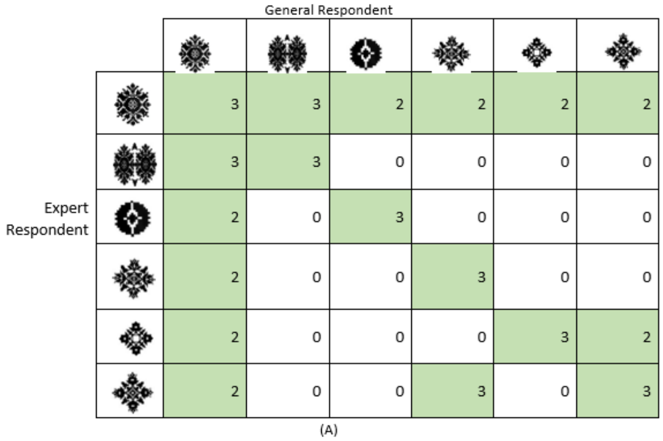
After expert respondents carry out the reclassification test, the ground truth data classification of the Songket Motifs is evaluated by calculating the confusion matrix formula, that is, using the technique formula of precision, recall, and F-measurement. The result of the selection of general respondents is the image in the database and all images achieved. Meanwhile, the selection of expert respondents is a relevant image. Accordingly, Fig. 4 shows that the column marked with the number two or three is a Songket Motif considered relevant by expert respondents. At the same time, the space marked with a blank (0) is a Songket Motif that is considered irrelevant. In Fig. 4(A), there are expert respondents (actual class) and general respondents (predicted class).

Next, Fig. 4(B) refers to the specific motifs in the first column displaying the highest F-measurement value, while the F-measurement value for the other specific Motif is lower. Therefore, for the specific Motif of 'Kembang Semangkuk' only one specific motif was selected as the ground truth data of the Songket Motifs for testing purposes.

A detailed description of this section is explained in the next section, which is the section on verifying the ground truth data analysis, and precisely in the next section.



3	3	2	2	2	2
3	3	0	0	0	0

Fig. 4. Evaluation of the confusion matrix for the ground truth data Songket Motif's class 'Kembang Semangkuk' (A) Mark the confusion matrix (B) Calculation.

IV. Results and Discussion

Through the reclassification activity of ground truth data selection by expert respondents, 364 (88.14%) Songket Motifs were classified into 50 categories. The 50 classified categories refer to the structural similarity of specific motifs considered relevant by respondents. At the same time, another 49 (11.9%) motifs could not be classified because there was no matching of similar characteristics for different Motifs the respondent could implement. This is because the specific motifs stand alone, for example, the specific Motif 'Ayam Jantan', although there are other specific motifs that can be classified in the same class (birds), namely the specific Motif 'Itik Serati'. However, the similarity of the specific motifs is seen as the difference is too far. Therefore, such images cannot be considered in the same class. Table V. shows the name and amount for each specific Motif reclassified through expert respondent verification and confusion matrix evaluation. The results of this evaluation show that 50 categories of ground truth Songket Motif's data were obtained.

The ground truth data analysis process of Songket motifs was carried out after the participatory survey was completed; 56 categories of Songket Motifs classified by general respondents were rearranged by expert respondents into 50 categories of actual Songket Motifs data. This is because general respondents randomly arranged each specific Motif into 56 categories. Meantime, the expert respondents rearranged the motives based on the appropriateness of the actual structure of the Motifs according to the category. Therefore, the critical analysis required for this activity is the frequency distribution of 50 similar appearance categories for each of 413 specific Motifs and the percentage of agreement between respondents who agree to set a similar appearance for each specific Motif. Table VI is an example of the frequency distribution for 20 Songket Motif images taken from the test involving the first and last 10 results.

The Songket Motifs involved are the first ten Songket Motifs labeled ID-Image between 001 to 010 and the last 10 Songket Motifs labeled ID-Image between 404 to 413. ID-Image represents the identification of each specific Motif in the database. In contrast, the ID-Category represents the identification of the identity of each image of the ground truth data of the Songket Motifs that has been determined. Based on the frequency distribution, some information can be deciphered, such as ID-Image 002, categorized as a similar match for ID-Category 001 by 15 respondents. While referring to ID-Image 412-413, eight respondents stated that it was similar to ID-Category 013. This test found that the higher the number of respondents who made a mark, the more similar a form of ID-Category was to the marked ID-Image.

TABLE V. A Group of Songket motifs that Expert Respondents have Classified

Bil	Motif's	Total		Bil	Motif's	Total
001	Anggur	8		026	Motif	6
002	Awan Larat	5		027	Motif	5
003	Bunga Bintang	12		028	Motif	8

046																					15
047																					
048																					
049																					
050																					

🟨 The respondent records no information for 20 ID-Image (016-037)

The minimum amount considered for the similarity percentage is eight respondents, equal to 53.3%, more than 50% of the respondents' agreement. The yellow column in Table VI refers to the ID-Category between 016 and 037, which means there is no matching information of specific Motif's image similarity done by the respondents for the ID-Category.

The highest frequency for each specific Motif shows the percentage of respondents who agree to classify the specific Motifs into a particular category. Some specific motifs get a higher or lower percentage of respondents' approval than others. Table VII shows the average value of the respondent's agreement evaluated through the results of the frequency distribution test, so the overall average value of the respondent's agreement amounts to 79.2%, categorized as ID-Category 001. However, the percentage of agreement of each ID-Category is different. For example, ID-Category 002, 020, and 037 have the highest agreement, 100%. All 15 respondents agreed that the specific Motif's match was similar. As for ID-image 041, the percentage of respondents' approval was only recorded at 63% for nine images, which is the lowest average value compared to other ID categories. The division of ID-Category 041 involves several parts, namely one image agreed upon by 15 respondents that is similar. In addition, two other images were agreed by 11 respondents that are like ID-Category 041. Simultaneously, there are six more Songket Motif images, with only eight respondents agreeing that they are similar, and the total number of respondents who agree is 85 out of 135. The number of similar images for ID-Category 041 is as many as nine specific motifs.

TABLE VII. SUMMARY OF THE AVERAGE VALUE OF THE RESPONDENTS' AGREEMENT EVALUATED THROUGH THE RESULTS OF THE FREQUENCY DISTRIBUTION TEST

ID-Category	Similar Image Matches for each ID-Category	Total Number of Respondents Consent	Actual Total Mark	Average Value of Respondents' Agreement (%)

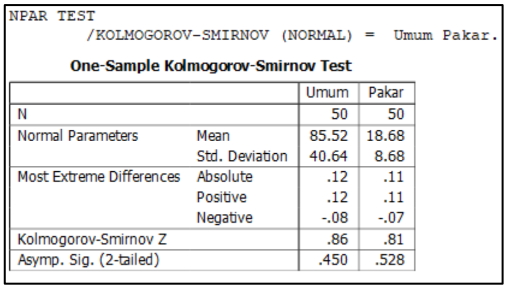
Accordingly, the correlation between general and expert respondents must be assessed using statistical methods. This aims to see the relationship between the two data that have been used.

A. *Correlation between the Selection of General Respondents and Expert Respondents*

To identify the relationship between the selection of general and expert respondents, the implementation of the relationship correlation test is one of the statistical methods often used [15]. The correlation test of the relationship coefficient using the 'Pearson Correlation method can be carried out, but it is necessary to go through a standard data determination test to see the P-Value *(Asymp. Sig(2 Tailed))* between the data of general respondents and expert respondents [16]. Accordingly, Table VIII shows the results of the selection of general respondents and expert respondents.

Based on Table VIII, the frequency distribution data test was carried out, and the results are displayed in Figure 5. According to [11], the P-value *(Asymp. Sig(2 Tailed))* obtained through the Kolmogorov Smirnov test needs to exceed 0.5% to enable the 'Pearson Correlation' method to be implemented. Thus, the evaluation results show that the data distribution for general and expert respondents is above 0.5%, which is general .450 and expert .528. Therefore, the results of the frequency distribution for this study are in a normal state. Therefore, the 'Pearson Correlation' method can be used for this study.



```

```

Fig. 5. The test results used one sample Kolmogorov – Smirnov for the entire general election, and respondents showed a P-value exceeding 0.05%.

Referring to Fig. 5, the implementation of the relationship coefficient correlation evaluation has used the 'Pearson Correlation formula, which considers the correlation coefficient value *(r)*, the *N* value, the statistical *T* value, the *DF* value, and the *P* value. The *DF* value is the *'degree of freedom'* that indicates the number of independent values that can change in the analysis without violating any constraint 11]. Whereas the value of N is paired ranks' value the value of *N* I is required to calculate the statistical T formula. The T-Statistic formula is like1).

$$t = \frac{r * \sqrt{n-2}}{\sqrt{1-r^2}} \quad (1)$$

The correlation value of a good relationship should be between *-1 < r < +1* [12]. Accordingly, Fig. 6 shows the results of the evaluation that was carried out, obtaining a value of 0.991a. Thus, the results of the relationship coefficient correlation for this study show that there is a positive relationship coefficient correlation between general *(Umum)* respondents and expert *(Pakar)* respondents.

a. Significant at .05 level

Fig. 6. The result of the Pearson Correlation value for general respondents is 1.00. while expert respondents are 0.991a.

Based on a comprehensive correlation coefficient test of fifty data between general and expert respondents, it was found that ID-Category 016, 018, 026, 035, 045, and 046 obtained the highest correlation coefficient result, which is one (1), the ID-Category representing specific Motif's 'Pergunungan1', 'Pergunungan2', ' Motif's ', 'Pagar', 'Kendik Tali', and 'Kendik Sirik'. Meanwhile, the other ID-Category obtained lower correlation coefficient results ranging from 0.65 to 0.95.

Furthermore, the ground truth data analysis part of the Songket Motif is a statistical information extract on matching similar images carried out by 15 general respondents and has been rearranged by expert respondents. After that, the similarity matching results were evaluated using confusion matrix analysis.

B. *Confusion Matrix Analysis of the Ground Truth Data of the Songket Motif's*

Songket motifs comprise six main categories: 'Flora', 'Fauna', 'Nature', 'Cosmos', 'Food', and 'Calligraphy' Motifs. Three prominent motifs have split motifs; the main motif 'Flora' is divided into six split motifs, namely 'Fruits', 'Trees', 'Flowers', 'Leaves', 'Spices', and 'Vegetables'. The main motif of the fauna is divided into two fractional motifs, namely 'Land' and 'Sea'. As for the main motif, 'Nature' is divided into two Motifs: ' Natural' and 'Things'. The main Motif of 'Cosmos' consists of three specific motifs; ' Awan Larat', 'Kendik Tali', and 'Ombak'; the total number of Songket Motif images for this category is 15 Songket Motif's images. However, the categories 'Food' and 'Calligraphy' were not chosen as the ground truth data of Songket Motifs because these motifs are rarely operated in any pattern commercially.

1) Songket Motif's category: The selection of Songket Motif's classification was done by respondents through the Activity One test, which identified the ground truth data set of Songket Motif. The re-determination of the ground truth data classification of Songket motifs by expert respondents was evaluated through a comprehensive confusion matrix calculation and is detailed in this section.

The confusion matrix technique's evaluation process is based on the criteria chosen by the respondents and categorized as images in the prediction class. Concurrently, images in the ground truth group of Songket Motifs are categorized as accurate class data. Once the confusion matrix evaluation table is completed, the matching process that the respondent has selected is carried out to enable the calculation process using the confusion matrix technique to be carried out. According to [9, 17], the advantage of the confusion matrix is that it can analyze the performance of each classifier in detail, even if the data set is unbalanced.

The performance measures often used are precision, recall, and F-measurement techniques. F-measurement evaluation is performed using True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN) matrix values. The value of this matrix is evaluated for each class based on the obtained confusion matrix table [2, 13].

The definitions of TP, TN, FP, FN, precision, recall, and F-measurement are as follows:

TP: The number of accurate data correctly classified into its class by the classifier.

TN: Number of actual data classified into other classes by the classifier.

FP: The number of non-real data classified into its class by the classifier.

FN: Number of non-real data classified into other classes by the classifier.

Precision: The fraction of the number of accurate data classified exactly into its class divided by the total number of data classified in its class as in Eq. (2).

$$TP / (TP + FP) \tag{2}$$

Recall: The fraction of real data correctly classified into its class as in Eq. (3).

$$TP / (TP + FN) \tag{3}$$

F-Measurement: The combination of precision and recall values produces a value called the harmonic mean to ensure that the measure of effectiveness correlates with precision. The F-measure formula is shown in Eq. (4),

$$F - Measurement = 2 * \frac{Precision * Recall}{Precision + Recall}$$

$$= \frac{2TP}{2TP+FP+FN} \tag{4}$$

Table IX shows the confusion matrix table involving the fractional motifs of 'Alam Benda', and the specific motifs of 'Keris'. Part A is a matching selection of respondent number three, representing three expert respondents in Part (A) who agree on the similarity of the specific Motif. When Part B results from a complete evaluation using the formula of precision, recall, and F-measurement.

Next, Table X to Table XIV displays the performance evaluation results of the main motifs 'Flora', 'Fauna', 'Motif', 'Nature', and 'Cosmos' which involves 50 ground truth data of Songket Motifs that have been selected for the continuity of the image retrieval system testing process implemented in the testing and evaluation phase. Table X is the performance evaluation result of the 'Flora' ground truth Motif's image. The ID-Category involved is 004, 019, 036, 001, 012, 047, 031, 003, 022, 048, 033, 034, 032, 008, 021, 007, 025, 010, 009 and 011. Each obtained the result of calculating the F-measurement value between 26.7% to 100%.

TABLE X. RESULTS OF THE EVALUATION OF PERFORMANCE MEASUREMENT OF SONGKET MOTIF'S IMAGES IN THE 'FLORA' CATEGORY

Flora			
ID-Category	***Precision***	***Recall***	***F-Measurement***
004	100	100	100
019	100	100	100
036	100	100	100
001	72.7	100	84.2
012	63.6	100	77.8
047	61.5	100	76.2
031	60	100	75
003	52.2	100	68.6
022	50	100	66.7
048	46.2	100	63.2
033	45.5	100	62.5
034	45.5	100	62.5
032	36.4	100	53.4
008	36.5	100	53.5
021	31.3	100	47.6
007	25	100	40
025	21.9	100	35.9
010	19.2	100	32.3
009	17.3	100	29.5
011	15.4	100	26.7

Table XI shows the performance evaluation results of Songket Motif's images for the 'Fauna' category. Based on Table XI, six actual Songket Motif data are classified in the 'Fauna' category. The six ground truth data involve ID-Category 013, 043, 040, 039, 050, and 042. Meanwhile, the results of the F-measure evaluation are 100%, 92.3%, 92.3%, 89%, 72%, and 35.3%.

TABLE XI. RESULTS OF THE EVALUATION OF PERFORMANCE MEASUREMENT OF SONGKET MOTIF IMAGES IN THE 'FAUNA' CATEGORY

Fauna			
ID-Category	***Precision***	***Recall***	***F-Measurement***
013	100	100	100
043	85.7	100	92.3
040	85.7	100	92.3
039	80	100	89
050	56.3	100	72
042	21.4	100	35.3

Table XII. evaluates the performance measurement of specific Motif images for the 'Motif' category. This category is labeled as 'Motif' because specific Motif images obtained through different sources from [18], which is titled 'Symbolism in Terengganu Melayu songket motifs' and specific Motif in this class, cannot be mapped in any category that was introduced in the writing of the book. Therefore, in Table XII, nine ground truth Songket Motif's data are classified under the 'Motif' category. The nine ground truth data involve ID-Category 014, 015, 024, 029, 023, 026, 028, 030 and 027. Meanwhile, the results of the F-measurement evaluation are 100%, 100%, 75%, 58.1%, 57.1%, 54.5%, 53.3%, 53.3% and 47.6%.

TABLE XII. RESULTS OF THE EVALUATION OF PERFORMANCE MEASUREMENT OF SONGKET MOTIF'S IMAGES IN THE 'MOTIF' CATEGORY

Motif			
ID-Category	***Precision***	***Recall***	***F-Measurement***
014	100	100	100
015	100	100	100
024	60	100	75
029	40.9	100	58.1
023	40	100	57.1
026	37.5	100	54.5
028	36.4	100	53.3
030	36.4	100	53.3
027	31.3	100	47.6

Further, Table XIII shows the performance evaluation results of the ground truth Songket Motifs of the 'Nature' category. Referring to Table XIII, eight ground truth data of specific motifs are classified in the 'Nature' category. The eight ground truth data involve ID-Category 006, 020, 038, 046, 037, 005, 044, and 35. Meanwhile, the results of the F-measurement evaluation are 100%, 100%, 100%, 84.2%, 79.8%, 76.9 %, 63.2%, and 30.8%.

TABLE XIII. RESULTS OF THE EVALUATION OF PERFORMANCE MEASUREMENT OF SONGKET MOTIF'S IMAGES IN THE 'NATURE' CATEGORY

Nature			
ID-Category	*Precision*	*Recall*	*F-Measurement*
006	100	100	100
020	100	100	100
038	100	100	100
046	72.7	100	84.2
037	66.7	100	79.8
005	62.5	100	76.9
044	46.1	100	63.2
035	18.2	100	30.8

Table XIV is the ground truth data of Songket Motif's classified under the 'Cosmos' category. The seven ground truth data are ID-Category 002, 041, 045, 017, 049, 018, and 016. Meanwhile, the evaluation results of the F-measurement for ID-Category are 100%, 94.1%, 84.2%, 70.6%, and 70, respectively. %, 62.5%, and 53.3%.

TABLE XIV. RESULTS OF THE EVALUATION OF PERFORMANCE MEASUREMENT OF SONGKET MOTIF'S IMAGES IN THE 'COSMOS' CATEGORY

Cosmos			
ID-Category	*Precision*	*Recall*	*F-Measurement*
002	100	100	100
041	88.889	100	94.1
045	72.727	100	84.2
017	54.5	100	70.6
049	53.846	100	70
018	45.5	100	62.5
016	36.4	100	53.3

Referring to Table X to Table XIV, there is a low F-measurement value due to the calculation process using the confusion matrix technique; the selection for each category of similar Songket Motif types has the sum of several fractions of different Songket Motif types. For example, 'Daun' and 'Anggur' specific motifs were chosen by respondents as similar but in different categories. This is because the motif has a similar structure.

V. CONCLUSION

Two research objectives were discussed in determining the ground truth data for Songket Motif. The first objective was to identify the ground truth data set involving Activity One, which aimed to obtain two ground truth data sets: training data set and test data set. These data sets involved six categories: ' Flora', 'Fauna', 'Nature', 'Cosmos', 'Food', and 'Calligraphy'. The survey was conducted through a qualitative method involving 15 respondents who classified 413 specific motif images into 56 Songket Motif categories referring to the six prominent motifs.

The second objective was a validation-classification test of ground truth data sets by three experts. The aim was to equate the selection of general respondents with expert respondents to obtain training data sets for testing purposes involving six categories. After rearranging, only 50 ground truth Songket Motif's data were selected referring to five categories: 'Flora', 'Fauna', 'Nature', 'Cosmos', and 'Motif'. The relationship coefficient correlation method was implemented to evaluate the relationship between two data through a statistical evaluation angle.

In addition, precision and recall methods were also used to obtain precision and recall values for each ground truth data that had been selected. The F-measurement method was used to make a single evaluation that was the average value of each ground truth data. In Phase Two, the analysis of the study focused on human observation of the appearance of Songket Motifs.

VI. FUTURE WORK

The limitation of the study of determining ground truth data through human observation is that the detailed geometric characteristics are less effective because every human observation evaluates shape characteristics according to the individual's perception.

Thus, the technology determination technique is also able to help in the process of determining the ground truth data for the image retrieval research. Accordingly, this research can be developed by providing data determination techniques in computer vision.

An Approach to Classifying X-Ray Images of Scoliosis and Spondylolisthesis Based on Fine-Tuned Xception Model

Quy Thanh Lu, Triet Minh Nguyen
Information Technology Department, FPT University, Can Tho, Viet Nam

***Abstract*—The vertebral column is a marvel of biological engineering and it considers a main part of the skeleton in vertebrate animals. In addition, it serves as the central axis of the human body comprising a series of interlocking vertebrae that provide structural support and flexibility. From basic works like bending and twisting to more complex actions such as walking and running, the spine's impact on human life is profound, underscoring its indispensable role in maintaining physical well-being and overall functionality. Moreover, in the hard-working schedule of people in modern life, a bunch of diseases impact on vertebral column such as spondylolisthesis and scoliosis. As a result, numerous researches were provided to take a hand in solving or avoiding these illnesses including machine learning. In this study, transfer learning and fine tuning were used for the classification of X-ray images on vertebrae sickness to avoid complex and wasted time in a medical examination process. The dataset for vertebrae illnesses X-ray images was collected at King Abdullah University Hospital and Jordan University of Science and Technology in Irbid, Jordan. It comprised 338 subjects including: 79 spondylolisthesis, 188 scoliosis, and 71 normal X-ray images. With the customized layers model in Xception that is used for image classification, we received surprisingly high results including validation accuracy, test accuracy, and F1 score in three-class classifications (i.e., spondylolisthesis, scoliosis, and normal) at 99.00%, 97.86%, and 97.86%, respectively. Additionally, two-class detection also received high accuracy values (i.e., 98.86% and 99.57%). Considering various high-performance metrics in the result indicates a robust ability to identify vertebrae diseases using X-ray images. The study found that machine learning significantly raises medical examinations compared to traditional methods, offering a myriad of benefits in terms of accuracy, efficiency, and diagnostic capabilities.**

***Keywords*—Transfer learning; fine tuning; spondylolisthesis; scoliosis; classification; Xception**

I. Introduction

In the busy world, many people deal with back problems like spondylolisthesis and scoliosis. These are issues with the spine that can make daily tasks such as working or studying harder. Spondylolisthesis happens when a vertebra in the spine moves out of place, causing pain in the lower back and sometimes putting pressure on nerves. Scoliosis is when the spine curves sideways in an unusual way. People with these conditions often have jobs that need a lot of physical effort, and sitting or standing for a long time can make things worse. To cope with these spine problems, many people use treatments that don't involve surgery. These include things like physical therapy, finding ways to manage pain, and making changes to the workspace to make it more comfortable. These steps help improve movement, reduce pain, and provide individuals continue contributing productively in their work.

Nevertheless, dealing with spondylolisthesis and scoliosis goes beyond just feeling uncomfortable. Moreover, it can also bring different levels of risk to people working even can be dangerous. If people do not take care of spondylolisthesis, it can lead to long-lasting pain, weak muscles, and even problems with nerves. Scoliosis, with its spine curvature, might cause breathing and heart issues and it affects overall health. In severe cases, surgery might be needed and make life more complicated. Despite these challenges, people should understand the management of their spinal conditions because it is crucial for motor nervous systems. In addition, it can help mitigate the risks associated with spondylolisthesis and scoliosis. This enables individuals to navigate their careers with resilience, adaptability, and a focus on their target.

Spinal diseases are increasing in modern times, especially scoliosis and spondylolisthesis. Despite this, symptoms of scoliosis with back pain are often overlooked by patients. In contrast, if people actively care about their health, we can easily identify the differences. Scoliosis and back pain seem to have specific characteristics in adult pain. For example, its location is often asymmetrical and associated with headaches. Furthermore, it is still unclear whether the intensity and duration of pain between adults with scoliosis and those without scoliosis experience back pain [1]. A lot of data collected in recent years around the world indicates the negative effects of scoliosis. To cite an example, the survey shows a dramatic rise in the average incidence of scoliosis diagnosis, climbing from 107 cases per 100,000 individuals in 2015 to 161 cases per 100,000 in 2022. Presently, approximately 1.2% of children and adolescents in Turkey are affected by scoliosis and the rate in women is 1.45 times higher than in men [2]. Besides, spondylolisthesis is a dangerous illness and it affects teenagers to elders. According to research degenerative lumbar spondylolisthesis affects 3% to 20% of globally and up to 30% of the elderly [3]. Additionally, research has shown that the illnesses are rare in those under 50 years old but they increase significantly with age affecting up to 15% of men and 50% of women aged 66–70 years [4]. This led to, people should pay more attention to their spine health to avoid future troubles.

X-ray images carry a pivotal role in the accurate diagnosis of spinal conditions, particularly in the classification of spondylolisthesis and scoliosis. X-ray images provide a comprehensive view of the spinal structure, enabling healthcare professionals to precisely identify and assess these conditions. However, X-ray imaging also has a bunch of limitations. Traditional methods rely heavily on manual interpretation, leading to the potential for human error and subjective variations in diagnosis. In addressing these challenges, machine learning emerges as a promising solution. By applying the power of artificial intelligence, machine learning algorithms can analyze vast datasets of x-ray images with high speed and accuracy. Nonetheless, it is crucial to acknowledge the limitations within the area of machine learning as well. The algorithms heavily depend on the quality and diversity of the training data, potentially leading to biased results. Furthermore, the interpretability of machine learning models in the medical field remains a challenge. Because of that, we need to improve machine learning models regularly to raise prediction and accuracy.

Artificial intelligence (AI) has come out as a trend in this day and age, particularly in the classification and segmentation of images. The ability of AI algorithms to categorize and organize huge datasets has transformed various industries [5], ranging from healthcare to finance. Machine learning techniques, such as deep learning and neural networks, have a main role in enhancing the accuracy and efficiency of classification tasks. These advancements have enabled AI systems to auto-recognize patterns, make predictions, and classify information with high precision. The integration of AI is also gaining prominence, addressing concerns about complex classification models such as illnesses on X-ray, MRI, and CT in health care [6]. In addition, if AI continues to develop its role will become unique in a new area where intelligent systems play an important role in decision-making processes across diverse domains. The trajectory of AI development in classification showcases its potential. This led to, we decided chose to develop the Xception model to gain high accuracy and solve more errors in X-ray image classification.

In this research, we use deep learning in the classification of images. In more detail, transfer learning was used to enhance performance in a novel task by utilizing knowledge acquired from previous learning experiences in similar tasks. By doing so, the model can capitalize on the generalized knowledge it has acquired, thereby improving its ability to tackle new challenges without starting from scratch [7]. Overall, transfer learning offers a powerful and efficient way to leverage previously acquired expertise, fostering improved performance and generalization across a range of tasks. In addition, fine-tuning is an important next step where the pre-trained model or its components are adjusted and optimized specifically for the new task [8]. This fine-tuning process ensures that the model adapts its learned features to the nuances of the target task, striking a balance between the general knowledge gained and the specifics of the current task. For this reason, we propose a method to use the Xception model in the Keras library in a Convolutional Neural Network (CNN) that uses transfer learning and fine-tuning to classify images. Once trained, our model can classify new images or extract features for use in other applications such as object detection or image segmentation.

The contributions of this paper are as follows:

- Our research gains a high accuracy including validation accuracy, test accuracy, and F1 score in three classes' classifications in spondylolisthesis, scoliosis, and normal spine at 99.00%, 97.86%, and 97.86%, respectively. Moreover, pair-wise classification also achieves a high success up to 99.57%.
- Our study suggests a complete model that is used for vertebrae X-ray image classification including a dataset of scoliosis, spondylolisthesis, and normal vertebrae X-ray images. Thus, an expert can apply it in a simple way to help with the detection and classification of X-ray images.
- We find that Partition Explainer can be used effectively which is an algorithm that uses a hierarchical clustering of the data to recursively partition the input space.
- Our collected X-ray images of subjects with scoliosis and spondylolisthesis, as well as healthy ones, as determined by the specialists in the hospital This dataset is confirmed for the development of a model in deep learning including transfer learning and fine-tuning for the classification of vertebrae and can be applied to training and educating medical students, residents, and experts.

Our study comprises four main sections. Section II illustrates some of the related research that we used for references. Section III is the methodology, this section makes clear in detail all of the methods used in the article. Following that, Section IV will outline the experiments, detailing the methodology employed for conducting and assessing the accuracy of the deep learning model. Finally, we will provide a summary of our article and scrutinize the fundamental domains connected to the study in Section V.

II. Related Work

An occupied working environment nowadays such as spending a lot of time at the working table or taking hours in the library to study. Based on several studies showing that, every year about 523 out of 100,000 teenagers develop scoliosis. This condition was twice as common in females compared to males based on the study population comprising 1782 teenagers from 10 to 18 years old [9]. Consequently, several researches on machine learning have been published for the segmentation and classification of X-ray images. For example, Peiji Chen et al. classified patient spine pictures using ResNet and Faster R-CNN. As a result, the combined use of ResNet convolutional neural network and Faster R-CNN has a stronger classification effect on scoliosis disorders than traditional machine learning approaches, as completely illustrated by the Area Under the Curve value of 90.87% [10]. Moreover, Joddat Fatima et al segmented the spinal column using Mask RCNN in conjunction with the YOLOv5 method for vertebral localization. The suggested method achieves 94.69% final average classification accuracy [11].

Machine learning plays a central role in classifying X-ray images for medical diagnosis. By leveraging algorithms, it can automatically identify patterns indicative of various conditions. This enhances diagnostic accuracy, expedites analysis, and contributes to more efficient and precise healthcare decision-making. Consequently, Shuman Han et al classified patients with moderate scoliosis with an accuracy of 77.9% and severe scoliosis with an accuracy of 93.6% using x-ray pictures of 204 patients with idiopathic scoliosis using the integrated area algorithm method of machine learning [12]. In addition, with a high accuracy of about 90.0%, Wahyu Caesarendra et al. suggest a deep learning architecture for the recognition of spine vertebrae from X-ray images [13]. This architecture automatically evaluates the Cobb angle and assesses for the presence of scoliosis and the severity of the curvature.

Especially in the analysis of X-ray pictures, Convolutional Neural Network (CNN) have completely changed deep learning for image classification. Their capacity is automatically extract hierarchical characteristics from pictures allows for the correct identification of patterns suggestive of different medical problems. CNN is required for improving X-ray image classification in medical diagnostics in terms of accuracy and precision. Furthermore, CNN is a common way to diagnose spondylolisthesis X-ray images in humans. For example, Fatih Varçın et al. used the MobileNet model in Convolutional Neural Network to classify spondylolisthesis or normal and achieved high results with a test accuracy reach of 99% [14]. Moreover, Deepika Saravagi et al. collected 229 X-ray images which include spondylolisthesis and the normal spine (i.e., 156 spondylolisthesis and 143 normal) which were optimized by applying the TFLite model optimization technique. As a result, the model reaches a high accuracy rate including the VGG16 model of 98% and InceptionV3 of 96% [15]. Additionally, Fatih Varçın et al. also AlexNet and GoogleLeNet models to classify the data set consisting of 272 X-ray images. According to experimental results, GoogleLeNet performs marginally better than AlexNet, which has an accuracy of 91.67%, with a 93.87% accuracy rate [16].

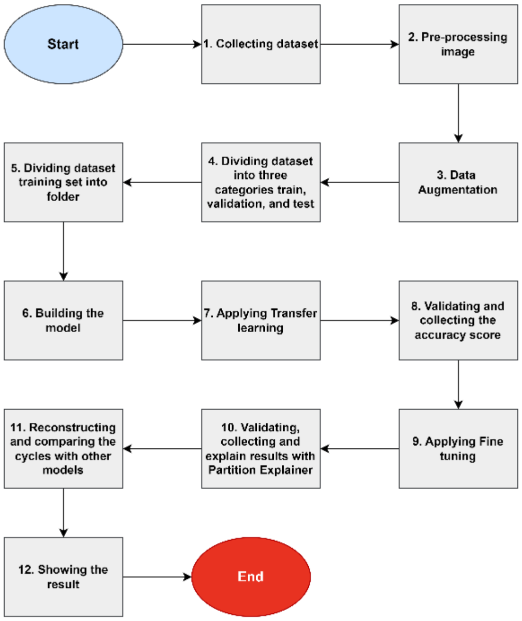
Processing medical images in X-ray images has witnessed significant promotions through the utilization of transfer learning and fine-tuning techniques. Leveraging pre-trained models allows the transfer of knowledge from general domains to medical imaging while fine-tuning tailors the model for specific diagnostic tasks. This approach enhances the efficiency and effectiveness of X-ray image analysis in medical applications. For instance, Mohammad Fraiwan et al. used transfer learning in the DensNet-201 model and reached a mean accuracy and maximum accuracy for spine illness classification were 96.73% and 98.02%, respectively [17]. Furthermore, Using the VGG16 model for feature extraction and CapsNet for disease identification, Deepika Saravagi's experimental results show 98% accuracy [18]. The dataset contains 466 X-ray radiographs, with 186 images showing a spine with spondylolisthesis and 280 images showing a normal spine.

Deep learning models could help handle the growing amount of medical imaging data and offer an early analysis of pictures collected in basic care. When it comes to scoliosis identification, deep learning algorithms provide a faster and more effective solution than manual X-ray investigation. Arslan Amin et al. used a pre-trained EfficientNet model to achieve an accuracy of 86 % on the detection and classification of scoliosis from X-ray images [19]. Besides, Ariana Alejandra Andrews Interiano et al. take a database of medical images from Honduran to transfer learning and fine-tuning in InceptionResNet, MobileNet, and EfficientNet. Hence, their experiment finds a high average accuracy of 98.01% [20]. Furthermore, Dalwinder Singh et al. applied CNN to classify MRI lumbar spine images and used differential spider monkey optimization (SMO) to get the highest classification accuracy of 96% [22]. In conclusion, a bunch of different research has been published in recent times to propose the accuracy in segmentation and classification in medical and help patients avoid a lot of time and money for a long procedure in treatment.

III. Methodology

A. The Research Implementation Procedure

This study proposes a method including 12 steps shown in Fig. 1. The roles of the steps are shown as follows:



Start
1. Collecting dataset
2. Pre-processing image
3. Data Augmentation
4. Dividing dataset into three categories train, validation, and test
5. Dividing dataset training set into folder
6. Building the model
7. Applying Transfer learning
8. Validating and collecting the accuracy score
9. Applying Fine tuning
10. Validating, collecting and explain results with Partition Explainer
11. Reconstructing and comparing the cycles with other models
12. Showing the result
End

Fig. 1. The implementing procedure flowchart.

1) *Collecting dataset:* The dataset about vertebrae illnesses is collected at King Abdullah University Hospital and Jordan University of Science and Technology in Irbid, Jordan. The collection contains X-ray images of two types of spine illness that is spondylolisthesis, and scoliosis. Besides, one class for normal images is provided. This collection provides a valuable resource for medical research.

2) *Pre-processing image:* Standardized input conditions were fixed for CNN models through the use of resizing and normalization. As a result, the outcomes of the results grow.

3) *Data augmentation:* This step is a technique of artificially increasing the dataset by creating modified copies

of a dataset using existing data to apply functions such as rotate, flip, and brightness contrast.

4) Dividing the dataset into three categories train validation and test: The entire X-ray images dataset includes 3500 subjects after increasing in data augmentation by 338 default subjects with random selection used in the phases of training, validation, and testing. An 8-1-1 scale is used to randomly choose the datasets, dividing them into eight halves for training, 1 for validation, and 1 for testing. This ensures a balanced distribution, which is necessary for reliable model creation and assessment.

5) Dividing the training set into folders: spondylolisthesis, scoliosis, and normal spine are divided into many different folders. The first folder is 3-fold including spondylolisthesis, scoliosis, and normal spine. Our goal is to compare the largest folder by displaying the training data in a more precise manner. As a result, the other folder has 2-fold classifications: scoliosis-normal and spondylolisthesis-normal.

6) Building the model: To do experiments, we used transfer learning to a pre-trained model and rebuilt the model based on the CNN architecture prototype. Subsequently, fine-tuning is the process of modifying the weights of the pre-trained model on the particular data of the target job. Consequently, the Xception model produces an outstanding outcome for our training test.

7) Applying transfer learning: In transfer learning, a large dataset was used for leveraging a pre-trained model. This dataset may contain a large amount of labeled data. By using knowledge gained from the source task, transfer learning enhances the performance of the model on the target task, particularly when data for the latter is limited.

8) Validating and collecting the accuracy score: We summarized the training accuracy obtained from the predictions made by the model to evaluate its accuracy after it had finished training. Next, we used the initially divided testing set to assess whether the test was correct.

9) Applying Fine tuning: Fine-tuning was applied to the act of modifying the parameters of a pre-trained neural network and the hyperparameters of a model to improve its performance, often in the last layers. This enables the model to draw on elements learned in a broader context while customizing its knowledge to the specifics of the target task.

10)Validating, collecting and explain results with Partition Explainer: After collecting all the metrics such as validation accuracy, test accuracy, and F1 score. After that, a partition explainer in SHAP was used for a specific algorithm for explaining the output of machine learning models. SHAP is a unified approach to explaining the output of any machine learning model, and it is based on Shapley values from cooperative game theory.

11)Reconstructing and comparing the cycles with other models: After the first phase, we rework and compare it with another model including EfficientNetB3, VGG19, ResNet101, and DenseNet169 to create the final result.

12)Showing the result: Following a comparison, the data will be displayed in the form of tables and graphs to allow for relevant comparisons.

B. Pre-processing Image

In the area of image processing, the pre-processing stage plays a central role in enhancing the efficiency and effectiveness of subsequent tasks, such as machine learning model training. Two fundamental operations within this pre-processing pipeline are image resizing (1) and normalization (2). Image resizing involves transforming the dimensions of an image, commonly to a standardized size, to facilitate uniformity and computational feasibility.

The resizing operation is typically represented by the formula:

$$Resized\ Image = Resize\big(Original\ Image, (224{,}224)\big)\# \quad (1)$$

In Formula , the original image goes through a transformation to conform to a predefined resolution of 224×224 This standard size is often used to ensure consistency across the dataset and compatibility with neural network architectures commonly used in computer vision tasks.

Following resizing, the next critical step is normalization, see Formula (2), a process focused on normalizing the pixel values of the image. Normalization is carried out to ensure that the input data falls within a specific range, which aids in stabilizing the learning process during model training. The normalization operation can be mathematically expressed as:

$$Normalized\ Image = \frac{Resized\ Image - \min(Resized\ Image)}{\max(Resized\ Image) - \min(Resized\ Image)}\# \quad (2)$$

Here Formula (2), the pixel values of the resized image are transformed to a range between 0 and 1 by subtracting the minimum pixel value and dividing by the range between the maximum and minimum pixel values. This normalization to the [0, 1] range is crucial for mitigating issues related to varying scales and ensuring that the model receives consistent input across diverse images.

In summary, the connection of resizing and normalization in image pre-processing not only standardizes the size of input images but also establishes a common pixel value scale.

C. Data Augmentation

Augmenting data is a critical step in improving the robustness and generalization capability of machine learning models, notably in picture classification. One widely used strategy involves applying several changes to the original images, resulting in a diverse set of training samples for the model to learn from.

The first step in Formula (3) is the transpose operation involves swapping the rows and columns of the image matrix. Mathematically, if we have an image represented by a matrix I of dimensions $m \times n$, where m is the number of rows and n is the number of columns, the transpose has denoted as I_{trans} (3)

results in a new matrix with dimensions $n \times m$, it can be expressed as:

$$I_{trans} = I^{T} \# \tag{3}$$

The next step in Formula (4), shift scale rotate is used for translations, scaling, and rotations to the image. The rotated image I_{rot} is obtained by applying a rotation matrix $R(\theta)$ (4) to the original image matrix I:

$$I_{rot} = R(\theta) \cdot I \# \tag{4}$$

Here, the rotation limit is set to 45 degrees ($\theta \leq 45$) with a probability p = 0.45 for each image. This ensures a controlled augmentation process that is both effective and computationally efficient.

The third step , horizontal flip (5) and vertical flip (6) operations involve mirroring the image horizontally and vertically, respectively. By means of mathematics, the horizontal flip $I_{horizontal\_flip}$ (5) is achieved by reversing the order of columns in the original image matrix I, and the vertical flip $I_{\text{vertical\_flip}}$ (6) is achieved by reversing the order of rows:

$$I_{horizontal\_flip} = flip(I, axis = 1) \# \tag{5}$$

$$I_{\text{vertical\_flip}} = flip(I, axis = 0) \# \tag{6}$$

Both operations are applied with a probability of $p = 0.5$ to introduce variability in the orientation of the training samples.

The final step (7) is one operation of random brightness contrast and it can be expressed as a single formula, where the brightness and contrast adjustments are applied to each pixel in the image:

$$I_{bc} = I + r_{brightbess} \times I \times r_{contrast} \# \tag{7}$$

In this formula, I_{bc} (7) represents the image after the combined brightness and contrast adjustments, I is the original image matrix. Moreover, $r\_brightbess$ (7) is a randomly sampled value for brightness adjustment, and $r\_contrast$ (7) is a randomly sampled value for contrast adjustment.

These adjustments are executed with a probability of $p = 0.2$ to ensure controlled variability without excessively distorting the image characteristics. In summary, these augmentation techniques collectively contribute to a more diverse and robust dataset, fostering improved performance and generalization of machine learning models in image classification tasks.

D. Transfer Learning and Fine Tuning of Xception

Transfer learning and fine-tuning are powerful techniques in the area of CNN [22], [23], allowing the utilization of pre-trained models to enhance the performance of a specific task. One noteworthy architecture for such applications is the Xception model, which stands out for its depth and efficient use of parameters. Unlike traditional CNN, Xception uses an extreme version of the inception module, known as the depthwise separable convolution. This technique separates the spatial and channel-wise operations, enabling the model to capture both local and global features effectively.

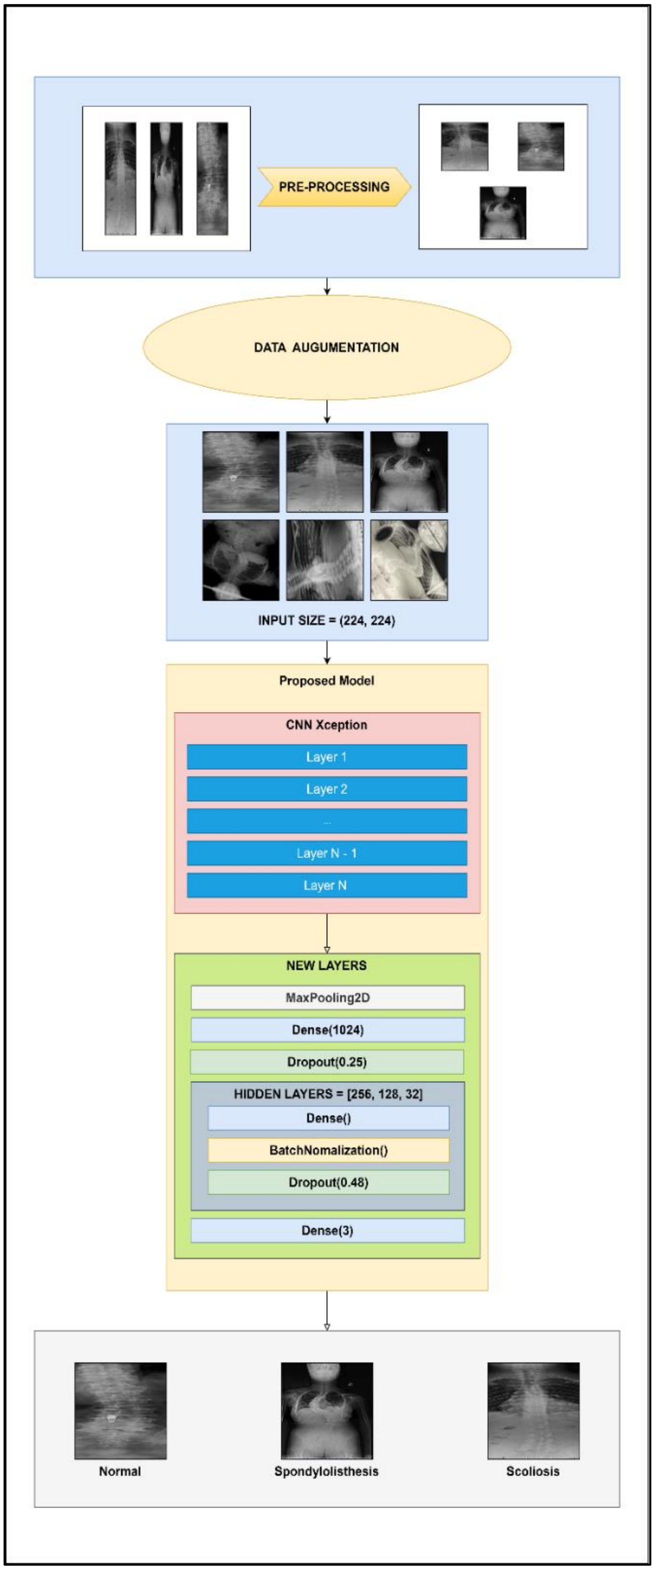


Fig. 2. Procedure of transfer learning and fine-tuning in CNN Xception model and custom layers.

The Xception model, introduced by François Chollet in 2017, is an extension of the Inception architecture. Its key innovation lies in replacing standard convolutions with depthwise separable convolutions, resulting in a more efficient and parameterized model. This architectural shift reduces the risk of overfitting, enhances feature representation, and facilitates faster training convergence. Each depthwise separable convolutional block in Xception consists of a depthwise convolution followed by a pointwise convolution, providing a powerful yet lightweight alternative to conventional convolutional layers.

When it comes to transfer learning and fine-tuning in CNNs, the Xception model proves particularly advantageous. Leveraging the pre-trained weights from a large dataset, such as ImageNet, Xception can be employed as a feature extractor for a diverse range of computer vision tasks. Our study adds more external layers to increase accuracy in Fig. 2 and this process not only saves computational resources but also leverages the rich hierarchical features learned by Xception, enhancing the model's ability to generalize across various visual patterns.

In essence, the seamless integration of the Xception model into CNN architectures and the addition layer described in Fig. 2 for transfer learning and fine-tuning extends the paradigm of leveraging pre-trained models, unlocking the potential for enhanced performance and efficiency in a myriad of computer vision applications.

E. Explain Results with Parition Explainer

In the study, Partition Explainer a method within SHAP (Shapley additive explanations) was chosen as a visual explanation. It serves as a necessary tool in explaining the contributions of individual features in an image-based model. This process is particularly useful for understanding the importance of different aspects within an image and gaining insights into model decision-making. At its core, the Partition Explainer leverages Shapley values, a concept rooted in cooperative game theory, to fairly distribute the model's output among its input features.

In more detail, the Partition Explainer operates by considering all possible subsets of features and calculates the average Shapley value (8) for each feature across these subsets. This careful approach ensures a comprehensive evaluation of the impact of each feature, accounting for their interactions and dependencies. Mathematically, the Shapley value for a feature (φ_i) (8) in a cooperative game is expressed as follows:

$$\varphi_i(f) = \sum_{S\subseteq N\setminus\{i\}} \frac{|S|\,!(|N|-|S|-1)!}{|N|!}\,[f(S\cup\{i\}) - f(S)]\,\# \quad (8)$$

In this Formula (8), N represents the set of all features, S denotes a subset of features excluding 'i', and f(S) signifies the model's output when considering the subset of features 'S'. The Shapley value quantifies the marginal contribution of feature 'i' by averaging across all possible combinations, providing a fair and consistent measure of its impact on the model's output.

In the context of the Partition explainer, this Shapley value calculation is extended to various feature subsets, enabling an expression understanding of how each feature influences the model's predictions.

By using Partition explainer in the final result of Fig. 3, our results gain insights into model behavior, fostering trust and facilitating informed decision-making in the area of machine learning.

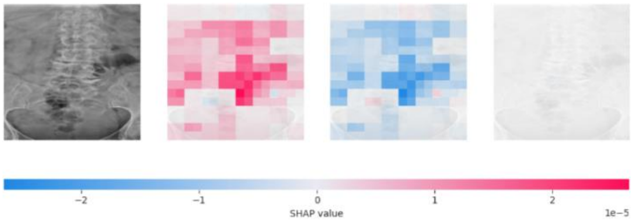

Fig. 3. The final result of classification spondylolisthesis after applying a partition explainer.

IV. Experiments

A. Dataset and Peformance Metrics

For this analysis, a single dataset Fig. 4 was used for training, validation, and testing. A total of 338 pictures, comprising 79 spondylolisthesis, 188 scoliosis, and 71 normal, make up the full X-ray images dataset that was obtained and enhanced by King Abdullah University Hospital and Jordan University of Science and Technology in Irbid, Jordan. The dataset increased to 3500 pictures after data augmentation and it was divided into 8 for training, 1 for validation, and 1 for testing.

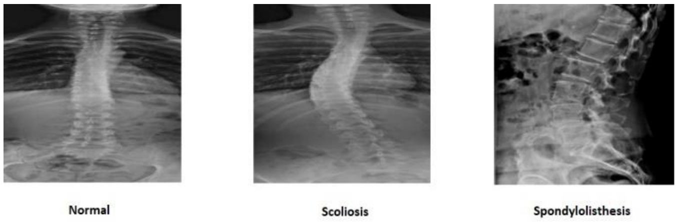

Fig. 4. Dataset about the vertebrae X-ray images.

Additionally, five measures were used to evaluate the model performance: the F1 score, test accuracy, recall, precision, and validation accuracy all have a significant impact on how well a trained model performs and its capacity for generalization.

The F1 score in Formula (9) is the harmonic mean of precision and recall. It balances the trade-off between precision and recall, providing a single value that takes both false positives and false negatives into account. The F1 score is calculated as follows:

$$F1 = \frac{2 \times Precision \times Recall}{Precision + Recall}\,\# \qquad (9)$$

Test accuracy as in Formula (10) measures the proportion of correctly predicted instances over the total number of instances in the test set. It is a common metric for overall classification performance, providing insights into its real-world applicability. This metric is calculated by:

$$Accuracy = \frac{Number\ of\ Correct\ Predictions}{Total\ Number\ of\ Predictions}\,\# \qquad (10)$$

Validation accuracy in Formula (10) is similar to test accuracy, it measures the proportion of correctly predicted instances over the total number of instances in the validation set. It is used during the training process to monitor the model's performance on a separate dataset not used for training.

Precision in Formula (11) talks about the accuracy of positive predictions made by the model, emphasizing minimizing false positives. The precision formula is given by:

$$Precision = \frac{True\ Positives}{True\ Positives + False\ Positives}\# \qquad (11)$$

Recall in equation (12), a metric crucial in scenarios where identifying true positives is paramount, is defined as:

$$Recall = \frac{True\ Positives}{True\ Positives + False\ Negatives}\# \qquad (12)$$

B. Scenario 1: The Results of Classifying X-Ray Images into Two Classes: Scoliosis and Normal Spine

Through customization and training, the scenario aimed to assess how well the pre-trained models performed in correctly diagnosing the X-ray image condition. Furthermore, by using these statistics, we may more easily and intuitively compare the vertebral X-ray images in three classes: normal spine, scoliosis, and spondylolisthesis.

Table I show the performance evaluation metrics for classifying in two classes. The ResNet101 achieved the highest accuracy value in transfer learning over the two statistical measures with a validation accuracy of 99.14%. Test accuracy, precision, and F1 score all reached 98.29%.

On the other hand, in Table II TABLE II. shows our model performed the best after fine-tuning with a validation accuracy of 98.86%. Test accuracy, precision, and F1 score all reached 99.14%. This led to, underscore the effectiveness of customizing the model to the nuances of the target task through fine-tuning. This suggests that while transfer learning provides a strong foundation, fine-tuning allows for a more tailored approach, particularly when dealing with domain-specific nuances.

A sample training and validation progress curve with the loss and accuracy values of our model during fine-tuning is displayed in Fig. 5 and Fig. 6. The graphic shows suitable training and validation sets along with consistent learning behavior. Thus, it shows how our work's fine-tuning accuracy has increased.

TABLE I. THE ACCURACY OF CLASSIFYING X-RAY IMAGES INTO TWO CLASSES: NORMAL SPINE AND SCOLIOSIS IN TRANSFER LEARNING, FOR EACH DEEP LEARNING MODEL

Model	Transfer learning				
	Val acc	Test acc	Precision	Recall	F1
EfficientNetB3	99.00%	97.71%	97.74%	97.71%	97.72%
DenseNet169	88.29%	87.43%	87.24%	87.43%	87.31%
VGG19	94.29%	80.14%	90.86%	90.86%	90.86%
ResNet101	99.14%	98.29%	98.29%	98.29%	98.29%
Our Model	**87.00%**	**83.86%**	**84.33%**	**83.86%**	**84.05%**

TABLE II. THE ACCURACY OF CLASSIFYING X-RAY IMAGES INTO TWO CLASSES: NORMAL SPINE AND SCOLIOSIS IN FINE TUNING, FOR EACH DEEP LEARNING MODEL

Model	Fine tuning				
	Val acc	Test acc	Precision	Recall	F1
EfficientNetB3	97.71%	97.43%	97.42%	97.43%	97.42%
DenseNet169	96.00%	94.00%	93.94%	94.00%	93.95%
VGG19	73.71%	73.57%	54.13%	73.57%	62.37%
ResNet101	79.57%	78.57%	77.09%	78.57%	75.90%
Our Model	**98.86%**	**99.14%**	**99.14%**	**99.14%**	**99.14%**

Fig. 8 and Fig. 9 in this experiment explain training accuracy and training loss in our model for two classes of normal and spondylolisthesis which low test loss (i.e., ~0%).

The outcome confusion matrix is finally displayed in Fig. 10, demonstrating the excellent performance of our model.

D. *Scenario 3: The Results of Classifying X-Ray Images into Three Classes: Spondylolisthesis, Scoliosis, and Normal Spine*

Table V and Table VI illustrate in transfer learning the ResNet101 reaches the highest accuracy value over the three statistical measures with a validation accuracy of 99.00%, test accuracy of 97.71%, and F1 score of 97.72%. However, our model performed achieved the lowest rank in transfer learning with a validation accuracy of 82.00%, test accuracy of 80.71%, and F1 score of 79.97%. The final result is only improved in fine-tuning after our research added more layers and that proves our achievements exactly when our model gets a validation accuracy of 99.00%, test accuracy of 97.86%, and F1 score of 97.86%.

Our Model	**99.00%**	**97.86%**	**97.88%**	**97.86%**	**97.86%**

The training and validation progress curves for a scenario run of the best-performing model are displayed in Fig. 11 and Fig. 12. A model's performance on the training data is measured by training accuracy, which indicates how well the model can learn from the given instances.

The model is guided to reduce mistakes during training by measuring the difference between anticipated and actual values in the training set, which is known as training loss. Validation loss is a crucial metric for assessing the generalization performance of the model, replicating this procedure on an independent dataset.

Fig. 12 shows the sample confusion matrix for three classes of classification. This important step makes it possible for us to see a more intuitive comparison of the results achieved. Fig. 13 illustrates the final result displayed in the SHAP value of Partition Explainer in Fig. 14 which is an excellent way to present visually and provides an overall view for experts and medical teams.

E. Comparison with others State-of-the-art Methods

To examine the accuracy of the proposed model that our article has just given out in the previous section, we compare the accuracy score of the proposed model with other CNN architectures in Table VII, which are EfficientNetB3, DenseNet169, VGG19, and ResNet101.

Our comparison serves as a standardized benchmark, allowing researchers to evaluate the performance of new approaches, identify strengths and weaknesses, and push the boundaries of what is achievable. This process fosters healthy competition, driving innovation and motivating the community to build upon successful methodologies. Assessing generalization across diverse datasets, understanding resource utilization, and uncovering limitations are key outcomes of such comparisons. Moreover, it ensures reproducibility, aligns research with community standards and guides future endeavors toward addressing challenges and improving the overall state of the art in deep learning.

V. CONCLUSION

Our newly developed model showcases commendable performance in classifying vertebrae X-ray images, specifically distinguishing between normal spines, scoliosis, and spondylolisthesis for critical medical applications. The model exhibits a remarkable validation accuracy of 99.00%, a robust test accuracy of 97.86%, and an F1 score of 97.86%, underscoring its efficacy in accurately identifying and categorizing spinal conditions. The success of our model can be attributed to strategic modifications, including the incorporation of dense and dropout layers into the Xception model, coupled with fine-tuning various settings, resulting in a substantial improvement in overall accuracy.

Transfer learning played a pivotal role in our approach, leveraging the pre-trained Xception model as a foundation. This technique involves utilizing knowledge gained from a task-specific source domain, in this case, the general image recognition capabilities of the Xception model, and applying it to our specific task of vertebrae classification. Fine-tuning further refined the model's performance by adjusting its parameters to align with the intricacies of our dataset. This process enhances the model's ability to discern subtle features in X-ray images, enabling more accurate and reliable classification.

While our current model exhibits exceptional results, there are inherent limitations. As with any machine learning model, it is crucial to recognize the boundaries of its capabilities. The accuracy achieved is not absolute, and there may be instances where misclassifications occur. Understanding these limitations is paramount for responsible deployment in medical contexts.

Looking forward, our focus revolves around continuous improvement. By incorporating a wider variety of X-ray images, we aim to ensure the model's adaptability to diverse patient demographics and anatomical variations, thereby fortifying its utility in clinical settings. The incorporation of interpretability tools such as Partition Explainer and SHAP values enhances the model's transparency, providing insights into decision-making processes.

In conclusion, our pursuit is anchored in advancing the classification of vertebrae X-ray images, contributing significantly to the medical field's diagnostic capabilities. As we navigate future developments, we remain dedicated to the responsible and progressive evolution of our model for the betterment of patient care and medical decision-making.

ACKNOWLEDGEMENT

Without expressing our profound gratitude for the inspiration, assistance, advice, and constructive influence provided by Huong Hoang Luong, Hao Van Tran, and Phuc Tan Huynh, this acknowledgment would be inadequate. We consider ourselves lucky to have worked with them, and we are incredibly appreciative of what they have contributed. Your devotion and generosity have been invaluable in making this research possible.

***Abstract*—The University Industrial Corporation (CIU) at the National University of Jaen offers a range of consumable products, encompassing nectar, water, coffee, chocolate, and chocoteja. However, its sales transactions function without a systematic analysis. To address this, the study gathered and analyzed sales data from March to November 2023, aiming to identify and delineate associations among frequently co-purchased products, revealing underlying interdependencies and associations. Employing text mining methodologies, this study preprocessed and analyzed 1542 sales records using the Apriori algorithm, culminating in the extraction of 17 association rules. Among these rules, three standout associations were uncovered: the purchase of chocolate, chocoteja and water suggests a purchase of nectar; chocolate, nectar and water acquisitions correlate with chocoteja purchases; lastly chocolate and nectar purchases are associated with chocoteja acquisitions. These findings provide insights to augment potential production adjustments within the CIU, enabling the leveraging of established associations to boost sales and revenue. Moreover, the identified rules serve as a cornerstone for decision-makers, actionable guidance for stakeholders, enabling the identification of co-purchased products, fostering informed production planning, fine-tuning marketing strategies for customer relationship management (CRM), and enhancing CIU's market competitiveness and profitability.**

Keywords*—*Apriori algorithm; association rules; Customer Relationship Management (CRM); decision making; text mining

I. Introduction

Recent advancements in information technologies have propelled transformative opportunities in several public and private institutions, streamlining services and operational efficiencies for the populations. Consequently, this technological progression has empowered companies to acquire, store, analyze, and interpret vast volumes of data, marking a pivotal shift in the significance of dataset. Thus, the consequential impacts transcend the technological domain, influencing the restructuring of business strategies and marketing activities [1].

Simultaneously, the widespread accessibility of the Internet and the burgeoning domain of e-commerce have accumulated extensive repositories of customer transactional data within websites. Employing sophisticated data mining techniques has enabled the aggregation and analysis of these massive datasets within complex web structures [2], [3]. This revolutionizing data mining movement has significantly shaped the information landscape and society, facilitating the process of transforming large amounts of data into valuable insights and knowledge [4]. The fundamental objective of data mining remains centered on the discovery of high-frequency sets, fostering the extraction of implicit associations, subsequently aiding in informed decision-making. As observed in [5], there exists an intriguing correlation between seemingly unrelated products, such as diapers and beer, co-placement of which resulted in a mutual sales upsurge.

Moreover, text mining, a subset of data mining, involves the transformation of unstructured and semi-structured textual data from vast databases into digital formats for information extraction. Its functional applications span a wide range, including semantic text mining, word feature mining, association rule mining, text clustering analysis, and trend prediction [6].

On the other hand, data mining association algorithms serve as indispensable tools, widely embraced by major tech companies such as Amazon, Google, Netflix, Facebook, and Twitter. These algorithms effectively uncover intricate interrelations among variables within extensive datasets. By extracting interesting correlations, frequencies, and patterns from association rules [7], proving instrumental in predicting relevant elements in subsequent analysis [8].

The array of association rule algorithms spans the Apriori algorithm, Frequent Pattern (FP)-Tree, Equivalence Class Clustering, bottom-up Lattice Traversal (ECLAT) algorithm, and the gray association method. Notably, the Apriori algorithm developed by Agrawal and Srikant [9], stand as the classical paradigm for mining frequent itemset in the domain of association rules analysis [10]. This algorithm operates on a bottom-up search methodology, progressively assembling generated itemset to ensure the identification of frequent item subsets.

The University Industrial Corporation (CIU), an integral component of the Production Center of Goods and Services at the National University of Jaen (UNJ), plays a pivotal role in advancing academic, research, and production endeavors in alignment with the institution's overarching goals. As a part of its unwavering commitment to foster scientific inquiry, promote the UNJ brand, and deliver competitive, high-quality products, the CIU takes the lead in exploring new market opportunities and devising scalable, replicable business strategies.

This study endeavors to perform a comprehensive analysis of product purchases by employing association rules. To accomplish this objective, the research leveraged the renowned Apriori algorithm, which adeptly identifies frequent items within transactional databases. The research dataset, spanning sales from March to November 2023, meticulously focuses on key products offered by the CIU, including chocolate, chocoteja, water, nectar, and coffee.

The organization of this paper is as follows: Section I gives a brief background on data mining. Section II, presents the related research, highlighting key advancements and gaps in the field. Section III outlines the rigorous methodology employed in this study. The core findings, accompanied by in-depth analysis and contextual discussions are conducting in Section IV, and Section V draws the meaningful conclusions, and outlines avenues for future research.

II. State of the Art

The implementation of association rules through the Apriori algorithm has been used in different aspects of knowledge, showcasing its versatility and applicability in diverse fields such as marketing, health sciences, computer science, transportation, education, labor, and mining. In marketing, its utility extended to the dissection of purchase transaction-based product promotions [8], recommending e-commerce links [2], and characterizing e-customer behavior to discern purchase patterns among two customer groups [3]. Noteworthy studies have included analysis of purchased products [11], examination of consumer purchasing patterns [12], encompassing market basket analysis [13], and online shopping through RFMDR model [14]. Furthermore, it found practical application in minimum spanning tree-based shopping [15], and Internet marketing strategies in the cosmetics sales in Taiwan [16].

In the realm of health sciences, association rules' usage facilitated the sifting of potential analgesics from a pool of 311 cases treated with compounded drug prescriptions, extracting data on clinical symptoms and types of Chinese herbs [17]. Notably, it facilitated the development of an automatic diagnostic system for breast cancer detection [18], and the identification of distinguishing factors between dementia patients, and caregivers linked to long-term care services [19]. Furthermore, it revealed a set of frequent items aiding in fetal anomaly detection [20], and uncovered the primary combination of Chinese herbs for Alzheimer's disease treatment within acupuncture practices [21]. Research efforts extended into investigating acupuncture point combinations for the treatment of hemiparesis [22], exploring protein-gene interactions from omics data [23], and identifying links between Polycystic Ovary Syndrome (PCOS), and hormonal imbalances utilizing the DEODORANT model [24]. Associations between attributes characterizing the perfusion patterns in normal subjects illuminated the diagnosis of Alzheimer’s disease [25], unraveling pathogenesis linked to thyroid disease [26], analysis of comorbidity in residents afflicted by chronic diseases [27], and classification of anxiety in palliative patients [28]. Moreover, it delineated specific correlations between individuals with dementia and caregivers based on various dementia subtypes [29].

In the Information Technology (IT) context, a methodological approach has been proposed to advance requirements engineering within the enterprise software domain [30]. Also, significant contributions include outlier cleaning in network measurement data [31], processing voluminous datasets through membrane computing models [32], and developing mobile e-commerce recommender systems for online shopping [33]. Additionally, notable efforts have been directed towards bolstering the security of global cyberspace [34] and enhancing the water wave optimization algorithm [35].

In the transportation sector, specific methodologies have been tailored to scrutinize and process data derived from Iranian railroad accidents [36], and identifying risk factors associated with freight truck accidents [37]. Educational research has surfaced various funding initiatives. Among these are studies analyzing user behavior when requesting texts from the library loans [38], uncovering natural products and anti-migraine nutraceuticals from extensive classical medical literature collections [39], and rule extraction from the scoring records of 2002 computer science students at the Mongolian University of Science and Technology [40].

Within the domain of employment, through investigations were conducted to explore the correlations between employment status, and the employability indicators of maritime graduates [41]. Another study proposed a customer potential value matrix, designed to segment applicants based on their potential value and willingness to engage in purchases, thereby enhancing the scope of customer segmentation strategies [42]. Lastly, in the mining sector, an investigation scrutinized the link between structural deformation and gold mineralization, offering valuable insights into the intricate relationship [43].

This study is based on the pressing need to integrate innovative and technological approaches in the business environment. By using Apriori algorithms and association rules in CIU-Jaen, the complexity of large volumes of data is explored, revealing latent patterns and underlying relationships, that generate opportunities for improvement and facilitating agile decision-making. The exhaustive analysis of the association rules allows deepening the knowledge of the operational dynamics and the behavior of the customers, unveiling behavioral patterns and preferences, facilitating the design of solid strategies to boost growth and ensure sustainable development. The adoption of technological tools and data-based strategies within the business field is a key step to stimulate and promote innovation and adaptability in a competitive and ever-evolving environment.

III. Methodology

The research consists of four crucial steps and is visually represented in Fig. 1:

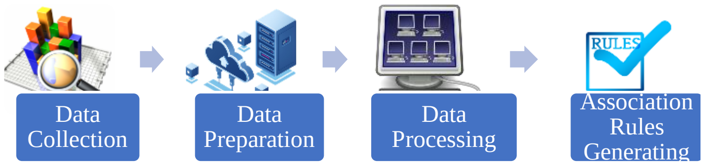

Fig. 1. Apriori algorithm schema.

A. Data Collection

The dataset was meticulously procured a comprehensive dataset from the sales register maintained by the University Industrial Corporation. The corporation employs a manual record-keeping register paper, which includes detailed information about products, such as chocolate, chocoteja, coffee, nectar, and water. The data collection efforts spanned form March to November 2023 as shows in Fig. 2.

Fig. 2. CIU-Jaen data collection.

B. Data Preparation

The acquired data was diligently organized within an Excel worksheet (.xlsx), delineating key attributes such as date, client details, product names, work office, quantity and pricing fields, which is depicted in Fig. 3. Subsequently, a structured flat file (.csv) was generated, employing comma-separated values for seamless data manipulation.

C. Data Processing

Leveraging the powerful capabilities of the R software ecosystem. Specifically, we harnessed the tidyverse, arules, plyr, and arulesviz libraries to transform raw data into meaningful insights, as shown in Fig. 4. The focus of the study was on extracting association rules, a critical step in uncovering hidden patterns and relationships within the dataset. To enhance interpretability, the visualization of the extracted rules was using the arulesviz library. The graphical representations employed three distinct layouts: Fruchterman-Reingold, Kamada-Kawai, and Reingold-Tilford graphs. These layouts elegantly depicted the interconnected nodes corresponding to products like chocolate, chocoteja, nectar, water, and coffee. Arrows extending from antecedent to consequent nodes illustrated the direction of association, emphasizing the sequential relationships. The size of circles positioned at the nexus of these arrows conveyed support values, reflecting the frequency of occurrence for each rule. Additionally, coloration was strategically applied to denote the associated lift values.

Fig. 4. Use R software for data processing.

D. Association Rules Generating

Three criteria were used to identify the relationship: support confidence, and lift.

- Support: It is the percentage of transactions in the database that contain both itemset A and B. The degree of support A ⟹ B in the rule A ⟹ B, is the probability that a given set of itemset contain A and B, which is expressed by the value of probability P(AUB) [44]. A high degree of support indicates that the mining results are consistent and that the provided rules are effective association rules. On the other side, a low degree of support indicates that the data mining results appear only occasionally and the provided rules have little value for the research. Eq. (1) represents the definition of support of the association rule between A and B [45].

$$\text{Support } A \Longrightarrow B = P\,(A \cap B) = \frac{|A \cup B|}{|D|} \qquad (1)$$

- Confidence: It is the percentage of transactions in database D with item set A that also contain item set B [5]. Confidence is calculated using the conditional probability and is expressed relative to the item set support [46] and is represented by Eq. (2):

$$\text{Confidence A} \Longrightarrow \text{B} = \frac{support\ (A \Rightarrow B)}{support\ (A)} = \frac{P(\text{A} \cap \text{B})}{\text{P(A)}} \qquad (2)$$

In Eq. (2), support $(A \Longrightarrow B)$ is the number of transactions containing the itemset A and B, support (A) is the number of transactions containing the itemset A [44].

- Lift: Used to measure the frequency of A and B together, if both sets of items are statistically independent of each other [47]. The calculation is as shown in Eq. (3):

$$\text{Lift A} \Longrightarrow \text{B} = \frac{confidence\ (A \Rightarrow B)}{support\ (A)} = \frac{P(\text{A} \cap \text{B})}{\text{P(A)P(B)}} \qquad (3)$$

The lift of the rule A ⟹ B shows how much the probability of B will increase, if A occurs [48]. There are three cases:

- When lift $(A \Longrightarrow B) > 1$, then there is a positive interdependence between the antecedent and consequent; so, the rule is considered valuable.
- When lift $(A \Longrightarrow B) < 1$, then there is a negative interdependence between the antecedent and consequent.
- When $(A \Longrightarrow B) = 1$, then A and B are independent and there is no correlation between them.

Therefore, the higher the measure of lift, the higher the interest of the generated rules will be. So, with the help of this measure, it will classify the rules that meet the minimum thresholds of support and confidence.

IV. Result Analysis and Discussions

The extracted association rules, meticulously presented in Table I, offer profound insights into the intricate relationships and patterns inherent in the consumer transactions within the dataset. Simultaneously, the graphical representation in Fig. 5, vividly illustrates the frequency distribution of the sold products. Upon discerning the bar chart, a discernible hierarchy in product popularity emerges. Foremost among the products is nectar, indisputably leading in sales volume. Subsequently, chocoteja claims the second position, closely followed by water in third. However, it is imperative to note that, coffee and chocolate, manifest a comparatively lower acceptance rate among consumers.

This analysis not only informs products positioning within the market, but also lays the foundation for strategic decision-making, offering a profound understanding of consumer preferences and market dynamics. The identification of less favored products underscores potential areas for marketing enhancement, contributing to an informed approach for maximizing sales and overall business efficacy.

The outcomes showed in Table I illustrated 17 association rules, each distinguished by a pivotal support attribute, signifying the frequency of rule occurrence within the dataset. It's important to state that, a higher threshold correlates with an augmented frequency of rule manifestation. For instance, the acquisition of chocoteja and nectar frequently coincides with chocoteja, and vice versa.

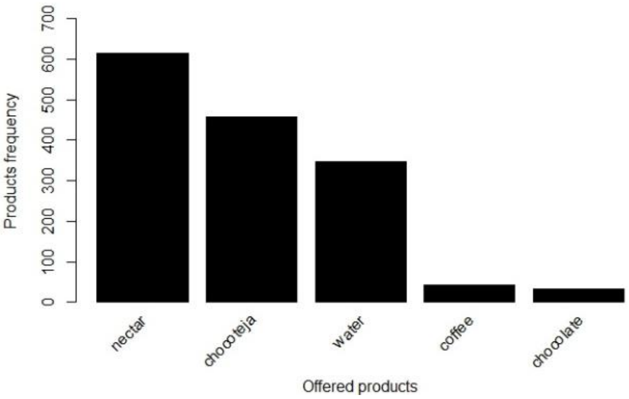

Fig. 5. Bar chart of best-selling products.

TABLE. I ASSOCIATION RULES OBTAINED

Nº	Association rules	Support	Confidence	Lift	Leverage
1	{chocolate} => {chocoteja}	0.0181	0.6563	1.6593	0.0072
2	{chocolate} => {nectar}	0.0173	0.6250	1.1787	0.0026
3	{coffee} => {chocoteja}	0.0225	0.6190	1.5652	0.0081
4	{coffee} => {nectar}	0.0268	0.7381	1.3920	0.0075
5	{chocolate, water} => {chocoteja}	0.0121	0.8235	2.0822	0.0063
6	{chocolate, chocoteja} => {water}	0.0121	0.6667	2.2184	0.0066
7	{chocolate, water} => {nectar}	0.0130	0.8824	1.6641	0.0052
8	{chocolate, nectar} => {water}	0.0130	0.7500	2.4957	0.0078
9	{chocolate, chocoteja} => {nectar}	0.0155	0.8571	1.6166	0.0059
10	{chocolate, nectar} => {chocoteja}	0.0155	0.9000	2.2755	0.0087
11	{coffee, water} => {nectar}	0.0199	0.9200	1.7351	0.0084
12	{coffee, nectar} => {water}	0.0199	0.7419	2.4689	0.0118
13	{chocoteja, water} => {nectar}	0.0484	0.6154	1.1606	0.0067
14	{chocolate, chocoteja, water} => {nectar}	0.0121	1.0000	1.8860	0.0057
15	{chocolate, nectar, water} => {chocoteja}	0.0121	0.9333	2.3598	0.0070
16	{chocolate, chocoteja, nectar} => {water}	0.0121	0.7778	2.5881	0.0074
17	{chocoteja, coffee, water} => {nectar}	0.0121	0.9333	1.7603	0.0052

Table I comprehensively details 17 rules scrutinized with 1542 purchase records involving five different products. Each entry includes a robust rule alongside its corresponding metrics, including support, confidence, lift and leverage. Although the vast dataset and modest support might diminish the impact on confidence verification, three strong rules, considering the aforementioned parameters, warrant attention:

- Rule 14: {chocolate, chocoteja, water} ⇒{nectar}
- Rule 15: {chocolate, nectar, water} ⇒{chocoteja}
- Rule 10: {chocolate, nectar} ⇒{chocoteja}

Examining rule 14, the support stands at 1.21%, confidence at 100%, lift at 1.886, and leverage at 0.00557. These results have a perfect confidence, indicating that whenever chocolate, chocoteja, and water are present, nectar is also present. The high lift value; suggest a strong association between the items, making it a significant rule.

It is the percentage of transactions in the database that contain both itemset A and B. The degree Rule 15, with a support of 1.21%, confidence of 93.33%, lift of 2.3598, and leverage of 0.007, indicating that when chocolate, nectar, and water are present, there is a strong likelihood of chocoteja being present. The lift of 2.3598 suggests a significant association.

Lastly, rule 10 boasting 1.55% support, 90% confidence, 0.0087 leverage, and 2.2755 lift. The high confidence and lift make this rule significant. It indicates a strong association between chocolate and nectar leading to the presence of chocoteja. These selected rules are not only supported by high confidence but also exhibit substantial lift, indicating that the items involved are more likely to be purchased together than if they were chosen randomly. Leverage provides additional insights into the strength of the association, and in these cases, it complements the high confidence and lift values.

The Fig. 6 displays a grouped matrix for 17 rules, where rows represent the RHS (Right Hand Side), columns represent the LHS (Left Hand Side) items, and cells convey information about the strength of association between these elements. Colors denote the lift of products, while size represents the support between them. This graphical representation enhances the comprehension of association relationships between LHS and RHS elements based on metrics such as support and lift. Such a visual approach aids in identifying patterns and interpreting association rules within the context of CIU product purchases.

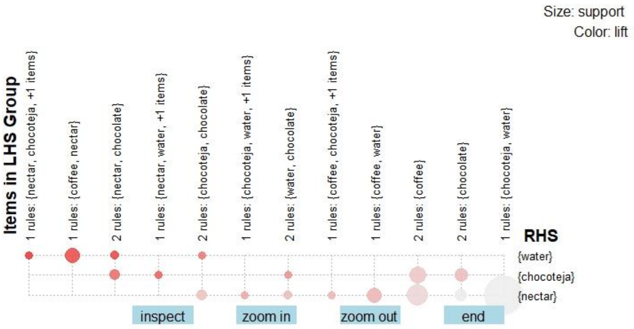

Fig. 6. Grouped matrix for 17 rules.

In the Fig. 7 shown below, there is a visual representation of the association rules extracted through the Apriori algorithm. Specifically, the use of the “htmlwidget” engine enables an interactive experience, allowing users to dynamically explore and analyze the generated rules. For instance, by clicking on a node or edge, users can access detailed information about the rule, including metrics such as support, confidence, and lift. This visualization proves valuable in comprehending purchase patterns and relationships among products, leading to meaningful applications in marketing strategies and business decision-making.

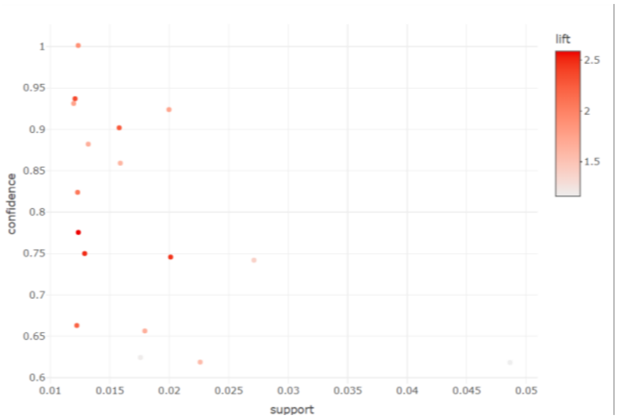

Fig. 7. Scatter plot for 17 association rules.

Analysis of Association Rules

Fig. 8, 9 and 10 depict the association rules, particularly highlighting the rule "chocolate, chocoteja, water ⟹ nectar”, showcasing a modest support but a notably high confidence value. Similar observations are made for the rules "chocolate, nectar, water ⟹ chocoteja” and "chocolate, nectar ⟹ chocoteja”. The graphical and Table II representations affirm the consistency and interrelations of these rules, with variations attributed to the arrangement elements.

The application of the Fruchterman-Reingold (FR) algorithm, grounded in particle physics principles, is evident in Fig 8. Guided by the notions that connected nodes should be proximate, and others should be proximate, and others should maintain a suitable distance [49]. The FR method considers a graph as a collection of vertices connected by edges with two types of forces acting on the vertices. The graph is generated with 500 iterations and an initial temperature parameter of 4.69.

For the creation of two-dimensional graphs, the Kamada-Kawai (KK) method that conceptualizes a graph as a system of spring, was employed [50]. Fig. 9 illustrates the KK algorithm with 1100 iterations and a constant vertex attraction parameter set to 22. In the KK algorithm, the placement of nodes ensures that their visual distance corresponds proportionally to their plotted distance.

TABLE. II STRONG ASSOCIATION RULES OBTAINED

Nº	Association rules	Support	Confidence	Lift	Leverage
1	{chocolate, chocoteja, water} => {nectar}	0.0121	1.0000	1.8860	0.0057
2	{chocolate, nectar, water} => {chocoteja}	0.0121	0.9333	2.3598	0.0070
3	{chocolate, nectar} => {chocoteja}	0.0155	0.9000	2.2755	0.0087

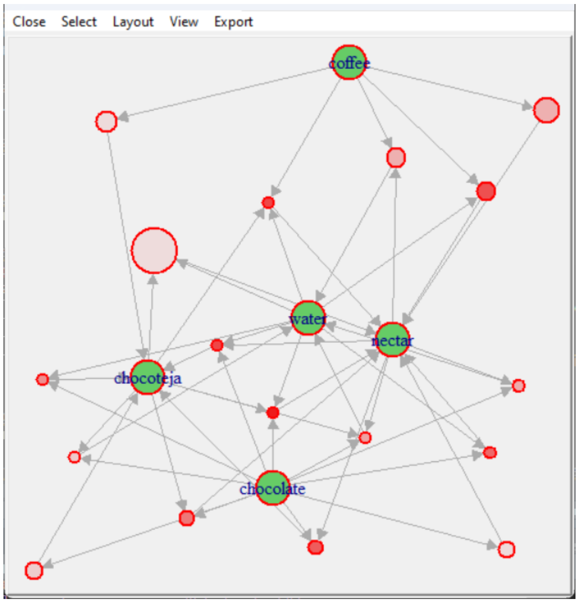

Fig. 8. Graph of Fruchterman-Reingold.

Finally, the Reingold-Tilford algorithm, developed by John Reingold and Jhon Tilford, is instrumental in arranging tree structures to optimize readability. This algorithm assigns coordinates to each tree node, aligning sibling nodes horizontally and positioning child nodes below parent nodes, fostering a visually comprehensible representation of hierarchical data [51]. Fig. 10 demonstrates the application of this algorithm, configured with 1 as the root vertex.

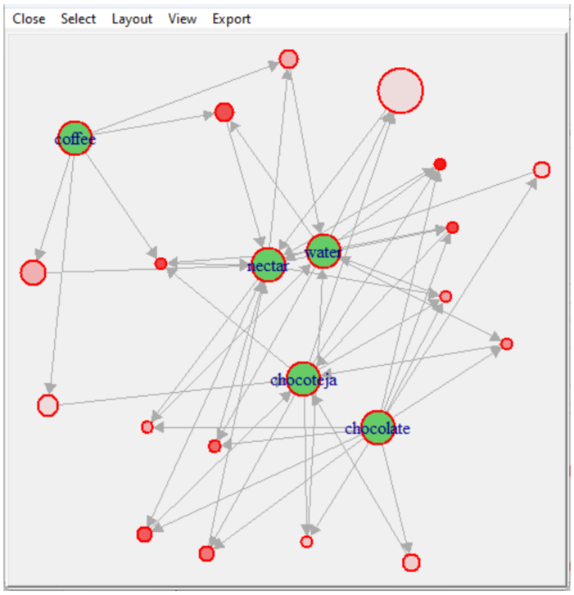

Fig. 9. Graph of Kamada-Kawai.

In Fig. 11, the 17 rules obtained are presented using a visual approach, which provides a graphic and comprehensible representation of the relationships among products. This is essential for interpreting purchase patterns and making strategic decisions in the business and marketing domains. The ability to interactively explore the rules will enable users to gather detailed information about the discovered associations, thereby contributing to a deeper understanding of consumer behavior. In summary, the graphical representations affirm the robustness of the association rules, offering insights into their relationships and highlighting the applicability of diverse algorithms for visualizing these intricate patterns with the dataset. These findings lay a foundation for nuanced interpretations and strategic decision-making.

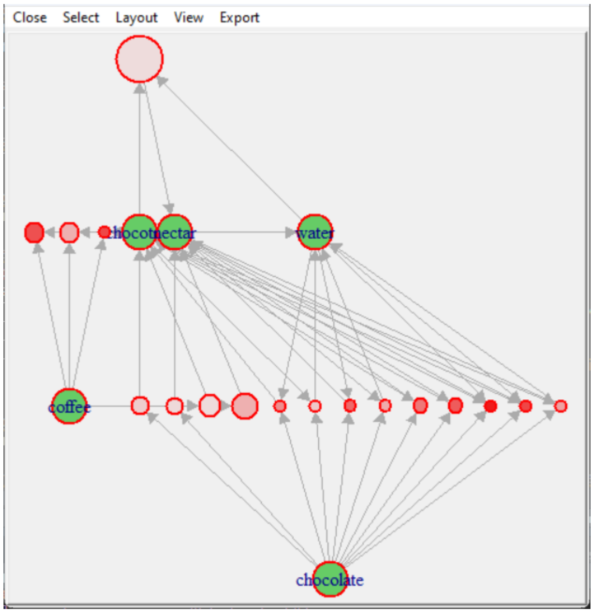

Fig. 10. Graph of Reingold-Tilford.

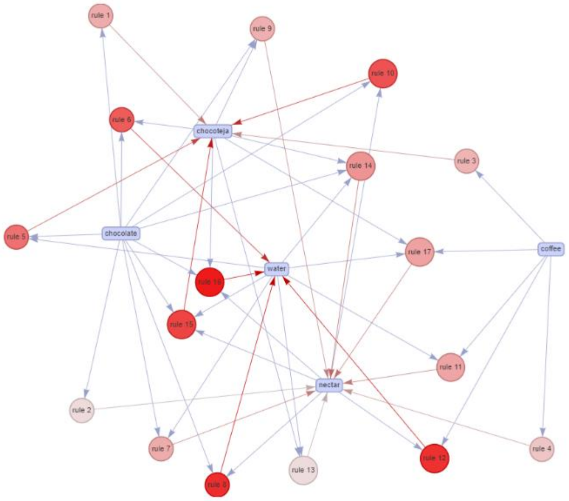

Fig. 11. Graph HTML widget.

In the context of the study, a pivotal challenge confronting marketer lies in augmenting transaction volumes among customers engaged in limited product acquisitions-typically one, two, or three items, a prevalent scenario at CIU-Jaen. Tackling this challenge necessitates the deployment of strategic initiatives, such as flash, strategically amalgamating product displays and promotional information to stimulate impulsive purchases. The subsequent exposition of sales patterns concerning nectar, water, coffee, chocolate and chocoteja, coupled with the discernment of robust association rules, furnishes a valuable foundation for crafting and executing such targeted strategies.

Existing research underscores the affirmative response of customers to well-crafted sales campaigns, particularly in Jaen, a commercial province, where such endeavors hold promising potential for customers attraction and retention. This case study, rooted in the CIU-UNJ market, injects a distinctive dimension into the scholarly discourse by acknowledging and integrating the unique economic and market dynamics inherent to the province of Jaen. Notably, transactions involving three or four products dominated the observe timeframe, a noteworthy insight considering potential marketing budget constraints encountered by institutions within the Jaen market. Despite these constrains, the analysis equips senior management and marketing leaders with the tools to proffer nuanced, tailor-made offering to their customers. Expanding on this point, the identification of frequently co-purchased product combinations empowers companies not only to optimize the physical placement of products within the store but also to devise targeted marketing strategies and product bundles capable of propelling sales.

Nevertheless, it is imperative to acknowledge the constraints imposed by the dataset size and the modest transaction volume averages. Transactions predominantly featuring one or two products limit the scope of the analysis. To enhance the robustness of future studies, it is recommended to use a larger database and the extension of the study duration. This methodological refinement aligns with the pursuit of more objective outcomes, facilitating longitudinal analyses that enable the evaluation of the enduring impacts of strategic marketing decisions on transactional volume and value.

V. Conclusion

This study represents a significant advancement in understanding customer transaction patterns through the application of the Apriori algorithm at CIU-Jaen. By uncovering valuable insights into product associations, the findings inform targeted marketing strategies, discount planning, and direct marketing campaigns, while seamlessly integrating with customer loyalty programs. This holistic approach, embedded within a comprehensive customer relationship management system, enhances the precision and efficacy of marketing initiatives, thereby offering a nuanced understanding of consumer behavior and fostering sustained business growth.

In a broader context, this research offers a nuanced understanding of consumer behavior in the unique market landscape of CIU-Jaen. The association rule identified, based on real transactional data, transcends conventional marketing paradigms, serving as a valuable guide for navigating product placements, promotional efforts, and customer relationship management strategies. As industries grapple with evolving consumer preferences, this study furnishes timely and insightful contributions as a valuable toolset available for strategic decision-making in the domain of marketing and business development.

Looking ahead, future research endeavors could build upon our findings by exploring additional data sources, such as customer feedback and demographic information, to further refine our understanding of consumer behavior. Additionally, investigating the scalability and adaptability of the Apriori algorithm in diverse market contexts could offer valuable insights for practitioners seeking to leverage data-driven approaches in their marketing strategies. Ultimately, by continuously refining our methodologies and insights, we can better anticipate and respond to the evolving dynamics of consumer preferences, driving innovation and growth in the field of marketing and business development.

Acknowledgment

This study was adopted by data reporting sales provided by the University Industrial Corporation. Besides, our sincere gratitude extends to the National University of Jaen for their invaluable support and collaboration throughout the research. Also, we express profound appreciation to every professional whose contributions enriched the depth and breadth of this study.

Automated Detection of Autism Spectrum Disorder Symptoms using Text Mining and Machine Learning for Early Diagnosis

Mihaela Chistol*, Mirela Danubianu
Faculty of Electrical Engineering and Computer Science, Ştefan cel Mare University, Suceava, Romania

Abstract—**Autism spectrum disorder (ASD) is a neurological condition whose etiology is still insufficiently understood. The heterogeneity of manifestations makes the diagnosis process difficult. Thus, many children are diagnosed too late, which leads to the loss of precious time that can be used for therapy. A viable solution could be to equip medical staff with modern technologies to detect autism in its early stages. The objective of this research was to investigate, through empirical means, how text mining and machine learning (ML) algorithms can aid in the early ASD diagnosis by identifying patterns and ASD symptoms in text data regarding children's behavior that concerned parents provided. The research involved the design of an innovative technical solution based on text mining for the identification of ASD symptoms in unstructured text data describing children's behavior and the practical implementation of the solution using Rapid Miner. The dataset was created through a controlled experiment with 44 participants, parents of children diagnosed with ASD, who answered questions about their children's (35 boys and 9 girls) behavior. Analysis of the performance of models trained with ML algorithms: Naïve Bayes, K-Nearest Neighbors, Deep Learning and Random Forest revealed that the K-Nearest Neighbors classifier outperformed the other methods, achieving the highest accuracy of 78.69%. Results obtained using text mining and ML demonstrated the feasibility of using parents' narratives to develop predictive models for autism symptoms detection. The achieved accuracy highlights the potential of text mining as an autonomous and time- and cost-effective method for early identification of ASD in children.**

Keywords—Text mining; machine learning; artificial intelligence; assistive technologies; Autism Spectrum Disorder; early diagnosis; screening

I. Introduction

A. Text Mining

Advances in the information technology (IT) industry provide efficient methods for data creation, storage and processing. Global data consumption is growing at an exponential rate, and projections indicate that by 2025, the volume of data used will exceed 180 zettabytes [1]. Today, data means much more than numbers and letters—it includes images, sounds and text. King's research findings [2] indicate that 80% of the world's data is in unstructured format. This statistic highlights the importance of unstructured data processing techniques such as text mining. Text mining is a contemporary concept of computer science that contributes to solving the information crisis by combining data mining (DM), machine learning (ML) and natural language processing (NLP) techniques.

B. Medical Text Mining

The scientific community explored new horizons for the applicability of text mining and understood the utility of this technology in the medical field [3], [4], [5]. The healthcare industry collects enormous amounts of unstructured text information such as patient data, clinical test results, doctor observations and notes. These records, which are typically stored in electronic format, have the potential to enhance the standard of medical treatment by supporting physicians in making well-informed decisions. However, most of this valuable information is unused. One reason for ignoring this data is the lack of appropriate technological tools for processing the large volume of unstructured data. Contemporary advances in IT have contributed to the development of artificial intelligence (AI) algorithms that have facilitated the growth of medical text mining. The term "medical text mining" refers to methods of processing and extracting knowledge from medical text. This area of research combines ideas and techniques from linguistics and health informatics (HI). As emphasized by Dalianis [6], who analyzed the applicability of text mining in the clinical field, text mining is used for NLP, classification, clustering, information extraction (IE) and information retrieval (IR).

C. Autism Spectrum Disorder

Autism Spectrum Disorder (ASD) is defined as a complex neurological and developmental disease by the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) that is characterized by difficulties with communication and social interaction [7]. The ASD prevalence is estimated at 1 in 100 children according to World Health Organization (WHO) [8]. The high incidence raises a wake-up call to improve the capacity of medical institutions to treat ASD and other developmental disabilities.

D. Challenges of Early Autism Spectrum Disorder Diagnosis

Early autism diagnosis and therapeutic interventions have been reported to be important for achieving satisfactory clinical progress [9]. Conventional approaches to ASD diagnosis involve a comprehensive clinical evaluation and developmental screening with standardized tests, and interviews with psychologists and medical specialists such as Autism Diagnostic Observation Schedule (ADOS) [10], Autism Diagnostic Interview Revised (ADI-R) [11] and Diagnostic

*Corresponding Author.

Interview for Social and Communication Disorder (DISCO) [12]. However, due to the heterogeneity of ASD, the presence of false positive results remains a challenge for clinicians [13]. In addition, clinical examinations are time-consuming and negatively influence the patient behavior because patient is not in the home environment and is surrounded by unfamiliar people and these stimuli may be triggers for crisis-value behaviors.

E. Automated Detection of Autism Spectrum Disorder Symptoms Using Text Mining and Machine Learning

New technologies can help doctors and families who suspect their child may have autism in screening and diagnosis. Text mining provides capabilities to analyze large amounts of unstructured text data related to a child's behavior, development, and interaction.

The present research study findings revealed that text processing algorithms can recognize ASD-specific symptoms in semi-structured screening texts and unstructured texts such as parents' narratives. This scalability holds substantial advantages for doctors, providing them with tools based on text mining technology that can analyze data and flag risk factors or markers of autism. By integrating text mining into diagnostic procedures, healthcare professionals and parents can benefit from early detection of autism symptoms, accurate analysis, and improved support for children with ASD. From this perspective, the contributions of our study are:

- The design of an innovative technical solution based on text mining to identify ASD symptoms in unstructured text data that describes the child's behavior and the practical implementation of the solution that involved a controlled experiment with 44 participants, parents of children diagnosed with ASD.
- Empirical analysis of the accuracy of models trained to identify ASD symptoms in unstructured text data with Naïve Bayes, K-Nearest Neighbors, Deep Learning, Radom Forest ML algorithms.
- Outline of implications for employing text mining in the design and development of healthcare technologies for ASD diagnosis.

F. Paper Structure

The structure of this paper is organized to provide a comprehensive understanding of the design and implementation of the automated ASD symptom detection process using text mining and ML. In the introduction section, we outline the context and highlight the importance of research for early autism diagnosis. Section II describes the methodology used to conduct the research and collect information from parents of children with ASD. Section III brings an in-depth analysis of the results obtained, emphasizing the advantages and limitations. Finally in Section IV, we present the conclusions and outline directions for future research.

II. Materials and Methods

A. Research Questions

The present study's aim was to investigate, through empirical means, how text mining and machine learning algorithms can aid in the early ASD diagnosis by detecting patterns and ASD symptoms in text data regarding children's behavior that concerned parents provided. To address the topic of interest two research questions were formulated and are presented in Table I.

TABLE I. Research Questions

ID	*Research Question (RQ)*
RQ_1	Can text mining be used for detection of ASD symptoms in unstructured text data describing children's behavior?
RQ_2	What are the empirical results of applying text mining and ML algorithms in terms of accuracy in correctly detecting ASD symptoms?

B. Research Participants

The research of Okoye et al. [14] emphasizes the importance of screening in early childhood, between the ages of 18 and 24 months, to achieve positive results in the therapeutic recovery process. Therefore, the premature age of the children and the reduced reading and writing abilities, at this stage of life, determined the involvement of adults in the experiment. 44 parents of children diagnosed with ASD voluntarily participated in the experiment, of which 27 came from the urban environment and 17 from the rural environment, as represented in Fig. 1.

Autism is not equally distributed between genders, with a male-to-female ratio of 4:1 [15]. Approximately the same gender ratio is also encountered in the children participating in the experiment, 35 boys and 9 girls, as indicated in Fig. 2. It is important to understand the gender distribution because symptoms in girls may manifest differently than in boys, thus leading to under diagnosis of ASD in girls [16].

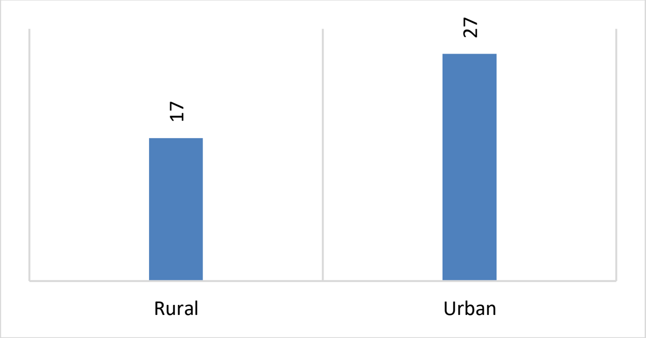

Fig. 1. The distribution of participants according to their residence.

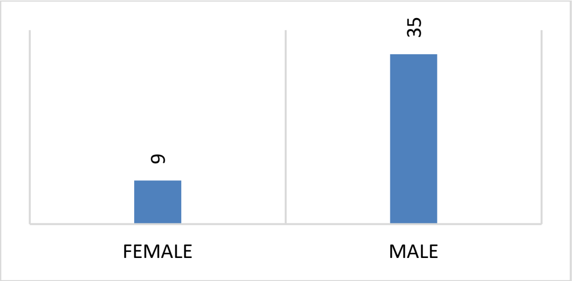

Fig. 2. The gender distribution of children with ASD participating in the experiment.

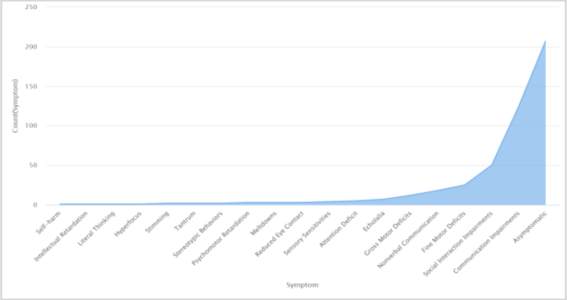

Fig. 3. The quantitative distribution of labels in the dataset.

C. Research Methodology

Following ethics committee approval, participants were invited to answer questions about their child's behavior using the web-based version of Google Forms as instrument. Questions were formulated based on the ASD diagnostic criteria described in DSM-5 [17]. The raw data collected from the participants was analyzed and labeled. The labeling scheme contains 19 labels of which 18 labels represent symptoms specific to autism and one special label "Asymptomatic" which indicates the absence of ASD symptoms. Fig. 3 highlights the quantitative distribution of labels in the dataset. It is noted that the label "Asymptomatic" is the most frequently encountered. This tendency is explained by the fact that the ASD symptom was labeled only in situations where the answer provided by the parent was sufficiently detailed and descriptive to identify that manifestation.

D. Architecture of Technical Solution for Automated Detection of Autism Spectrum Disorder Symptoms using Text Mining and Machine Learning

Diagnosing ASD is a difficult task because the etiology and factors that cause autism are unknown. In addition, the large spectrum of symptoms and the lack of an accurate medical test, such as a blood test, complicate the diagnosis process. Fig. 4 illustrates the conventional diagnosis process, which involves the human factor, represented by the doctor. The doctor analyzes patient biological parameters and applies screening tests and psychological strategies to identify ASD symptoms. The research carried out by Akinnusotu et al. [18] indicate that demanding work conditions affect the psychological state of medical personnel, having an impact on the diagnoses and the effectiveness of recommended treatments. Augmentation of medical workers with modern technologies can be a viable solution in combating burnout. Fig. 5 shows the automated ASD diagnosis process that eliminates the human factor and introduces text mining and ML algorithms to discover autism symptoms in patient data.

The architecture of technical solution for automated ASD symptoms detection in unstructured text data involves complex stages to extract relevant information and build a model capable of recognizing symptoms associated with autism. The stage is inspired by knowledge discovery in text (KDT), a documented research methodology. Fig. 6 present the technical solution implemented using RapidMiner Studio 10.2.

1) Data preprocessing: The data preprocessing is an essential stage in the identification process of ASD symptoms and requires collaboration with qualified medical professionals to draw conclusions about the health status of the participants. These conclusions should be reflected in the labels associated with the text data.

In this stage, records from the dataset that are incomplete and do not provide qualitative information must be removed.

2) Model training: The data preprocessed in the previous phase should be used to train a machine learning model capable of recognizing the ASD symptoms in text data describing the behavior of the child whose parent's suspect autism.

3) Model testing: The model testing stage consists of providing a test dataset as input to the trained model and calculating the performance indicators.

4) Results analysis: The results analysis consists in evaluating the performance of the trained model using the metrics computed in the previous stage, such as accuracy and classification error. Depending on the evaluation results, the model parameters can be adjusted and new machine learning algorithms can be explored.

The automated process of ASD symptoms detection in unstructured text data is empirical and needs to be refined iteratively by experimenting with feature representation, adjusting preprocessing steps and applied machine learning algorithms.

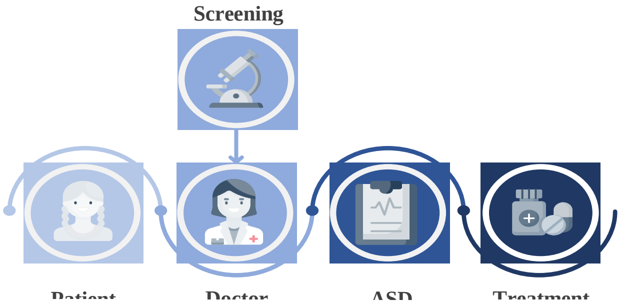

Fig. 4. Conventional ASD diagnosis process.

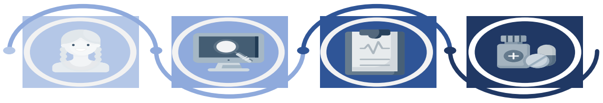

Fig. 5. Automated ASD diagnosis process.

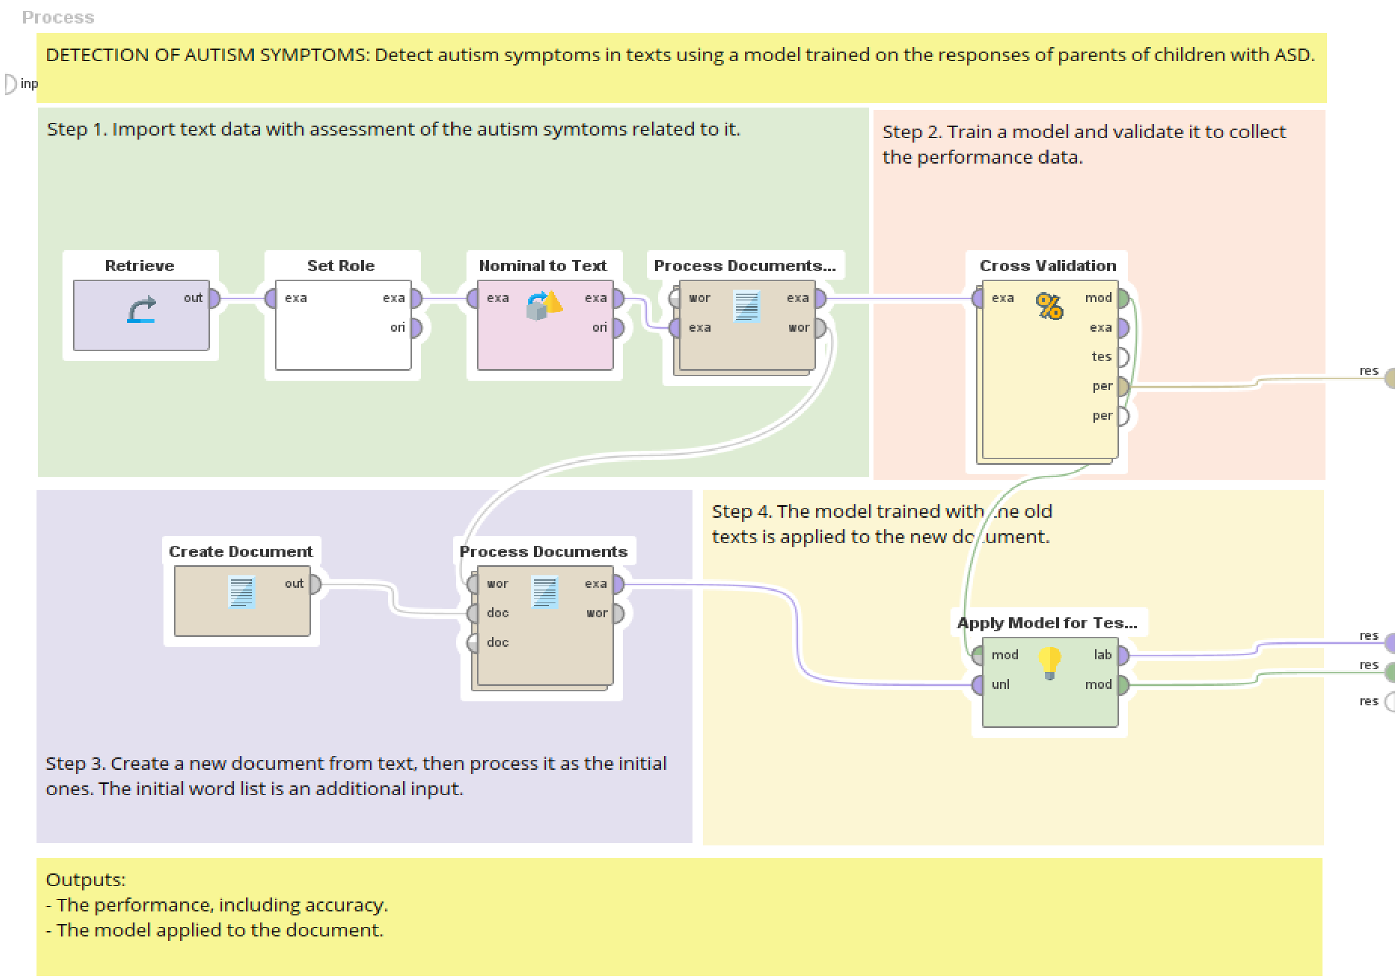


DETECTION OF AUTISM SYMPTOMS: Detect autism symptoms in texts using a model trained on the responses of parents of children with ASD.

Step 1. Import text data with assessment of the autism symtoms related to it.

Step 2. Train a model and validate it to collect the performance data.

Step 3. Create a new document from text, then process it as the initial ones. The initial word list is an additional input.

Step 4. The model trained with the old texts is applied to the new document.

Outputs:
- The performance, including accuracy.
- The model applied to the document.

Fig. 6. Automated ASD symptoms detection process.

E. Text Mining

In text mining, the most influential step is text preprocessing, as it prepares the data for mining. Text preprocessing involves cleaning and transforming raw text data into a suitable format for analysis. In the present context, the Text Processing package was used to preprocess the dataset, with a focus on removing words from parents' responses to the questions that did not make a significant contribution to meaning. This approach aimed not only to improve the quality of the extracted information, but also to reduce the size of the vocabulary, thus contributing to the efficient management of the computational complexity of the dataset. Several methods were applied during text preprocessing: capitalization, tokenization, filter stopwords, stemming, n-Grams and term weighting.

1) Capitalization: Bringing all words to a standardized form, such as converting all letters to uppercase or lowercase, to ensure consistency in textual analysis. Capitalization helps reduce the amount of distinct information that ML algorithms have to process. In ADS symptoms detection process the text data was converted a to lowercase (see Fig. 7).

Example

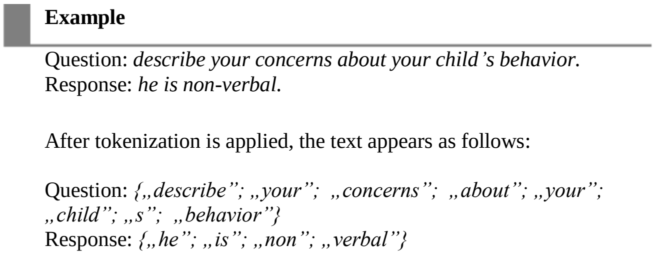
Question: *Describe your concerns about your child's behavior.*
Response: *He does not interact with the other children.*

After capitalization is applied, the text appears as follows:

Question: *describe your concerns about your child's behavior.*
Response: *he does not interact with the other children.*

Fig. 7. Example of applying capitalization to a record from the dataset.

2) Tokenization: Breaking down the text into meaningful element, known as tokens, such as words or phrases, to facilitate manipulation and subsequent analysis [19]. Tokenization is language dependent and involves the removal of punctuation marks from the text. The example in Fig. 8 shows the result of applying tokenization to a record from the dataset. As can be noticed this technique does not take into account words composed by the use of hyphens as "non-verbal". For this reason, engineers must pay attention when using the tokenization technique.



Example

Question: *describe your concerns about your child's behavior.*
Response: *he is non-verbal.*

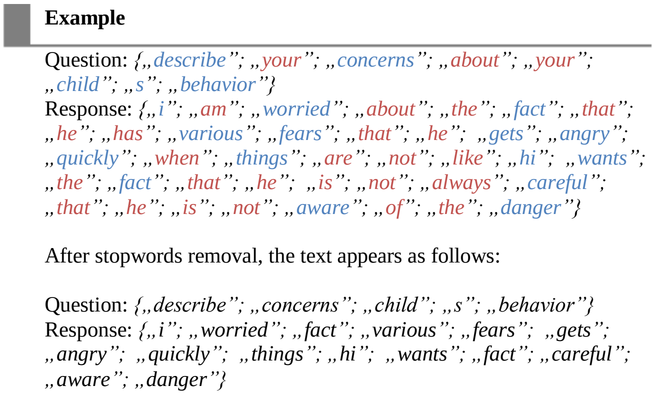
After tokenization is applied, the text appears as follows:

Question: *{„describe"; „your"; „concerns"; „about"; „your"; „child"; „s"; „behavior"}*
Response: *{„he"; „is"; „non"; „verbal"}*

Fig. 8. Example of applying tokenization to a record from the dataset.

3) Filter stopwords: Exclusion of frequently used or rare words called stopwords to reduce the vocabulary size and focus on key words. Stopwords usually are prepositions, conjunctions, auxiliary verbs and pronouns that do not bring significant contribution to the definition of information.

In ADS symptoms detection process was used the Filter Stopwords operator which has a built-in list of stop words for the English language and contains words such as "at", "etc", "if", "or", etc. The Fig. 9 demonstrates the result of filtering stopwords from a parent's response describing concerns about the child's behavior. Words such as "am", "the", "of", "that", "about", "he", "has", "when", "not" and "always" have been removed from the original text, keeping the meaning intact.



Example

Question: *{„describe"; „your"; „concerns"; „about"; „your"; „child"; „s"; „behavior"}*
Response: *{„i"; „am"; „worried"; „about"; „the"; „fact"; „that"; „he"; „has"; „various"; „fears"; „that"; „he"; „gets"; „angry"; „quickly"; „when"; „things"; „are"; „not"; „like"; „hi"; „wants"; „the"; „fact"; „that"; „he"; „is"; „not"; „always"; „careful"; „that"; „he"; „is"; „not"; „aware"; „of"; „the"; „danger"}*

After stopwords removal, the text appears as follows:

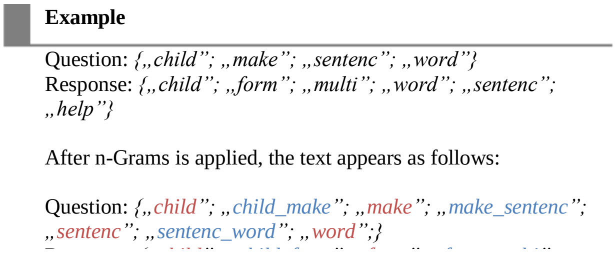
Question: *{„describe"; „concerns"; „child"; „s"; „behavior"}*
Response: *{„i"; „worried"; „fact"; „various"; „fears"; „gets"; „angry"; „quickly"; „things"; „hi"; „wants"; „fact"; „careful"; „aware"; „danger"}*

Fig. 9. Example of applying filter stopwords to a record from the dataset.

4) Stemming: In linguistic morphology stemming is the normalization process of reducing inflected, derived words to their basic form, the root. The root is the part of a word that is common to all its inflected variants. The process of stemming involves removing prefixes or suffixes. To achieve this we used Porter's stemming algorithm. Porter's stemming algorithm removes suffixes from a word, from the English language, to obtain its root [20]. The algorithm consists in marking the consonants in the word with the letter C and the vowels with the letter V. Thus all words can be represented by the Eq. (1).

$$[C]VCVC \ldots [V] \tag{1}$$

5) n-Grams: n-Grams is a text preprocessing method mainly used for feature extraction. An n-Gram is a series of consecutive tokens of length *n* used to capture contextual information and improve the understanding of the text. Fig. 10 shows the result of applying n-Gram to a record from the dataset.



Example

Question: *{„child"; „make"; „sentenc"; „word"}*
Response: *{„child"; „form"; „multi"; „word"; „sentenc"; „help"}*

After n-Grams is applied, the text appears as follows:

Question: *{„child"; „child_make"; „make"; „make_sentenc"; „sentenc"; „sentenc_word"; „word";}*

Fig. 10. Example of applying n-Grams to a record from the dataset.

6) Term weighting: Weighting is the process by which the importance of term in the text dataset is quantified. Each term is associated with a value called a weight, which symbolizes how indispensable it is for the text mining process.

In the automated ADS symptoms detection process, Term Frequency - Inverse Document Frequency (TF-IDF) was used to determine the weights. TF-IDF is a statistical measure intended to quantify the importance of a word in a document or corpus. TF-IDF aims to reduce the influence of common words on the model [21].

F. Machine Learning

ML is a subset of AI that focuses on developing systems capable of learning and making decisions without being explicitly programmed. The automated detection of ASD symptoms in text data involved the exploration of four ML algorithms suitable for training a classification model:

- Naïve Bayes (NB) - The NB classifier is a supervised learning algorithm based on Bayes theorem. The algorithm calculates the probability of each class (labels) and then chooses the class with the most likely probability [22].
- K-Nearest Neighbors (k-NN) - The k-NN is a non-parametric algorithm that operates by finding the K nearest neighbors to a given data point based on a metric such as Euclidean distance. The class or value of the data point is then determined by the average of its K neighbors [23].
- Deep Learning (DL) - The DL algorithm is based on a multi-layer artificial neural network that is trained with stochastic gradient descent using back-propagation. The network can contain a large number of hidden layers consisting of neurons with tanh, rectifier and maxout activation functions [24].
- Radom Forest (RF) - The RF is a ML algorithm that uses an ensemble of decision trees to make predictions. Each decision tree is trained on a different data subset, and the predictions of all trees are averaged to produce the final prediction [25].

In order to identify the algorithm that produces the best performing model for automated detection of ASD symptoms a cross-validation was implemented. Cross-validation is a technique used in ML for assessing and comparing learning algorithms by dividing data into two segments: one used to train a model and the other used to validate the model [26].

The performance evaluation involved calculation of the metrics: accuracy, classification error, Cohen's kappa coefficient, and weighted mean recall. To determine these metrics the confusion matrix was used. Confusion matrix is a performance measurement where the columns represent the predicted values and the rows represent the actual values. According to Kulkarni et al. [27] confusion matrix contains the following elements:

- True Positive (TP): Instances where the model correctly predicted the positive class.
- True Negative (TN): Instances where the model correctly predicted the negative class.
- False positive (FP): Instances where the model incorrectly predicted the positive class.
- False Negative (FN): Instances where the model incorrectly predicted the negative class.

Using TP, TP, FP, FN, and Observed Accuracy (OA) and Expected Accuracy (EA) the follow metrics were determined:

- Accuracy - The accuracy represents the percentage of correct predictions out of the total predictions and is calculated using (2).

$$Accuracy = (TP + TN)/(TP + TN + FP + FN) \quad (2)$$

- Classification error - The classification error represents the percentage of incorrect predictions and is calculated using (3).

$$\text{Classification error} = (FP + FN)/(TP + FP + FN + TN) \quad (3)$$

- Cohen's kappa coefficient – The kappa coefficient is a robust statistical metric that measures the observed versus expected accuracy and is calculated using (4).

$$Cohe's\ kappa\ coefficient = (OA - EA)/(1 - EA) \quad (4)$$

- Weighted mean recall – The weighted mean recall is calculated by taking the weighted mean of negative recall in Eq. (5) and positive recall in Eq. (6).

$$Negative\ recall = TN/(TN + FP) \quad (5)$$

$$Positive\ recall = TP/(TP + FN) \quad (6)$$

III. Results

A. Results for RQ$_1$

Each child with ASD has a unique behavior pattern and level of severity. Some children exhibit signs of autism in early childhood, while others may develop typically in the first few months or years of life, but then suddenly become withdrawn, aggressive, or lose previously acquired linguistic abilities [28]. Fig. 11 presents most common ASD symptoms displayed by children of study participants. The process of automated detection of ASD symptoms in unstructured text data, representing parents' responses to questions about the behavior of their children, was empirical and involved iterative refinement and experimentation with different feature representations and ML algorithms. The results of the performance metrics analysis revealed that the model trained using the k-NN algorithm produces a high accuracy of 78.69% and is feasible for ASD symptoms detection. As we progressed in exploring text mining technology in the ASD field, we identified several important implications for future research:

- The efficacy of the text mining process is contingent upon the size of the data. Identifying ASD symptoms proved to be more challenging in the concise responses provided by parents.
- The text mining technique is negatively influenced by figures of speech such as metaphors, irony, and euphemism and can introduce ambiguity in the interpretation of language. Future research should focus on addressing this limitation by improving algorithms so that they handle figures of speech more effectively.
- The limited diversity of the dataset requires caution in generalizing findings. Future research should include more diverse linguistic expressions and cultural contexts to increase the model's applicability.

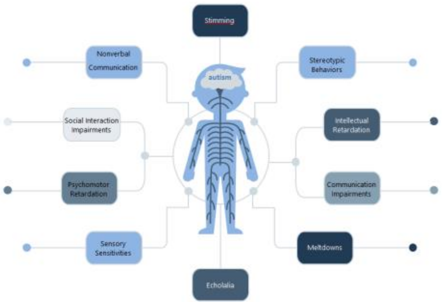


Fig. 11. Most common ASD symptoms exhibited by children of study participants.

The automated detection of ASD symptoms creates opportunities for future research that can further develop healthcare technologies using text mining and ML for autism diagnosis. Automating the symptom identification process provides an efficient alternative to manually reviewing texts written by parents in questionnaires, messages and videos recorded during medical examinations. This efficiency is important for widespread implementation.

B. Results for RQ$_2$

The results obtained from the computation of the accuracy are presented in Fig. 12. The k-NN algorithm outperformed other methods, achieving the highest accuracy of 78.69%. In contrast, the RF algorithm yielded less favorable outcomes, with an accuracy rate of only 54.25%.

The outcomes derived from the calculation of the classification error are depicted in Fig. 13. Analysis of the classification error revealed that k-NN had the lowest error rate at 21.31%, while RF registered the highest classification error of 45.75%.

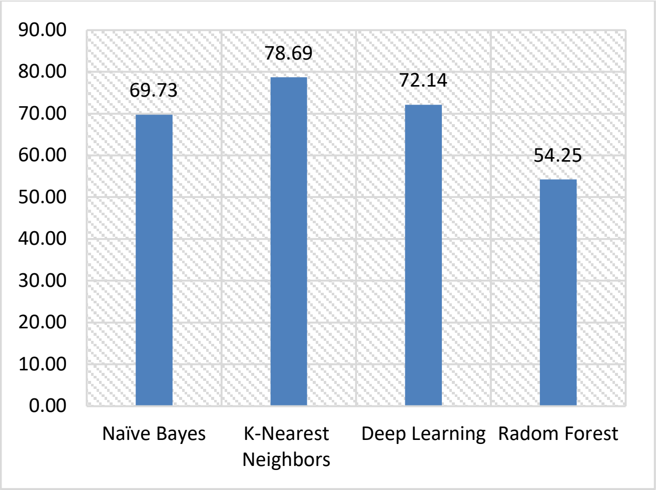

Fig. 12. The accuracy generated by models trained for the automated detection of ASD symptoms.

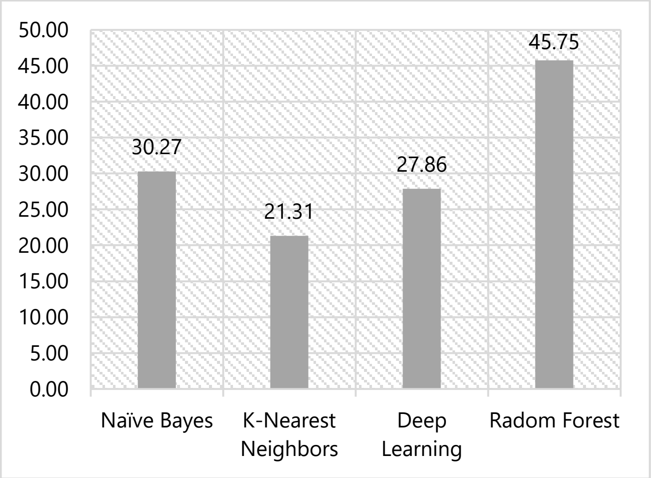

Fig. 13. The classification error generated by models trained for the automated detection of ASD symptoms.

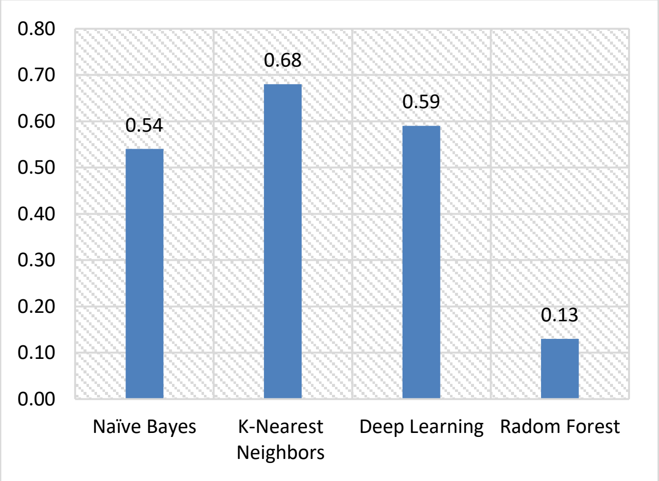

Fig. 14. The Cohen's kappa coefficient generated by models trained for the automated detection of ASD symptoms.

The results obtained after computing Cohen's kappa coefficient are presented in Fig. 14. This coefficient is useful in distinguishing correct predictions that occur by chance and a value below 0.40 is considered unsatisfactory. k-NN demonstrates the stronger association with a kappa coefficient of 0.68.

The results obtained from the computation of the weighted mean recall are presented in Fig. 15 and contribute to the conclusion that k-NN and DL are algorithms that produce more effective models for automated ASD symptoms detection.

Fig. 16 presents the result of testing the model trained using k-NN on a text data that was labeled with the "Communication Impairments" symptom.

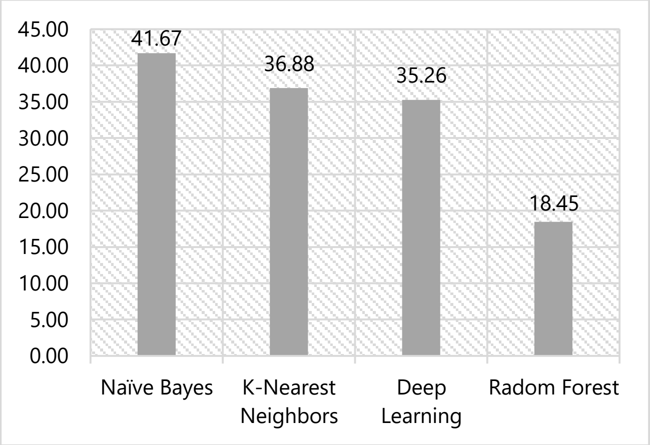

Fig. 15. The weighted mean recall generated by models trained for the automated detection of ASD symptoms.

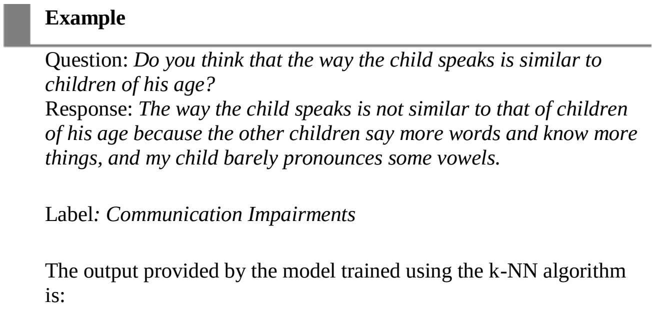

Example

Question: *Do you think that the way the child speaks is similar to children of his age?*
Response: *The way the child speaks is not similar to that of children of his age because the other children say more words and know more things, and my child barely pronounces some vowels.*

Label*: Communication Impairments*

The output provided by the model trained using the k-NN algorithm is:

Fig. 16. Example of testing the model trained with the k-NN algorithm.

It can be observed from the example that through the application of text mining, the ASD symptom "Communication Impairments" was correctly identified. This is impressive, considering that the text included words and expressions that might have posed a challenge for the trained model, such as "know more" or "say more words", which could be associated with positive behavior and the absence of autism markers. This promising result may have significant implications for text mining integration into applications for autism detection.

IV. Conclusions

Text mining is an efficient IT concept for extracting knowledge from text data. The current study explored text mining techniques and methods in a practical way and focused on analyzing text data provided by 44 parents of children diagnosed with ASD, trying to identify linguistic patterns and indicators that may contribute to the detection of ASD symptoms. The data collected from the participants underwent labeling, using a scheme that comprises 19 labels. Of these, 18 correspond to ASD symptoms, while the remaining label is designated as “Asymptomatic”. The dataset was employed to train four predictive models using ML algorithms, including NB, k-NN, DL and RF.

Results obtained through text mining and ML demonstrated the feasibility of using parents’ narratives to develop predictive models for autism symptoms detection. The achieved accuracy of 78,69% highlights the potential of text mining as an autonomous and time- and cost-effective method for the early identification of ASD in children. However, it is important to mention that the ambiguous nature of language can pose challenges in the exploration process and for this reason a representative and diverse training dataset must be employed.

Future research could address the identified limitations and develop healthcare technologies based on the process of detection of ASD symptoms in unstructured text data designed in this study.

ACKNOWLEDGMENT

We would like to express our gratitude to the parents of children with ASD involved in this research for sharing their personal experiences.

***Abstract*—The World Health Organization (WHO) sheds light on the escalating prevalence of heart diseases, foreseeing a substantial rise in the years ahead, impacting a vast global population. Swift and accurate early detection becomes pivotal in managing severe complications, underscoring the urgency of timely identification. While Ventricular Ectopic Beats (V) might initially be considered normal, their frequent occurrence could serve as a potential red flag for progressing to severe conditions like atrial fibrillation, Ventricular Tachycardia, and even cardiac arrest. This accentuates the need for developing an automated approach for early detection of cardiovascular diseases (CVD). This paper presents a novel method to classify arrhythmias. Leveraging the Wavelet Scattering Transform (WST) to extract morphological features from Electrocardiogram heartbeats (ECG), these features seamlessly integrate into a 1D Convolutional Neural Network (CNN). The CNN is finely tuned to distinguish between V, Supraventricular Ectopic Beats (S), and Non-Ectopic Beats (N). Our model's performance surpasses state-of-the-art models, boasting precision, sensitivity, and specificity of 94.56%, 97.26%, and 99.54% for V, and 99.25%, 98.65%, and 93.26% for N. Remarkably, it achieves 68.01% precision, 77.75% sensitivity, and 99.14% specificity for S.**

Keywords*—*Electrocardiogram (ECG); Cardiovascular Diseases (CVD); Wavelet Scattering Transform (WST); Convolutional Neural Network (CNN)

I. Introduction

According to the World Health Organization (WHO), cardiovascular diseases (CVD) stand as the foremost cause of global mortality, contributing to approximately 17.9 million deaths annually. This staggering toll is predominantly attributed to coronary heart disease, encompassing heart attacks, and Cerebrovascular illnesses, including strokes, which collectively account for 80% of these fatalities. The demographic most vulnerable to these health challenges comprises individuals in their middle and elderly years [1]. Clinical research in the preceding century has significantly advanced to facilitate the early detection of CVD. During the historical period when the electrical nature of the heart was widely acknowledged, a notable challenge existed due to the absence of tools for its systematic study. It is noteworthy that the exploration of electricity in the medical domain had commenced nearly two centuries before Einthoven's pivotal contributions. Pioneers such as: Gilbert with his work "De Magnete" in 1600, Bacon through "Novum Organum" in 1620, and Browne who coined the term electricity in the mid-seventeenth century within "Pseudodoxia Epidemica" in 1646, had laid the foundation for understanding electrical phenomena in the context of medicine.

Despite this early groundwork, it was only with Einthoven's groundbreaking efforts that a tangible method, namely the EKG or ECG, was developed to specifically delve into the intricate electrical dynamics of the heart [2]. In the year 1893, Einthoven not only introduced the term "electrocardiogram" but also demonstrated notable advancements by enhancing the electrometer. His significant contributions included the introduction of a correction formula, a pivotal innovation that enabled the differentiation of five distinct deflections [3-4]. These deflections, denoted by the names PQRST, were assigned based on the Cartesian nomenclature.

Comprising P, QRS, and T waves, along with an array of intervals, the electrocardiogram (ECG) serves as a comprehensive diagnostic tool. This intricate waveform not only facilitates the analysis of fundamental parameters such as heart rate but also provides invaluable insights into the intricate conditions and potential risks associated with the heart's functionality [5].

By examining these distinctive components and intervals, clinicians can glean a nuanced understanding of cardiac health, enabling them to address and mitigate potential issues proactively. Determining the signal's classification into the normal range or otherwise relies crucially on assessing the amplitude measured in millivolts and the intervals expressed in milliseconds [6].

Sinus rhythm, denoting the typical heart rhythm, is characterized by the orchestrated propagation of triggering impulses originating from the sinoatrial node. This synchronized transmission extends seamlessly throughout the four chambers of the heart, ensuring a harmonious and coordinated cardiac activity [7]. The underlying cause of Cardiac arrhythmia (ARR) stems from the disruption of proper electrical impulses that orchestrate the coordinated beats of the heart (too slow or too fast) [7]. It is noteworthy that certain ARRs, if left unaddressed, pose a serious threat, potentially leading to sudden cardiac death. Hence, understanding and addressing these dangerous arrhythmic conditions becomes paramount in safeguarding cardiovascular health.

ARRs encompassing four prevalent types: extra beats, supraventricular tachycardia, ventricular ARRs, and brady-arrhythmias [8-9]. Premature (extra) beats include both premature atrial contractions (PAC) and premature ventricular contractions (PVC). Supraventricular ARRs initiate in the atria, characterized by elevated heart rates, they include atrial fibrillation (AF), atrial flutter, paroxysmal supraventricular tachycardia (PSVT), and Wolff-Parkinson-White syndrome. Within the realm of ventricular ARRs lie Ventricular flutter, Ventricular tachycardia (VT), and Ventricular fibrillation (VF).

These potentially life-threatening conditions necessitate immediate intervention, often requiring the prompt administration of a defibrillator shock to safeguard and preserve life. Heart block, a condition that can manifest in the atrioventricular node or the HIS Purkinje system, it leads to an irregular slowed heartbeat, potentially necessitating the use of a pacemaker for treatment. The condition is observed on either the left or right side of the ventricles, identified as right bundle branch block (RBBB) or left bundle branch block (LBBB).

Precise interpretation of ECG signals holds the potential to avert the progression of chronic heart conditions to irreversible stages. However, the manual interpretation and analysis of ECG pose a formidable challenge [10-11]. Moreover, beyond the challenge of manual interpretation, the analysis of long-term ECG signals is a time-intensive endeavor, susceptible to human errors that may compromise the accuracy of assessments [12-13-14, 15].

In recent decades, researchers have responded to the challenges by developing automated models aimed at the detection and in-depth analysis of long-term ECG signals. This innovative approach not only addresses the limitations associated with manual interpretation but also heralds a paradigm shift in enhancing the efficiency and accuracy of cardiac signal assessment over extended periods. These techniques solely rely on advancements in machine learning and deep learning [16-17, 18], which have seen significant progress in recent years, thanks to the continuous development of computer systems and technology.

In the ensuing sections, relevant literature was explored, outlining automated heartbeat classification models. Subsequently, in the methodology, the meticulous preparation and processing of our data were unfolded, the method employed for feature extraction was elucidated, and a comprehensive explanation of the classifier utilized was provided; including its parameters, along with the evaluation metrics employed to assess the efficacy of our proposed model.

Moving forward, the results and discussion section expounded on our findings, drawing comparisons with state-of-the-art systems. Lastly, the conclusion section summarized our results, highlighted the limitations inherent in this study, and proposed avenues for future research to address these constraints.

II. Related Works

A. *Methodology Overview in Previous Studies*

This section introduces state-of-art automated inter-patient ECG heartbeat classification models, adhering to the Association for the Advancement of Medical Instrumentation (AAMI) recommendation [19]. These models categorize ECG heartbeats into five types according to the AAMI standard: Normal (N), Supraventricular ectopic beats (S), Ventricular ectopic beats (V), Fusion beats (F), and Unknown beats (Q), as outlined in Table I.

TABLE I. AAMI Heartbeat Classes

AAMI Classes	**MIT-BIH heartbeats**
N	Normal (N)
	Right bundle branch block beats (RBBB)
	Nodal (junctional) escape beats (j)
	Left bundle branch block beats (LBBB)
	Atrial escape beats (e)
S	Aberrated atrial premature beats (a)
	Atrial premature contraction (A)
	Supraventricular premature beats (S)
	Nodal (junctional) premature beats (J)
V	Premature Ventricular contraction (PVC)
	Ventricular escape beats (E)
	Flutter wave (!)
F	Fusion of ventricular and normal beat (F)
Q	Paced beat (/)
	Fusion of paced and normal beat (f)
	Unclassified beat (Q)

Sellami et al. [20] introduced a deep CNN, leveraging state-of-art deep learning techniques for precise heartbeat classification. They advocated for a batch-weighted loss function to effectively address class imbalances, wherein the loss weights dynamically adjust based on the changing class distribution in each batch. Additionally, they proposed the utilization of multiple heartbeats to enhance the classification of the five heartbeat classes. The evaluation of their proposed approach on inter-patient data from the MIT-BIH arrhythmia database yielded results, their model achieving an accuracy, precision, sensitivity, and specificity of 88.34%, 45.25%, 90.90%, and 88.51%, respectively.

Li et al. [21] employed the overlapping segmentation method to divide ECG signals from the MIT-BIH database into 5-second segments, addressing class imbalances by re-labeling these segments. Subsequently, discrete wavelet transform (DWT) was applied for denoising, and a deep residual CNN was employed for ARR classification. They incorporated the focal loss function. Their proposed method demonstrated a sensitivity, precision, and specificity of 94.54%, 93.33%, and 80.80% for class N. For class S, the model achieved 35.22% sensitivity, 65.88% precision, and 98.83% specificity, while for class V, the method exhibited 88.35% sensitivity, 79.86% precision, and 94.92% specificity.

Garcia et al. [22] presented an innovative approach wherein they proposed an ECG representation based on vectorcardiogram, termed temporal vectorcardiogram. They employed a complex network for feature extraction and fine-tuned an SVM classifier using the particle swarm optimization algorithm. The results of their approach, applied to inter-patient analysis on the MIT-BIH arrhythmia database, demonstrated a precision of 53% for class S and 87.3% for class V.

Wang et al. [23] introduced an automated ECG classification method that relies on Continuous Wavelet Transform (CWT) and CNN. The CWT is employed to decompose ECG signals, yielding distinct time-frequency components. Subsequently, the CNN is utilized to extract features from the 2D-scalogram composed of these time frequency components. 4 RR interval features are extracted and combined with the CNN features and inputted into a fully connected layer. The proposed model demonstrated a sensitivity of 99.04%, precision of 98.04%, and specificity of 87.95% for class N. For class S, the model achieved a sensitivity of 70.75%, precision of 77%, and specificity of 99.51%. Additionally, for class N, the sensitivity, precision, and specificity were 94.35%, 95.32%, 99.45%, respectively.

Takalo et al. [24] introduced a method for inter-patient ECG heartbeat classification, leveraging a deep CNN. Their proposed approach demonstrated commendable performance, achieving a sensitivity of 92% and precision of 97% for class N. Additionally, for class S, the method attained a sensitivity of 62% and precision of 56%. Finally, in the case of class V, their approach yielded a sensitivity of 89% and a precision of 51%.

Junaid et al. [25] proposed a 1D self-organized operational neural network for the inter-patient classification of ECG heartbeats from the MIT-BIH arrhythmia database. Their method exhibited an overall accuracy of 95.99% across: N, S, and V. Specifically, for class N, the proposed method achieved a sensitivity of 98.48%, precision of 97.39%, and specificity of 76.82%. In the case of class S, they attained a sensitivity of 44.01%, precision of 64.50%, and a specificity of 99.01%. Lastly, for class V, the method demonstrated a sensitivity of 92.96%, precision of 89.62%, and a specificity of 99.22%.

He et al. [26] introduced a new method, multi-level unsupervised domain adaptation framework (MLUDAF), for diagnosing ARRs. They used the spatial pyramid pooling residual (ASPP-R) module to extract spatio-temporal features and employed the graph convolutional network (GCN) module for data structure features. In domain adaptation, they aligned domains, semantics, and structures. Testing on MIT-BIH yielded a 96.8% overall accuracy. Notably, the model achieved 97.8% sensitivity and 99.5% precision for N class, 89.2% sensitivity and 90.4% precision for V class, and 90.2% sensitivity and 53.2% precision for S class.

It's crucial to highlight those previous studies have largely overlooked classes F and Q due to their minimal representation (less than 1%) in the MIT-BIH dataset. As these classes make an insignificant contribution to overall performance, they were excluded. Including them in model training would lead to an imbalanced dataset, adversely impacting classification results. Thus, this research focuses exclusively on classes N, S, and V for a more effective analysis.

B. Limitations and Gaps in Previous Studies

It's noteworthy that Wang et al. [23] achieved the best results in distinguishing N, S, and V classes, with an overall accuracy of 97.68%. However, their approach fell short, particularly in classifying S with a sensitivity below 70.75% and limited precision at 77%. Similar limitations were observed in class V, where sensitivity did not exceed 94.35%, and precision reached only 95.32%. This underscores the need for a novel approach to enhance predictions for N, S, and V.

In previous studies, various methods and approaches based on intelligent models have been employed to classify N, S, and V classes, yet the classification results remain inadequate for clinical applications. Therefore, in this research, we aim to investigate the efficacy of a deep feature extraction method using WST, complemented by a second stage feature extraction through 1D CNN. Our objective is to improve prediction and classification results for the three classes.

The rationale for selecting the WST lies in its robust capability to extract both time-domain and frequency-domain features crucial for effectively distinguishing between the three classes. Furthermore, the choice of the 1D CNN in this study is justified by its inherent feature extraction stage, which facilitates the extraction of deeper features. Additionally, the 1D CNN has demonstrated remarkable performance in various classification tasks, underscoring its widespread applicability and effectiveness in classification endeavors.

The combination of these two techniques aims to address the limitations encountered in previous works and improve the prediction accuracy of the 3 ECG classes. This enhancement holds significant promise for advancing the field of automated detection of ARR in ECG. By integrating the WST and 1D CNN, our study seeks to surpass the constraints of prior methodologies and achieve more precise classification results.

III. Materials and Methods

A. Database Description

The research relies on publicly available data from PhysioNet, accessible at the following link: https://www.physionet.org/content/mitdb/1.0.0/. The ECG readings were extracted from the MIT-BIH Arrhythmia database, comprising 48 half-hour excerpts of two channel ambulatory ECG recordings [27].

The recordings were digitized at a rate of 360 samples per second per channel, with an 11-bit resolution over a 10 mV range. The records used in this study are taken from the lead II, because lead II is positioned along the axis of the heart, making it particularly sensitive to changes in heart's rhythm that occur in this plane. So, it’s an important tool for detecting ARRs.

In this study, recordings with paced beats were excluded from the MIT-BIH dataset, specifically four recordings (102, 104, 107, and 217) out of the total 48. The reason for excluding those patients from the analysis was that they had cardiac pacemakers, which had the potential to cause interference.

B. Data Preprocessing

Our study focuses on long-term ECG signals from the MIT-BIH database, aiming to classify heartbeats into three categories: N, S, and V. To achieve this, a QRS detection algorithm is essential for extracting distinct ECG heartbeats from a single recording. Numerous approaches have been explored in the realm of QRS detection, ranging from the foundational Pan-Tompkins algorithm [28] to wavelet-based techniques [29-30], and even machine learning models [31].

In our investigation, the Pan-Tompkins algorithm was opted due to its proven accuracy in QRS detection, achieving an impressive 99.3% accuracy when tested on the MIT-BIH arrhythmia database. Additionally, the algorithm exhibits a lower computational cost compared to alternative QRS detection models. This choice aligns with our goal of efficiently and accurately discerning QRS complexes in ECG signals for subsequent heartbeat classification.

Following the QRS complex detection using the Pan-Tompkins algorithm, 70 samples before and 70 samples after each R peak were extracted, resulting in a total of 141 samples per heartbeat. Fig. 1, Fig. 2, and Fig. 3 depict three distinct types of ECG heartbeats: N, S, and V. To accommodate variations in heart rate, the difference between the post-RR interval and pre-RR interval was incorporated into the samples.

To ensure a fair comparison with previous automated heartbeat classification models, a data split strategy consistent with state-of-the-art approaches was adopted. Similar to these studies, 44 MIT-BIH recordings (excluding four with paced beats) were partitioned into two subsets. Half of the recordings (DS1) were utilized for training, while the remaining constituted the test set (DS2). The distribution of the data used in this paper is outlined in Table II. This inter-patient data split methodology enhances the development of well-generalized model, capable of effectively classifying ECG from new, unseen patients.

In this paper, the DS1 subset was employed for model training and DS2 for testing. A notable observation within DS1 revealed a substantial class imbalance, where the N class boasted 46,596 instances, while the minority classes, S and V, were represented by 1,669 and 3,799 instances, respectively. Recognizing that training on such an imbalanced dataset could skew results towards the majority class and amplify bias, we implemented the Synthetic Minority Over Sampling Technique (SMOTE) [32]. SMOTE proved instrumental in mitigating this imbalance by generating synthetic instances for the minority class. This strategic approach aimed to rectify the skewed class distribution, and foster more equitable representation of each heartbeat type during training. By addressing this imbalance, we sought to enhance the classification performance of our model, ensuring its effectiveness across all classes.

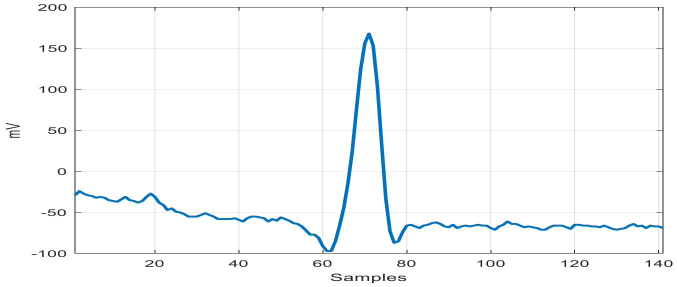

Fig. 1. Non-Ectopic beat.

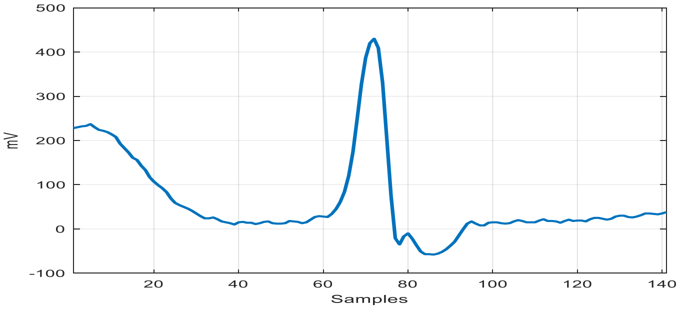

Fig. 2. Supraventricular ectopic beat.

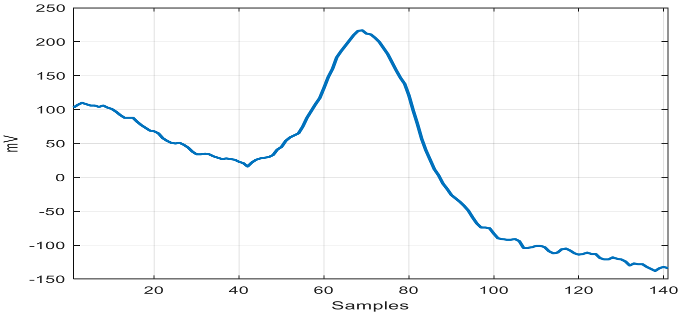

Fig. 3. Ventricular ectopic beat.

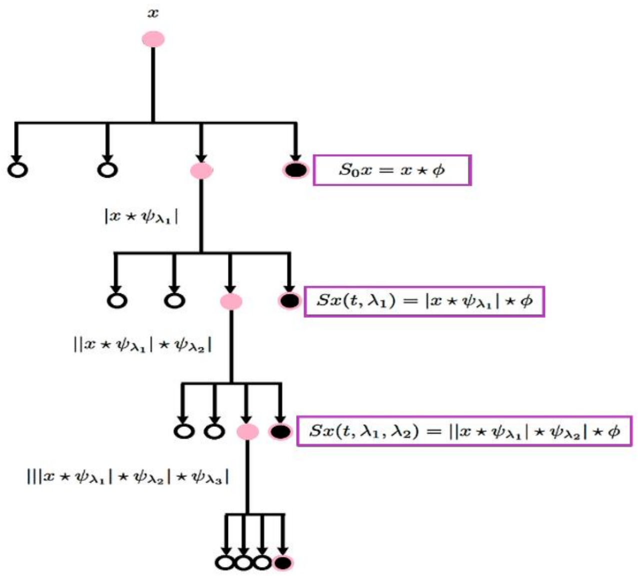
TABLE II. RECORDS AND HEARTBEAT CLASSES PARTITION

Partition	Patients ID	N	S	V
DS1	101, 106, 108, 109, 112, 114, 115, 116, 118, 119,122,124, 201, 203, 205, 207, 208,209, 215,220, 223, 230	46596	1669	3799
DS2	100,103,105, 111, 113,117, 121, 123, 200, 202,210, 212, 213,214, 214,219,221,222,228,231,232, 233,234	43478	1110	3681
Total		90074	2779	7480

C. Deep Features Extraction

To achieve accurate ECG heartbeat classification, it is crucial to employ a feature extraction technique. Two main types of features play a key role in this process: time-domain features, which capture and analyze signal amplitudes over time, and frequency-domain features, providing insights into different signal frequencies. However, traditional approaches like Fourier transform, commonly used for extracting frequency-domain features, lack temporal information, only revealing the frequencies present in the signal. Addressing this limitation, the wavelet scattering transform (WST) emerges as a solution. Fig. 4 illustrates the composition of a wavelet scattering network, featuring multiple layers where WST, akin to a CNN with cascading wavelets, is performed at each layer.

The WST offers features that exhibit stability against deformation, as well as invariance to translation and rotation. Notably, it serves as a potent technique for signal denoising and dimensionality reduction. Applied extensively in audio, image, and 1D signal analysis [33].



x
$S_0x = x \star \phi$
$|x \star \psi_{\lambda_1}|$
$Sx(t, \lambda_1) = |x \star \psi_{\lambda_1}| \star \phi$
$||x \star \psi_{\lambda_1}| \star \psi_{\lambda_2}|$
$Sx(t, \lambda_1, \lambda_2) = ||x \star \psi_{\lambda_1}| \star \psi_{\lambda_2}| \star \phi$
$|||x \star \psi_{\lambda_1}| \star \psi_{\lambda_2}| \star \psi_{\lambda_3}|$

Fig. 4. Scattering network architecture

This paper introduces the Morlet analytic wavelet, offering several advantages. Firstly, being a complex wavelet, it allows the utilization of both its real and imaginary components in convolution processes. Additionally, the wavelet features a low-pass filter represented by the modulus of this wavelet, facilitating down-sampling during the scattering transform.

Moreover, Fig. 5 highlights the remarkable similarity between the shape of this complex wavelet and the QRS complex in ECG heartbeats. This similarity enhances its sensitivity in analyzing and detecting ARR within ECG signals. The expression below represents the mathematical representation of the complex wavelet employed.

$$\psi(t) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{\frac{-t^2}{2\sigma^2}} e^{i\omega t} \tag{1}$$

In the given expression, t corresponds to time, and σ stands for the standard deviation of the Gaussian function. ω is defined as 2πf, where f is the center frequency of ψ, and i is the imaginary unit. The envelope of the complex wavelet is characterized as a low-pass filter denoted as Φ in Eq. (2).

$$\Phi(t) = |\psi(t)| \tag{2}$$

The WST initiates by convolving x(t), which represents the signal being analyzed, with Φ.

$$S_0x(t) = x(t) * \Phi \tag{3}$$

The wavelet function ψ and the low-pass filter Φ are specifically designed to span the entire frequency range of the signal x(t). The low-pass filter introduces a form of averaging, ensuring locally invariant translation features of x. However, the initial order of the Wavelet Scattering Network (WSN) results in the loss of high frequencies, which can be restored by progressing to the subsequent order of the WSN.

In the 1st order of the WSN, an additional convolution was applied using the wavelet ψ_{λ_1} with the scale λ_1. Here, $\psi_{\lambda_1} \in \{\psi_{\lambda k}\}_{\lambda_k \in \Delta_k}$, where, $\psi_{\lambda k}$ represents the multi-scale high-pass filter bank, and Δ_k represents the family of wavelet indices with an octave frequency resolution Q_k.

$$|W_1|x = \{S_0x(t), |x * \psi_{\lambda_1}|\}_{\lambda_1 \in \Delta_1} \tag{4}$$

The 1st order scattering coefficients result from the convolution with the low-pass filter Φ.

$$S_1x(t) = \{|x * \psi_{\lambda_1}| * \Phi\}_{\lambda_1 \in \Delta_1} \tag{5}$$

To retrieve the information (high frequencies) lost during the application of the low-pass filter, the second order of the WSN was proceed.

$$|W_2|x = \{S_1x(t), |x * \psi_{\lambda_1}| * \psi_{\lambda_2}\}_{\lambda_2 \in \Delta_2} \tag{6}$$

Obtaining the 2nd order coefficients of the WSN involves applying convolution with the low-pass filter Φ.

$$S_2x(t) = \{||x * \psi_{\lambda_1}| * \psi_{\lambda_2}| * \Phi\}_{\lambda_2 \in \Delta_2} \tag{7}$$

Similarly, we iterate through this process to determine the coefficients of the nth order in the scattering network.

$$S_nx(t) = \{|..||x * \psi_{\lambda_1}| * \psi_{\lambda_2}| *..\psi_{\lambda_n}| * \Phi\}_{\{\lambda_1..\lambda_n\} \in \{\Delta_1..\Delta_n\}}$$ (8).

The final scattering matrix coefficients represented as:

$$Sx(t) = \{S_0, S_1, \dots, S_n\} \tag{9}$$

In this study, only a 2nd order WSN was used. This is because 99% of the energy of the signal under analysis is preserved in this layer. Furthermore, the addition of more layers to the network would result in a loss of information about the signal and an increase in computational cost.

For the representation of a single ECG heartbeat, applying the WST yields a tensor of size 34x5, which serves as the feature matrix. The scattering coefficients undergo critical down sampling based on the bandwidth of the low-pass filters, generating five-time windows for each of the 34 scattering paths. Each row and column in the tensor correspond to a specific scattering path and time window. Furthermore, the difference between post-RR and pre-RR interval was introduced through feature fusion, oversampling this value by a factor of 34. So, the final representation of the feature matrix is size 34x6. With a total of 48,269 testing instances, this results in a tensor size of 48,269x34x6. Same process is applied to training instances.

Utilizing the WSN with an invariance scale of 0.3 seconds and employing Q_1=8 and Q_2=1 as the quality factors for the 2 filter banks. The frequency bands of the 1st and 2nd filter banks are illustrated in Fig. 6.

Fig. 7 displays the scattering coefficients obtained through the application of WST. These coefficients serve as a visual representation of the hierarchical feature extraction process. The scattering coefficients indicate the presence and distribution of significant features within the signal, offering insights into the signal's composition at various levels.

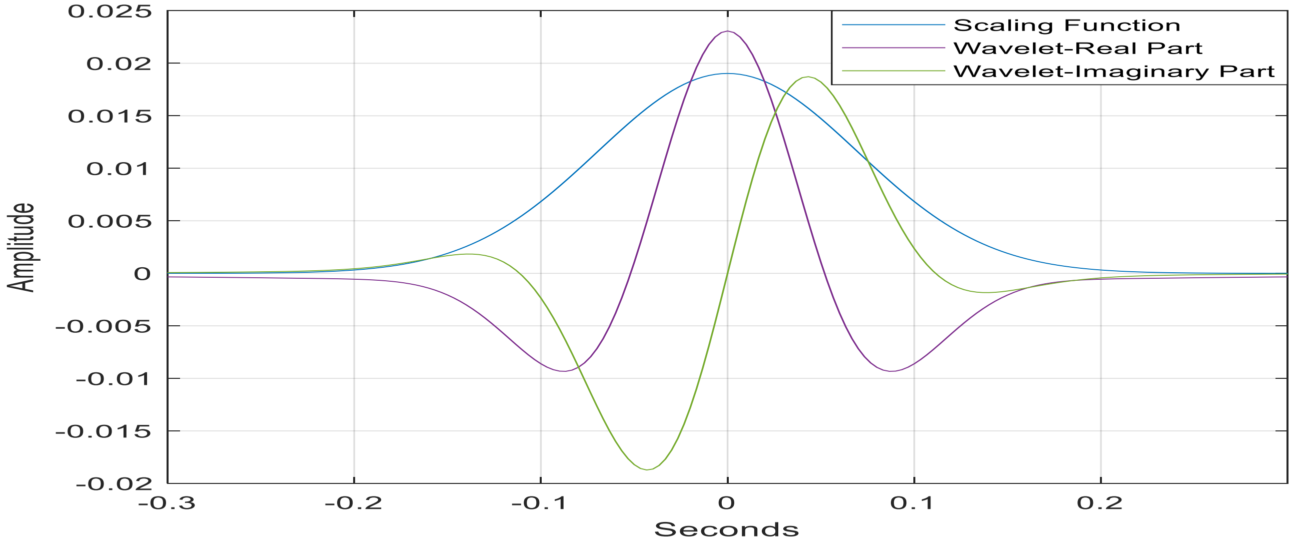


Fig. 5. Morlet Analytics wavelets.

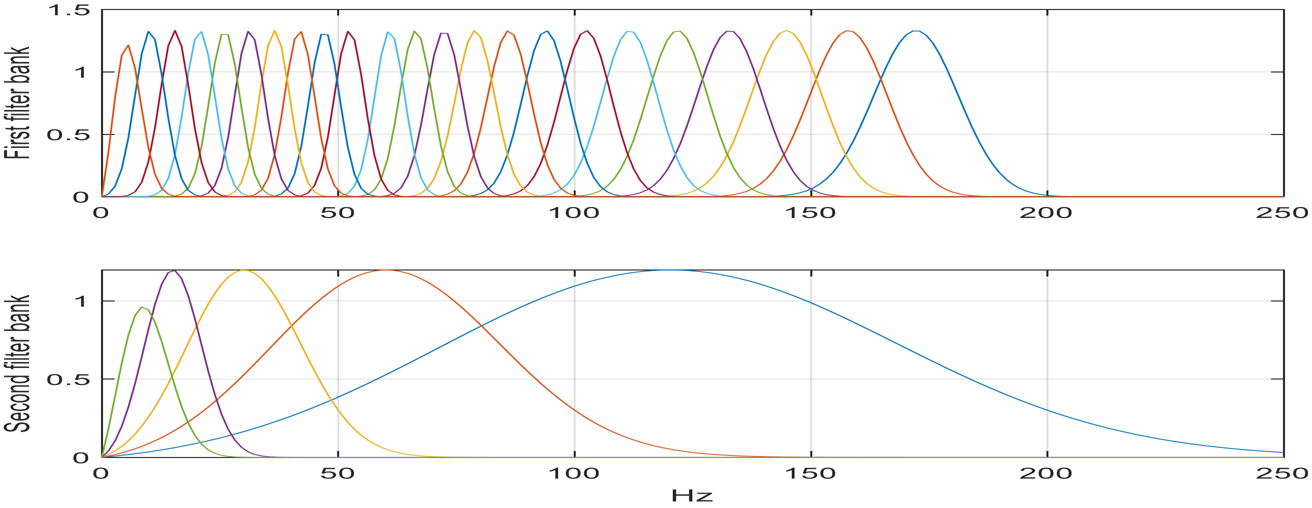

Fig. 6. Frequency bands of first and second filter banks.

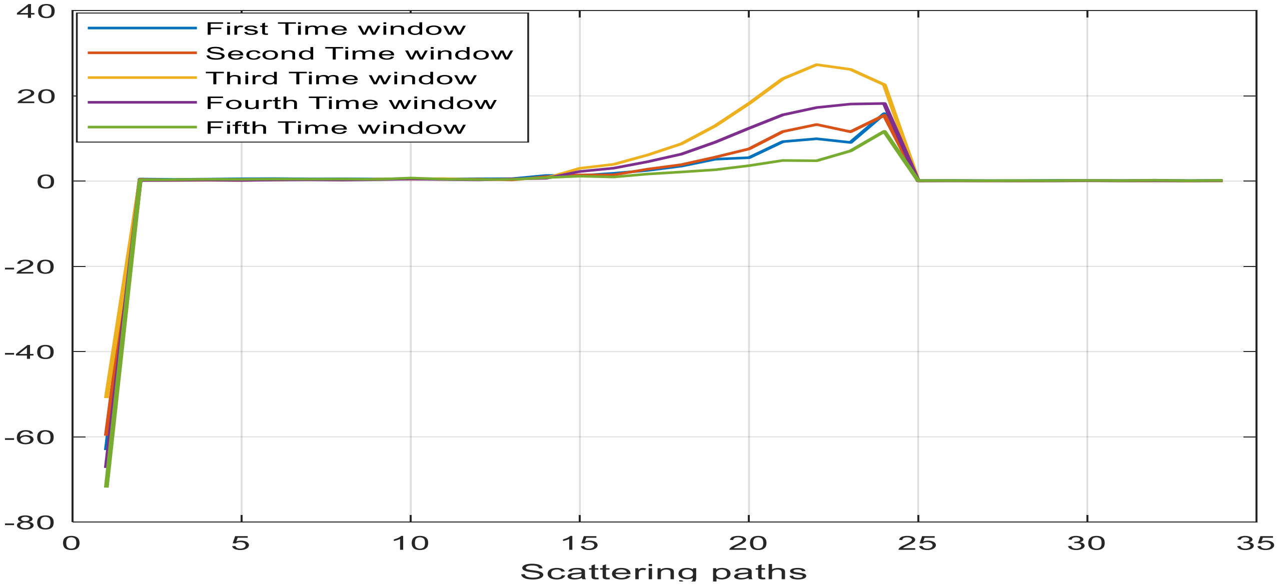

Fig. 7. Scattering coeffecients for one ECG heartbeat.

At a glance, one can observe the dominant patterns and structures captured by the different orders of scattering. Higher order coefficients reveal more intricate details and relationships within the signal, while lower order coefficients highlight foundational features, analyzing the spatial distribution and patterns in these coefficients aids in interpreting the discriminative aspects and inherent characteristics of the signal under consideration. This visual representation enhances the understanding of how the WST effectively captures and organizes relevant information for further analysis.

The WSN was implemented in the MATLAB environment, with the WSN parameters configured for an invariance scale of 0.3 seconds. The sampling frequency was set at 360 Hz.

D. Classification Model

In our research endeavor, a 1D Convolutional Neural Network (1D CNN) was meticulously utilized to address the intricate task of classifying ECG heartbeats into three discernible categories. This deliberate choice of utilizing a 1D CNN stems from its widely acknowledged effectiveness in both the realms of classification and feature extraction, a critical aspect of signal analysis.

The architecture of the 1D CNN unfolds in a systematic manner, featuring two fundamental components. In the initial phase, convolution is employed with fixed-size filters to extract salient features from the signal under scrutiny. This process plays a pivotal role in enhancing the network's ability to discern subtle patterns inherent in ECG data. The subsequent infusion of non-linearity is achieved through the application of the (ReLU) activation function, a prevalent choice in this context due to its efficacy in preventing vanishing gradient.

Moving forward, the convolutional stage is followed by pooling, strategically implemented to reduce the dimensionality of the extracted features. This reduction not only aids in computational efficiency but also enhances the network's ability to focus on the most relevant information for subsequent classification steps.

The final stages of the 1D CNN involve a fully connected layer, which serves as a critical bridge between the extracted features and the subsequent classification process. The output layer, equipped with an activation function tailored for signal classification, culminates in the conclusive step of categorizing ECG signals into their respective classes.

One notable distinction in our approach is the deliberate choice of a 1D CNN over a 2D CNN. This decision is rooted in a keen consideration of computational costs, with the 1D CNN proving to be a more resource-efficient solution. This pragmatic approach underscores our commitment to not only achieving high classification accuracy but also optimizing the computational demands, making our methodology a judicious choice for real-world applications.

Our designed 1D CNN boasts a sophisticated architecture comprising a total of 11 layers. The inaugural layer, known as the sequence input layer, plays a crucial role in organizing input rows as sequences, setting the stage for subsequent treatment. Following this, our 2nd layer takes the form of a convolution layer with a filter size of 3 and 64 filters. Notably, a fixed padding size of [2,0] was employed to enhance the convolutional process. In the 3rd layer, the non-linearity was infused into the model through the ReLU activation function. Finally, the 4th layer introduces a normalization step, a pivotal measure prevented the exploding gradient phenomenon. In the 5th layer, another convolution layer was employed with a filter size of 3 and an increased 128 filters. Accompanied by a padding size of [2,0], this convolutional stage is complemented by ReLU activation and normalization.

The convolution, ReLU, and normalization processes are represented by the following Eq. (10), Eq. (11) and Eq. (12).

$$y_i = b + \sum_{j=0}^{n-1} W_j \, X_{i+j} \tag{10}$$

In the output feature map, y_i represents the output at position i where b is the bias term, w_j is the weight at position j in the filter kernel, x_{i+j} refers to the input at position i+j in the input feature map, and n denotes the width of the filter kernel. The ReLU function sets negatives to zero, leaving positives unaffected.

$$y_i = \max(0, x_i) \tag{11}$$

The normalization process can be modeled as follows.

$$Z = \frac{x - \mu}{\sigma} \tag{12}$$

where, μ designed the mean value and **σ** is the standard deviation.

In the 8th layer, global average 1D pooling is applied to decrease dimensionality. Subsequently, a fully connected layer with an output layer featuring a SoftMax activation function follows. Eq. (13) and Eq. (14) below illustrate the fully connected layer and the SoftMax activation function.

$$Z_j = \sum_{i=1}^{n} W_{ij} \, X_i + \, b_j \tag{13}$$

$$Y_c = \frac{e^{Z_c}}{\sum_{k=1}^{3} e^{Z_K}} \tag{14}$$

where, Y_c is the predicted probability for class c after applying the SoftMax activation function.

Fig. 8 illustrates the architecture of our 1D CNN designed for the classification process, while Table III displays the specific parameters set for training the model.

E. Evaluation Metrics

In assessing the efficacy of our model and conducting a comprehensive comparison with state-of-art models, it becomes imperative to employ a spectrum of performance metrics. Key measures, including accuracy, sensitivity, specificity, precision, and the F1 score, play pivotal roles in providing a nuanced evaluation of the model's capabilities.

$$\text{Accuracy (ACC)} = \frac{\text{TP+TN}}{\text{TP+TN+FP+FN}} \tag{15}$$

$$\text{Precision (PPV)} = \frac{\text{TP}}{\text{TP+FP}} \tag{16}$$

$$\text{Recall or Sensitivity (SEN)} = \frac{\text{TP}}{\text{TP+FN}} \tag{17}$$

$$\text{Specificity (SPE)} = \frac{\text{TN}}{\text{TN+FP}} \tag{18}$$

$$\text{F1 score (F1)} = \frac{2*\text{precision}*\text{sensitivity}}{\text{precision}+\text{sensitivity}} \qquad (19)$$

F. System Description

All algorithms were implemented using MATLAB version R-2021b on a Windows server. The system used for execution had an Intel Core i5 6300U processor running at 2.40 GHz, equipped with 12 GB of RAM, and operated on a 64-bit.

IV. RESULTS AND DISCUSSION

A. Results

This paper introduces an innovative method for classifying ECG heartbeats into three categories (N, S, and V) following the AAMI standard. The primary goal is to improve accuracy, sensitivity, specificity, and F1 score for each class.

To ensure a fair comparison with existing models, the data was divided into two subsets: DS1 for training and DS2 for validation, aligning with the MIT-BIH arrhythmia database.

Our approach begins by employing the Pan-Tompkins algorithm for QRS detection, enabling the calculation of differences between post-RR intervals and pre-RR intervals.

Subsequently, the WST was utilized to extract morphological features from ECG heartbeats. Combining these features with the calculated post-RR and pre-RR results in a 34x6 matrix for each ECG heartbeat. This matrix is then fed into a specially designed 1D CNN for classification, as illustrated in Fig. 9.

By integrating these techniques, the classification performance aimed to be enhanced and contributed to the field of ECG heartbeat analysis.

After training our 1D CNN model with DS1 heartbeats, it was tested on DS2, revealed notable results. Among 43,478 actual N heartbeats, the model correctly identified 42,891, but intriguingly, it misclassified 191 N heartbeats as V and 396 as S. This misclassification stems from the morphological closeness between N and S classes. Similar challenges were observed in the S class, where out of 1,110 actual S heartbeats, 863 were accurately detected, but 232 were misclassified as N and 15 as V.

Conversely, for the V class heartbeats, out of 3,681 actual V heartbeats, the model successfully classified 3,580, with only 91 misclassified as N and 10 as S. This outcome aligns with the distinct morphological differences observed between V and S.

The precision analysis unveils that the model excels in detecting N and V classes but demonstrates lower precision for S heartbeats. This nuanced understanding is crucial, emphasizing the challenges posed by morphological similarities, especially between N and S classes.

The testing data's confusion matrix, depicted in Fig. 10, encapsulates these findings, providing a visual representation of the model's performance across the three heartbeat categories.

Our model's performance was evaluated using various metrics. Based on the confusion matrix in Fig. 10, our model achieved an average accuracy of 98.71% across three classes. The average precision stood at 87.27%, with an average sensitivity of 91.22%. Additionally, an average specificity of 97.31% and an average F1 score of 89.13% was attained.

B. Discussion

In this research, a comparison with state-of-art models was conducted, utilizing the MIT-BIH arrhythmia database and adopting the same inter-patient data partitioning (DS1 for training and DS2 for testing). The results, illustrated in Table IV, underscore the superior performance of our proposed model across various evaluation metrics.

Notably, for the N class, our model demonstrated remarkable precision at 99.25%, coupled with a specificity of 93.26% and F1 score of 98.95%. Furthermore, our model showcased superiority in the S class, achieving a noteworthy sensitivity of 77.75%. This trend persisted in the V class, where our model outperformed the state-of-art models across multiple metrics, attaining a sensitivity of 97.26%, specificity of 99.54%, and an F1 score of 95.89%. These results underscore the efficacy of our model in effectively distinguishing between N, S, and V.

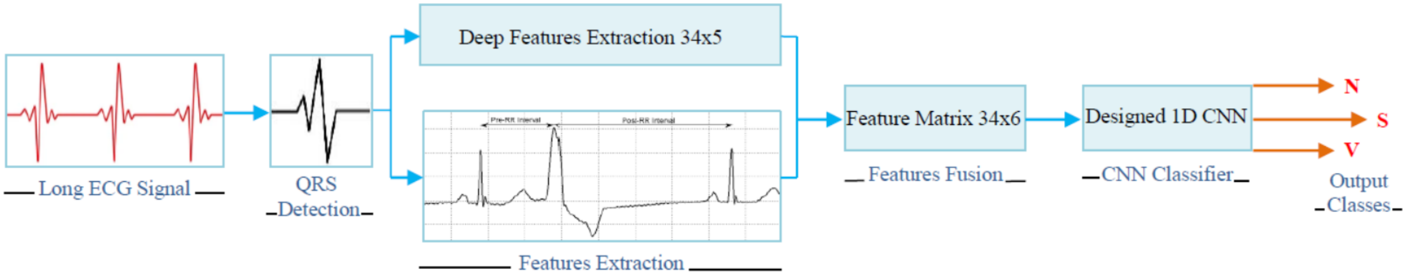

Fig. 9. An overview of the sequential steps for classifying heartbeats

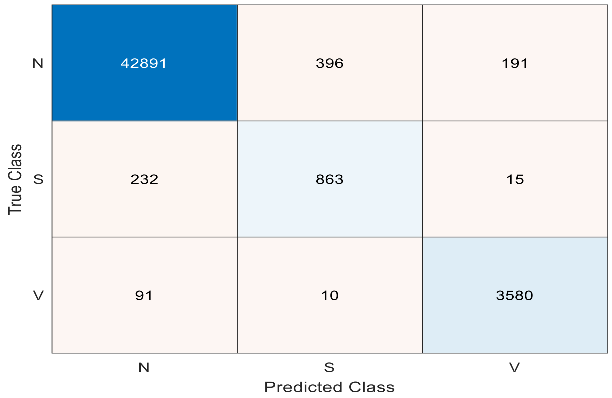

Fig. 10. Testing confusion matrix.

In our investigation, our analysis was extended by comparing the overall accuracy achieved in this study with results from previous works, as detailed in Table V. Sellami et al. [18] achieved an overall accuracy of 92.4% in identifying ECG heartbeats with their proposed approach. In contrast, Li et al. [19] attained an overall accuracy of 88.34% with their method. Among all the other previous works, Wang et al. [21] achieved the highest overall accuracy of 97.68%. The findings reveal that our proposed model successfully detected 47,334 out of 48,269 instances during testing, yielding an impressive overall accuracy of 98.06%. This value signifies that our model accurately classified 98.06% of the tested heartbeats. Importantly, this overall accuracy underlines the superiority of our model over existing automated classification models.

Junaid et al. [23]	95.99
Present Work	**98.06**

V. Conclusion

In this study, an approach was introduced by combining WST for deep feature extraction with 1D CNN classifier. Our model's evaluation, employing inter-patient partitioning, enhances its generalizability for potential clinical applications.

Our results showcase the superiority of our model over state-of-art models. Achieving an overall accuracy of 98.06%, our model excelled in distinguishing between three heartbeat classes. Specifically, it demonstrated a sensitivity of 98.65%, precision of 99.25%, and specificity of 93.26% for the N class. For the S class, our model achieved a sensitivity of 77.75%. Additionally, it outperformed in the V class with a sensitivity of 97.26%, precision of 94.56%, specificity of 99.54%, and an F1 score of 95.89%. These results highlight the significant advancement our model brings to the field.

VI. Limitations and Future work

Despite these successes, our method has limitations. The computational cost of our feature extraction method is notable due to numerous arithmetic operations during convolution. Furthermore, our model shows room for improvement in evaluating the S class, with an F1 score not exceeding 72.55%.

Future work will concentrate on mitigating computational costs by identifying essential wavelets for optimal results. Additionally, we aim to conduct an in-depth analysis of ECG heartbeats to enhance our model's predictive capabilities for the S class. These advancements will further solidify the applicability and efficiency of our proposed method.

Abstract—**The rapidly developing field of "Commercial Operation Divergence Analysis," this research seeks to identify and understand differences in commercial systems that exceed expected results. Approaches in this domain aim to identify the characteristics of process implementations that are associated with changes in process effectiveness. This entails identifying the features of procedural behaviours that result in unpleasant results and figuring out which behaviours have the biggest impact on increased efficiency. As the scale and complexity of big data management and process mining continue to expand, the threat of cyber-attacks poses a critical challenge. This research leverages machine learning techniques for the detection and defence against cyber threats within the realm of big data management and process mining. The study introduces novel metrics such as Skewness, Coefficient of Variation, Standard Deviation, Maximum, Minimum, and Mean for assessing the security state, utilizing variables like SPI, SPEI, and SSI. The research addresses prior issues in cyber-attack detection by integrating machine learning into the specific context of big data and process mining. The novelty lies in the application of Skewness and other statistical metrics to enhance the precision of threat detection. The results demonstrate the effectiveness of the proposed methodology, showcasing promising outcomes in identifying and mitigating cyber threats in the given dataset and which makes use of Support Vector Regression (SVR), has a standard deviation of 0.9, which is consistent with the variability shown in SVM. The results demonstrate a significant achievement, with a Mean Absolute Error (MAE) of 0.98, indicating the efficacy of the proposed approach in providing accurate and timely insights for cyberattack detection and defense, thereby enhancing the overall security posture in data-intensive systems. The results highlight how well the proposed method extracts significant insights from complicated event data, with important ramifications for real-world application and decision-making procedures.**

I. Introduction

Effective extraction operations depend on the deep mine's ability to maintain a healthy and secure air atmosphere [1]. A crucial step in the analysis of data is outlier detection. Hawkins states that atypical is "a thing whether diverges sufficiently form other items as to be assumed that it has been produced by an alternate method" [2]. In 2008, the Global Financial Crisis (GFC) and the demise of the coal mining "super cycle" put a stop to a period of production-focused tactics during which operational costs increased faster than output [3]. Because it presents especially challenging compromises the extractive and material extraction sector is a desirable test case for the study of contamination. Individual plants may provide enormous value, up to millions of dollars annually [4]. Studies had lately claimed that the application of Process Mining (PM) might address these drawbacks through enabling auditors to efficiently and primarily automatically analyse all of the databases employing historic and/or present-day information [5]. Nevertheless, a number of issues brought on by the extraction and use of coal assets, including as sinkholes, erosion of soil, landslides, and the demolition of buildings, have had a significant detrimental impact on the daily lives and assets of local populations [6].

Mining processes is a field of study who tries to enhance process enhancements by offering based on reality observations on previous procedure implementations. The topic sits among system modelling and evaluation and intelligence computing as well as data mine on one's hand. Process variation assessment is described as a collection of methods that allow to contrast more than one event records belonging to various company procedure versions for the purpose to identify the differences between them [7]. A prime instance of contaminated soil includes the soils that make up anthracite mine dumps. The sedimentary layers that cover a coal seam are where the initial soil was formed. The excess soil is typically excavated using various excavators, then delivered into the spoil site via lorries or belt conveyors and deposited form different heights, either with or no choosing the material [8].

Multiple research studies indicate that these last class of computations, machine learning algorithms (MLAs), can be more accurate than statistical methods like discriminant evaluation or logistic regression, particularly if the feature space to be studied is complicated (i.e., once the dimension of the input feature time is believed to be quite large and the connection between the intended contributions along with the feedback transparent include is predicted to be non-linear) and the data sets being used are anticipated to include distinct characteristics [9]. One the contrary, machine learning is a branch of computing which seeks to give machines or different gadgets the capacity to understand sans needing directly controlled. It tries to provide methods and mathematical models for data-driven learning and forecasting. Upon accomplishment, machine learning techniques are used to simulate characteristics of the input in relation to anticipated result, predict production attributes in relation to past information, and characterise the behaviour within the data. A possible approach to predicting wind power using velocity data is machine learning techniques [10]. Machine learning has been immensely successful as information quantities and types have increased because of its ability to examine complex trends in seen information and generate predictive models or choices on fresh data. In the literature, a variety of machine learning methods and algorithms have been published [11].

Predicting how a business operation will behave in the years to come is an essential corporate competence. Procedure prediction, a form of statistical analysis used in management of business processes, uses information from previous process occurrences to forecast future ones [12]. Customer service representatives adjusting to requests about the amount of time left until an issue has been settled are a few examples of use instances. Other use cases include production managers forecasting the length of a manufacturing procedure for improved scheduling and higher utilisation or case supervisors determining probably violations of regulations to reduce business risk [13]. One kind of procedure mining work, called procedure learning, looks for a model that describes the behaviour of an organization's process using information about how it has previously been executed. The log of events is mapped onto a procedure model using a method known as a process identification procedure, which guarantees the model in question is a good representation of the behaviour shown in the event log [14].

Our approach prioritizes adaptability to external influences by employing dynamic updating mechanisms. We continuously monitor cyber security policies, track advancements in attack techniques, and stay abreast of technological shifts. This proactive approach allows us to incorporate new knowledge into our models promptly, ensuring their relevance and effectiveness in evolving cyber security landscapes. Additionally, we leverage techniques such as transfer learning and ensemble methods to enhance model robustness and resilience to changing external factors. The proposed model exhibits robustness to changes in feature selection and extraction methods through rigorous validation and sensitivity analysis, ensuring consistent performance across varying feature sets. Additionally, automating feature engineering enhances efficiency and scalability while reducing the risk of human error, bolstering the reliability and adaptability of our models. Regular audits and oversight mechanisms further reinforce data privacy measures, mitigating potential privacy concerns and promoting responsible data stewardship in cyber security practices. Implementing the methodology may face challenges such as organizational resistance to change, integration with existing infrastructure, and compliance with regulations.

The following are the research Primary Contribution:

- The application of machine learning algorithms allows for improved accuracy and predictive power in identifying the characteristics of process behaviour that contribute to efficiency shifts.
- Machine learning algorithms provide a means to uncover the relevant factors that significantly affect process efficiency. By analysing the event logs and applying the proposed Declare-based coding, the research identifies the most influential aspects of a procedure, allowing organizations to focus on these factors for process optimization.
- The combination of machine learning algorithms and the proposed encoding technique constitutes an effective tool for the analysis of processes.
- The research compares the performance of different machine learning algorithms, such as Standardized Stream flow Index, Gene Expression Programming, Support Vector Regression, and M5 Model Tree. This comparative evaluation helps in understanding the strengths and weaknesses of each algorithm and provides guidance on selecting the most suitable approach for a given context.

Section I, the introduction, provides an overview of the research topic, establishing its relevance and context. Section II, related work, explores existing literature and research in the field to highlight gaps or connections with the current study. Section III, the problem statement, clearly defines the specific issue or gap that the research aims to address. Section IV, methodology, outlines the approach and techniques employed to conduct the study. Section V presents the results and engages in a discussion, while Section VI concludes the research, summarizing key findings and suggesting potential avenues for future exploration.

II. RELATED WORKS

Richetti et al. [15] proposed to determine the aspects of a procedure which most affect its efficiency, they first use Treatment Learning as an original method in the realm of Deviation Mining. This is a novel encoding method enabling vector-based representations of process occurrences. The suggested encoding method may find more expressive solutions since it is built on declaring restriction framework fulfilment. Using publicly accessible logs of events from actual procedures, they do a number of tests that contrast our suggestion to the state-of-the-art activity decoding methods. The findings demonstrated that behavioural learning offered actionable and more descriptive insight from events logs when combined with our suggested Declare-based encoding, making it a useful tool for the analysis of processes.

Al-Shehari et al. [16] proposed the use of feature resizing and quick encoding strategies are used in the framework to alleviate the potential skew of identification outcomes that might emerge from an ineffective decoding procedure. The artificial minority sampling too much method (SMOTE) is additionally employed to alleviate the data set's balance problem. In order to discover a highly precise classification which can identify data leakage events carried out by malevolent outsiders throughout the crucial time when they depart an organisation, renowned machine learning methods are used. By applying our mathematical framework on the CMU-CERT Insider Threat Dataset and contrasting its results with the real world, we demonstrate the notion behind it. The results of the experiment demonstrate that our framework outperforms other methods which have been evaluated on the identical data in terms of detecting internal leakage of information events, with an AUC-ROC value of 0.99. The suggested framework offers practical approaches to deal with potential bias and class imbalance concerns in order to design a system that effectively detects insider data leaking.

Roldán et al. [17] proposed an approach that uses technologies like augmented reality and data mapping to teach workers in assembly operations. Firstly, skilled employees do assembly in accordance with their knowledge using a fully immersive environment. The next step is to use process mining methods to extract assemble model in the logs of events. Lastly, to understand the groups what the expert employees incorporated into the framework, learner employees utilise an improved immersion display with suggestions. Construction block experiments were designed as a toy example, and studies on a group of participants have been conducted. The outcomes demonstrate the suggested education system's competitiveness against more traditional options. It bases itself on procedure mining and mixed reality. In terms of mental effort, vision, learning, outcomes, and how they perform, user ratings are also superior.

Helm et al. [18] proposed 38 procedure mining instances related to health care reported from 2016 to 2018 that discussed the instruments, methods, and methodologies used as well as specifics on how the log data were found to have been medically significant. Utilising the common clinical coding schemes SNOMED CT and ICD-10, researchers then connected the diagnostic characteristics of the patient encounter setting, clinical speciality, and diagnosis of illness. The possible results of utilising a standardised method for categorising medical terms and events log data using common clinical codes are also highlighted.

Weinzierl et al. [19] proposed several prospective business process monitoring (PBPM) strategies that attempt to forecast potential process behaviours while the procedure is being executed. Methods for predicting subsequent event in particular have considerable promise for enhancing practical company processes. Many of these methods use deep neural networks (DNNs) and take into account data pertaining to the environment where the operation is occurring to provide recommendations that tend to be more reliable. Nevertheless, an in-depth analysis of such methods is lacking in the PBPM literature, making it difficult for academics and industry professionals to decide which approach is appropriate for a particular event log. To address this issue, they statistically assess the prediction performance among three potential DNN structures using five tried-and-true encoding methods and five context-rich real-world logs of events. They offer four conclusions that might aid researchers and practitioners in developing fresh PBPM methods for anticipating upcoming actions.

The literature review showcases several developments in machine learning and process mining applications across a range of industries. But there is a clear research vacuum when it comes to combining these technologies to improve cyber security—more especially, when it comes to insider threat defence and detection. Research on process mining, efficiency assessment, healthcare procedures, and prospective business process monitoring has been greatly aided by studies by Richetti et al. [15], Al-Shehari et al. [16], Roldán et al. [17], Helm et al. [18], and Weinzierl et al. [19]. However, none of these studies specifically address the crucial problem of using machine learning for cyber security in the context of Big Data Management and Process Mining. Novel encoding strategies, predictive modelling, or anomaly detection approaches specifically designed for cyber security in massively distributed data settings are not well explored in the literature. This gap in the literature highlights the necessity for a thorough investigation that carefully incorporates machine learning techniques into cyber security frameworks, with an emphasis on the particular difficulties presented by big data and process mining scenarios.

III. Problem Statement

The problem statement of this work is to address the limitations of existing techniques for business process deviance mining. These techniques are based on the extraction of patterns from event logs but have limited expressiveness, particularly in capturing complex relationships in highly flexible processes. The previous research is to apply Treatment Learning, a novel approach in the context of machine learning, to identify the characteristics of a process that have the most significant impact on its performance. The study aims to compare the proposed encoding technique with current process encoding techniques through a series of experiments using publicly available event logs from real-life processes [15]. By incorporating machine learning approaches to strengthen cyber-attack detection and defence mechanisms, particularly within the fields of Big Data Management and Process Mining, the research seeks to expand the breadth of cyber security while boosting the effectiveness and resilience of digital systems.

IV. Regarding Discovery and Declarative Process Modelling

Conventional urgent process diagrams are produced by the majority of mining process methods. These methods work effectively for organised processes since there aren't numerous additional ways an operation may be carried out. Declarative language modelling is suggested as a way to create an improved equilibrium amongst flexibility and guiding support for these types of models, despite the fact that many of these approaches are capable of handling event logs form flexible or unorganised models. Due to expressive modeling's relevance to log files from dynamic or unstructured processes, the potential of mining declarative models has also emerged. Potential bottlenecks may arise in resource-intensive tasks such as model training and feature extraction, requiring adequate computational resources and optimization strategies. To mitigate these challenges, we implement techniques such as data partitioning, caching, and resource allocation optimization to ensure efficient utilization of computational resources and maintain scalability as data volumes increase.

Declaring continues to be the most commonly employed languages for studies regarding declaratory modelling and mineral extraction, although having very little application in business. This is because it's versatile and particularly suited for use in extremely volatile procedures, which are characterised by extreme complexity and variety. The addition enables associations among actions taken upon KiPs to be described using domains limitations as opposed to sequential ordering. Additionally, it enables occurrences in a KiP to signal chronological ties, behavioural consistency restrictions, or choice-of-action relationships in its instances by using these extra notions. Compliance with laws and regulations controlling the application of machine learning for cyber security in various sectors and regions is given top priority in our approach. In addition, we keep clear records of all procedures, guaranteeing responsibility and traceability for our compliance initiatives. On the other hand, difficulties could emerge because regulations are dynamic and have different meanings in different places. The proposed models are designed to complement human-driven cyber security processes by providing automated support in threat detection and response. A collaborative approach where the proposed models serve as decision- support tools, aiding human analysts in identifying and prioritizing threats more efficiently. The models leverage time-series analysis methods to identify and respond to cyclical or recurring patterns in threat behaviour. Through this approach, the models demonstrate the ability to adapt to changes in threat behaviour over different time intervals, ensuring robust and effective threat detection capabilities in dynamic cyber security environments.

Deviance mining with machine learning and declare-based encoding of event logs in rapidly evolving environments like cyber security, where threats change constantly, machine learning models face challenges due to their assumption of stationary data distributions. This means they struggle to adapt to new patterns and trends. To overcome this, techniques like online learning algorithms and anomaly detection are crucial. Online learning allows models to update in real-time, while anomaly detection helps identify unusual behaviour. By employing these adaptive methods, machine learning models can better keep pace with evolving threats and enhance cyber security defenses. Machines are the simplest collection of rules that may be used in machine learning to discriminate between circumstances that include numerous highly weighted classes and scenarios with few strongly weighed categories. Machine learning, within contrast to association-rule mineral extraction, specifies a preferred type worth, that serves as a benchmark for weighing various class values and allows it to highlight machines with strong or poor performance as determined by a particular class characteristic in a dataset. Diverse datasets play a pivotal role in enhancing the generalizability of machine learning models. Models trained on diverse datasets are inherently more adaptable to variations across industries, company sizes, and geographic locations. This adaptability broadens the applicability of the models, ensuring they can effectively perform across a variety of contexts. By exposing the model to a wide range of scenarios and data distributions, diverse datasets enable the model to learn robust representations and patterns that transcend specific instances, thereby enhancing its ability to generalize and make accurate predictions in real-world scenario. Fig. 1 shows the steps to perform dataset encoding and machine learning analysis.

They introduce a unique rules-based technique to analyse company procedure footprints in the next section. By using a machine learner to find those intriguing regulations that have the greatest impact on the results of company procedure cases, our idea builds on previous methodologies centred around rule mining for associations and comparison items sets mine. Usually, indicators of success may be used to track system outputs. As a result, it can be seen trace-level indicators of success as trace-level characteristics that may be utilised as class variables in machine learning applications.

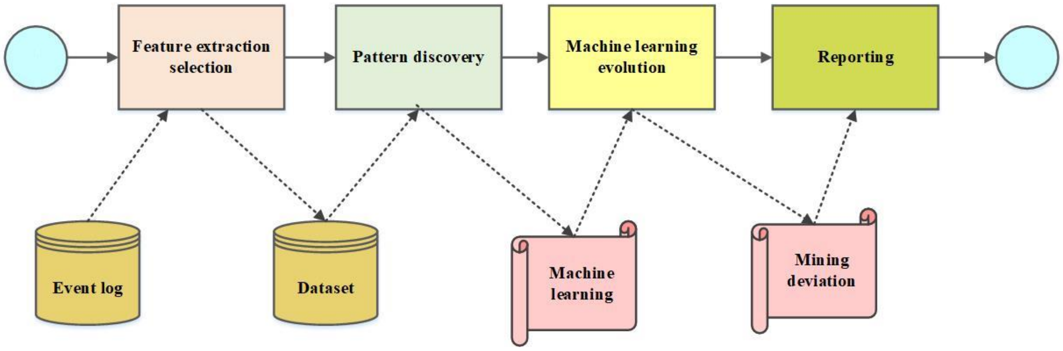

Fig. 1. Steps to perform dataset encoding and machine learning analysis.

It is crucial to bear in mind which (Process Efficiency Indicator) PPIs can be present at additional levels for abstractness in relation to business procedures, such as at the stage of activity, in which a particular task might be tracked from a PPI without consideration of the outcome of every other task carried throughout the same procedure. At the leadership threshold, it can be more important to keep track of a business' overall efficacy, which is often accomplished by combining the findings of a trace-level PPI. For instance, management is interested in monitoring a service level agreement that requires at least 95% of problems to be resolved within 24 hours, thus they would like to measure the amount of incidents resolved in less than 24 hours. This PPI identifies every procedure trail according to its finish time. It is an incorporation of a tracing-level PPI. Trace-level PPIs are of importance for the purposes of this work.

The idea behind machine learning is this, given a realisable choice, demonstrating the disparities among possibilities could prove more obvious than presenting every single event. As opposed to just listing the details of the present-day scenario, a machine learner quickly determines the critical aspects that most affect that circumstance.

A company's record of events might be transformed into a set of data for the purposes of machine learning. Following that, they describe a compression strategy that mines an archive of processes traces for features using declarative mining of processes. Declare's expressiveness is sufficient to record both basic count of each task and complex related to time interactions between pairs of activity. The idea is to use only one, condensed syntax in this manner to record both basic and complicated themes that could be present in an event log. As far that we comprehend, research has not yet investigated a declarative-language oriented encoding strategy to build vector illustrations of process occurrences.

TABLE I. SEQUENCE ENCODING

h_{id}	σ	boa			bigram		mrs		mra	
		x	*y*	*z*	*xy*	*xz*	*xy*	*xyz*	*x,y*	*X,y,z*
h_1	xyzxy	2	1	2	1	1	1	1	1	2
h_2	xyzx	2	1	1	0	1	0	0	1	2
h_3	xyzyzx	3	1	2	1	1	1	1	1	3

Table I is a non-exhaustive illustration of characteristics that may be retrieved given the occurrences of events inside the context of multiple activity traces that together make up a log of events P′. The illustration used known coding methods including bag-of-activities (boa), bigram, maximum repeat sequence (mrs), and maximal repeat alphabet (mra). Such encoding techniques track the frequency with which each encoding pattern is present in the process traces. The choice containing directly extracting tracing-level characteristics off the set h_{attr} of an operation trace and adding those into the collection of instance properties j_{attr} is also taken into account by our methodology. It is feasible to convert the incident log P′ to a datasets after extraction properties from a set of activity traces H ′ by transferring each h to H ′ to a dataset instance q, so that each q = $\left(h_{id}, h_{attr}, c_{name}\right)$, with $q_{1.....n} \in X^{'}$.

TABLE II. EVENT –LOG USING BOA ENCODING

h_{id}	x	y	z	et	Pc (c_{name})
h_1	2	1	2	4.50	false
h_2	2	1	1	3.20	true
h_3	3	1	2	7.30	false

The incident log change example's information is shown in the Table II. Imagine the identical examples traced from before that additionally have additional trace-level characteristics: processing duration (et), in days, as well as effective process conclusion (pc), containing an integer categorization value of "True, False." This provides an illustration of how an event log may be completely transformed into a dataset. A finite a number of occurrences within each trace $h_{1..3}$ may then be encoded using an encoding approach, such as bag-of-activities. Four unique qualities (characteristics) were identified utilising the BOA technique taking into account the peculiarities of the aforementioned activity traces: a, b, and c. It is therefore feasible to create a dataset that includes the gathering of each of the event-driven & trace-level characteristics by taking into account both of the current trace-level characteristics, et and pc. In this manner, the procedure's control-flow and information properties may be examined to one another. In order to connect to the element which serves as the foundation for verifying deviant behaviour, the given name for an attribute of a class (c_{name}) has to be identified in the dataset. The term " c_{name} " must be used to identify a trace-level performance marker that is relevant for examination. False-valued (unsuccessful) footprints are regarded as aberrant instances in our scenario since the effective completion characteristic is specified as a class variable, c_{name} = pc.

A. Mining Declare Constraints as Trace-level Attributes

Compared to the currently used series encoding methods, they also suggest a fresh method employing logical process mining in order for extracting traits from periods of happenings. They took into account the Declaration programming syntax and its restriction examples, which offer the primary relationship and presence restrictions forms. They took into account the meaning of Declare restrictions using standard patterns included in both Unrestricted Miner and MINERFul++ declaratory mining algorithms with the goal to execute the discovery of limitations at the track levels. They must stay away from vacuously fulfilled restrictions since pattern fulfilments are the things that we want to engage in. To eliminate simply met restrictions, a different labelling collection of support automaton for vacuity detecting is suggested. In our search process, the comparable routine expressions used by the vacuity detecting support automata have been taken into account. Declarative syntax mining methods now in use seek to identify a collection of restriction patterns to describe the behaviour of a whole event record as one procedure paradigm. To determine if a restriction template is valid and meaningful, these techniques may take into account several threshold characteristics at the event log level, such as support, confidence, and interest factor. Through examining the achievement of a set Announce specifications for every step in the trace, they hope to employ Declare constraints as features at the trace level in this study. Similar to the previously discussed current encoding methodologies, those Declare-based attributes for each process trace may be used to create a collection of examples.

They use declaratory procedure mined approaches to identify whether Declaration requirements was satisfied in every programme tracing $h \in H$, provided an events log P. A number of Predefined limitations have to be established before mine can be done correctly. A Declaration restriction generators collection may represent all of it or a portion of it in this case. It then needs to be paired to a collection of unique occurrences that are recorded on the occurrence log. This occurrence set includes the parameters that Declaring requirement patterns require in order to function, while this mixture produces the collection of characteristics produced by this encode technique. By creating unique ordinary expressions, the list of default requirement templates may be expanded to include additional restrictions as appropriate. The label of the restriction example, that symbolises an abstraction of a restriction (at first used stated in LTL or via an ordinary expressions), plus a group of parameters are combined to form a Declare restriction d, where d = name ({args}). The total amount of parameters differs based on the pattern; for instance, a init restriction theme only requires a single query since it applies to the occurrence who initiates the trace's execution, but the coexisting restraint pattern requires two inputs because it applies whenever two occurrences occur in the same processes trail.

Considering the occurrence logging instance P ′ from earlier, that includes a collection of three separate occurrences (a, b, and c). Three Declaration requirements init (a), init (b), and init (c) can be produced from a Declaration restriction generator of class init. Every limitations, represented by "1" as a fulfilment or "0" alternatively, makes up as a trace-level attribute-value pairing in the sake of decoding by obtaining an amount matching to the Declaring condition's fulfilment. Common attribute-value pairings associated with the $init$ model, for instance, are as follows: $h'_{attr=((init(a),1),(init(b),0),(init(c),0))}$. The exactly_n model, which counts an exact n of instances of events within the entire track, corresponds to the lone alternative. Activity tracing containing Declare-based attribute-value pairings can then be converted into database objects in a manner similar to that shown in the table for boa coding. A typical dataset is shown in Table III and is made up of objects with characteristics that correspond to an example of Declaration restrictions obtained from the event log P ′. Declare-based characteristics may represent timing connections among actions in a manner that sequence- based set-based encoding methods can't, in contrast with other current encoding methods. For instance, the boa, bigram, mra, and mrs methods do not have an equivalent for the answer (b,c) restriction. Customised constraints for incident sequencing representations of features may nevertheless be defined. Declaring also offers a number of predefined templates that can handle a variety of timing connections between procedure incidents, which is a further advantage. Concerning methodology, each of the four rules may be represented with the current Announce limitation components.

TABLE III. EVENT LOG USING DECLARE ENCODING

h_{id}	Init(x)	Last(x)	Exactly(x)	Response(x,y)	et	pc
h_1	1	0	2	1	4.5	false
h_2	1	1	2	0	3.2	true
h_3	1	1	3	1	7.3	false

B. Machine Learning Evaluation

1) Standardized stream flow index (SSI): Similarly to indicators of severe weather, the majority of investigations used standardised criteria for assessing hydrologic dryness. Two significant standardised indices are flow indices and standardised runoff indices, both which have an analogous theoretical foundation. The sole difference between SSI computations and other computations is that run-off from the surface data are utilised in place of precipitation data. For example, this index displays correct beta dispersion. As a result, for each month, the total flow values are separately estimated before the SSI is computed.

2) Gene Expression Programming (GEP): Genetics can be made using genetic algorithms in the Gene Expression Programming (GEP) algorithm, which uses communities of people and selects these according to fitness. The GEP method's initial step is to create a main collection of answers. This level can be finished by an unintentional procedure or by using some knowledge about the issue. The chromosomal structures were then visualised as a tree expression and evaluated using a fitting method. In general, processing a number of target issues, also known as fitting problems, allows for the evaluation of the appropriate function. The research process ends and the most effective resolution is determined once the answer has an appropriate standard or if a certain number of iterations have passed. The most suitable response form the latest generation is maintained if the most favourable scenario cannot be discovered, and the remaining options are left to be chosen from. The best people are more likely to have children, based on the decision. For many generations to come, every step has been repeated, and it is anticipated the group in question quality will generally increase as new generations are born. GEP chooses the candidates using the renowned roulette wheel approach. In contrast to genetic algorithms and genetic programming, GEP uses a number of genetic operatives to reproduce modified people. Replica is a procedure designed for preserving a few of the most talented members of this era into the following one. A mutation operator's objective is to insert arbitrary changes into an individual chromosome. To avoid producing people deemed rule-deficient, this operator conducts some of the perfect procedures. GEP employs a one-point and two-point combination, similar to a biological algorithm. The genomic equivalent problem (GEP) employs a single-point and two-point combinations. The kind of two-point combo is a little more intriguing because it can largely switch on and off the chromosomal regions that are not encoded. Additionally, the GEP also performs a different kind of combining known as gene combination, in which genes are entirely combined. To create two new children, this operator randomly chooses genes on both-parent chromosomes that are located in the same location.

C. *Support Vector Regression*

Over the following decades, Support Vector Machine (SVM) evolved into a linear classification algorithm using optimum hyper plane concept. Utilising statistical learning theory, this approach is used. Additionally, they utilised kernel algorithms to create nonlinear classifications. SVM's classification algorithm serves to categorise problems associated with data into multiple classes, while its regression technique is applied to solve prediction issues. Regression on fit data produces a hyper plane. A given location's deviation from its hyper plane revealed the inaccuracy of that location. The most effective technique for regression analysis is advised is the least squares approach. But it can happen that using a least-square estimation for analysis issues in the form of outliers may not be entirely rational, which would lead to the analysis performing poorly. In order to avoid bad performance that is not responsive to minute modifications to the model, a robust estimator should be created. As mentioned, the SVM is built upon the principle of minimising risk, a hierarchy generated by the theory associated with statistical training. a distance from real values termed an error function to employ SVM in regression issues that overlook mistakes in a -insensitive manner. This function's definition translates as follows in Eq. (1) and Eq. (2):

$$P(a, f(d,y) = \left|a - f(d,y)\right|_{\varepsilon} \tag{1}$$

$$= \begin{cases} 0 \quad for\ \left|a - f(d,y)\right| \leq \varepsilon \\ \left|a - f(d,y)\right| - \varepsilon\ if\ \left|a - f(d,y)\right| > \varepsilon \end{cases} \tag{2}$$

Below, this mistake function does not take into account errors.

D. *M5 Model Tree*

This technique is an amalgam of machine learning and data mining techniques. Data mining techniques identify several, suitable frameworks before extracting data from a pool of set values. Because data mining techniques differ from statistical approaches because they were established for huge datasets with multiple variables, they were created for smaller datasets with fewer variables. Among the most popular data mining approaches, decision tree-based methods use input data to forecast or categorise target qualities as an output in the shape of an equation having a structure of trees. The M5 modelling trees are a structure of choices that may be utilised for forecasting continuous quantitative qualities. Its branches are representations of regression operate, and it has lately sparked a substantial development in classifications and predictions. When contrasted to other theories, the tree algorithm's data has higher precision and is simpler to replicate and comprehend. A tree of choices is composed of four components: the root, the branch, the nodes, and the leaves. The rectangular shape denoted each node, while the connections between them were shown as branches. The tree of choices usually goes from left to right or from top to bottom, with the base (first node) on the very top to make it easier to create. The leaf denotes the conclusion of a series of events. For the reason of minimising the total of the squared variances from the average information for each node, splitting is carried out by one of the predictive variables. Utilising the splitting criterion is the first step in creating a tree model. The M5 algorithm's dividing criteria relies on the accuracy of the usual variation of the numbers acquired in every node that correspond to every class or subcategory. In a consequence of checking every characteristic at that node, dividing criteria determines the amount of erroneous for that component and determines the smallest predicted error type. In most circumstances, the predictive inaccuracy is determined by assessing how well the desired outcomes for hypothetical cases are predicted. SDR, or standard deviation reduction, is given in Eq. (3).

$$SDR = sd(H) - \sum \frac{\left|H_i\right|}{\left|T\right|} sd(H_i) \tag{3}$$

The total number of specimens approaching all nodes is shown by H, and H_i is the portion of examples which correspond to the nth outcome of a possible test. sd stands for standard deviation. Up till reaching the final cluster (the leaf), the method of division is repeated multiple times at every node. So when it reaches the leaves, the total of the squared differences above the average information is virtually zero. The consequence is going to be the growth of a huge tree. Using numerous limbs and nodes, it is going to difficult to operate using this large tree; as a result, undesirable branches must be removed to create an ideal and effective tree. There are a total of two ways to prune: (1) while the plant forms its full potential, (2) trimming following the peak of shrub development. The second strategy begins by forming the largest possible tree before beginning the trimming manipulate, unlike the initial method, which prevents the tree from growing further branching. Choosing the best branch is dependent on reducing errors in prediction.

E. *Evaluation parameters*

The root mean square error (RMSE) (4), relative absolute error (RAE) (7), mean absolute error (MAE) (5), and correlation coefficient (CC (6)) were used to analyse the error values between the anticipated and observed data.

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(d_i - a_i)^2} \quad (4)$$

$$MAE = \frac{1}{n}\sum_{i=1}^{n}\left|d_i - a_i\right| \quad (5)$$

$$CC = \frac{(\sum_{i=1}^{n} d_i a_i - \frac{1}{n}\sum_{i=1}^{n} d_i \sum_{i=1}^{n} a_i)}{(\sum_{i=1}^{n} d_i^2 - \frac{1}{n}(\sum_{i=1}^{n} d_i)^2)\,(\sum_{i=1}^{n} a_i^2 - \frac{1}{n}(\sum_{i=1}^{n} a_i)^2)} \quad (6)$$

$$RAE = \frac{\sum_{i=1}^{n}\left|a_i - d_i\right|}{\sum_{i=1}^{n}\left|d_i - \bar{d}\right|} \quad (7)$$

When n represents the total amount on assessments, and xi, yi are the anticipated & observed results of the SSI. Complete correlation (CC) among measured and anticipated numbers. Correlation that is direct is shown by values that are positive, and the opposite relationship is indicated by negative values. Additionally, the RMSE and MAE values are errors, therefore smaller values suggest lesser modelling mistakes.

V. Results and Discussion

The effectiveness of the three models—SVM, GEP, and M5—in projecting the Standardised It Index utilising the SPI and SPEI indices at Navrood station throughout six-time delays (a one-month to six-month) is examined in the current work. A 48-month grade was chosen for investigation in this study out of the several scales for predicting SSI since it had a stronger correlation and was predicted by the mathematical models that were provided. The statistical characteristics of the drought indices used in the research region are shown in Table IV.

TABLE IV. Statistical Characteristics of the Utilized Data

SSI	skewness	coefficient of variation	standerd deviation	maximum	minimum	mean	variable
0.69	0.13	958.7	0.98	1.98	-2.09	0.0011	SPI
0.69	-0.69	19.098	0.99	1.45	-2.023	-0.054	SPEI
1	0.08	530	0.99	1.98	-1.67	0.003	SSI

The Fig. 2 shows the Root Mean Square Error (RMSE) values for three machine learning algorithms: GP, M5, and SVR. Each row represents a different evaluation scenario or experiment. The values indicate the accuracy of the algorithms, with lower RMSE values indicating better accuracy. Based on the table, GP consistently has the lowest RMSE values across different scenarios, suggesting it performs better than M5 and SVR in terms of accuracy.

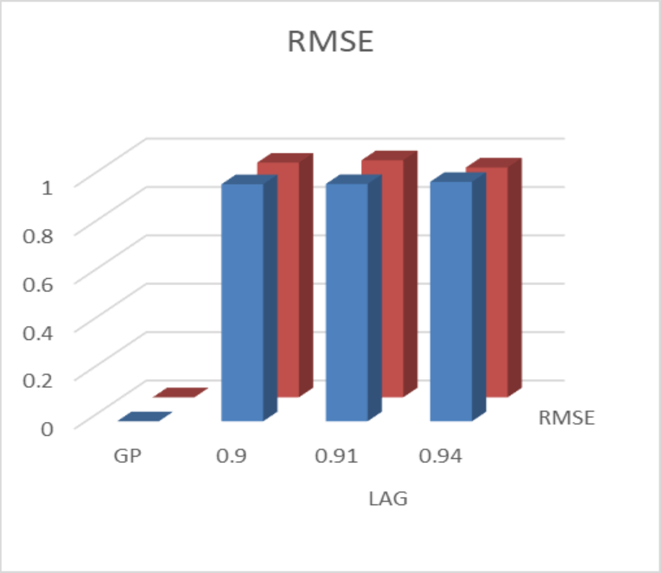

Fig. 2. RMSE model.

The Fig. 3 represents the Mean Absolute Error (MAE) values for three machine learning algorithms: GP, M5, and SVR. Each row corresponds to a different evaluation scenario. MAE is a metric used to measure the average absolute difference between the predicted and actual values, where lower values indicate better accuracy. Based on the table, GP consistently has the lowest MAE values across different scenarios, indicating it performs better in terms of accuracy compared to M5 and SVR.

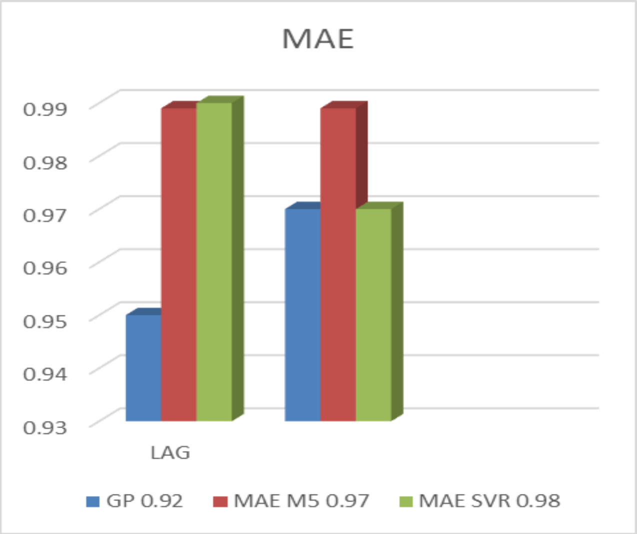

Fig. 3. MAE model.

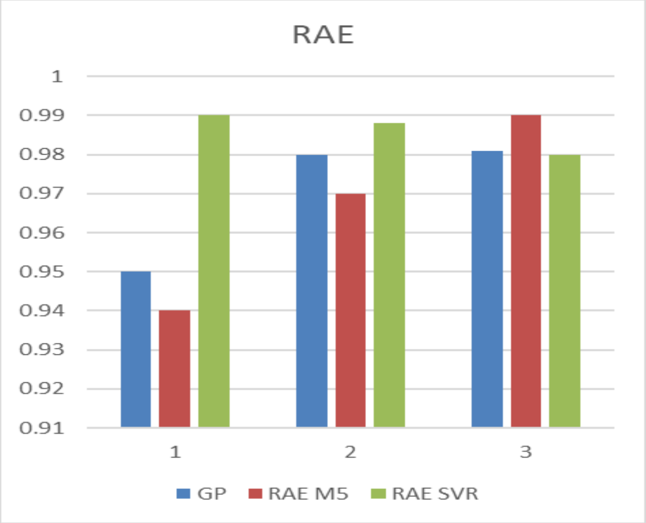

Fig. 4. RAE model.

The Fig. 4 shows the Relative Absolute Error (RAE) values for three machine learning algorithms: GP, M5, and SVR. Each row represents a different evaluation scenario. RAE is a metric used to measure the relative difference between the predicted and actual values, indicating the performance of the algorithms in relation to the magnitude of the target variable. Lower RAE values indicate better accuracy. Based on the table, GP generally has lower RAE values across different scenarios, suggesting it performs better in terms of accuracy compared to M5 and SVR in relation to the magnitude of the target variable.

Additionally, determined by Pearson's correlation but cross-correlation, it was determined that the USDA hydrological dryness index was better and predicted with a smaller error even though the drought index is better and more dependent on climatic circumstances.

TABLE V. PERFORMANCE METRICS COMPARISON

Method	Standard Deviation
SVM [20]	0.9
MLP[21]	0.6
MLP[22]	0.6
Proposed Method	0.9

A comparison of performance measures, namely standard deviations, for various approaches is shown in Table V. The Support Vector Machine (SVM) shows performance variability with a standard deviation of 0.9. Two presentations of the Multilayer Perceptron (MLP) technique are made; in both cases, the standard deviation is 0.6, indicating higher consistency in performance as compared to SVM. Interestingly, the suggested technique, which makes use of Support Vector Regression (SVR), has a standard deviation of 0.9, which is consistent with the variability shown in SVM. These measures provide insights into the stability and reliability of each method, with lower standard deviations often reflecting more consistent performance.

VI. CONCLUSION

The research contributes significantly to the domain of commercial operation divergence analysis, offering valuable insights into the identification of variations in commercial systems beyond anticipated outcomes. By delving into the characteristics of procedure executions, the study illuminates' behaviours impacting process efficiency, encompassing both detrimental and optimal aspects. Success in this context is gauged through domain-specific efficiency metrics, encompassing cost-effectiveness, time optimization, and resource utilization. Users may have concerns regarding the dependability and efficacy of machine learning models in detecting and mitigating threats in applications like cyber security or automated threat detection. It's critical to fully assess the models' performance using real-world data and stringent testing protocols in order to address this. Moreover, adding human supervision to the machine learning procedure might offer still another level of security. Clearly defined procedures for human evaluation and intervention, particularly in crucial decision-making roles can guarantee responsibility and reduce the hazards connected with automated systems. The paper introduces an innovative decoding strategy that utilizes Declare constraint templates, enabling more expressive treatments through vector-based representations of procedure scenarios. Additionally, the research pioneers the application of Machine Learning, incorporating algorithms like Standardized Stream flow Index, Gene Expression Programming, Support Vector Regression, and M5 Model Tree within the realm of Deviance Mining. This approach effectively identifies the aspects of a procedure significantly influencing its efficiency, surpassing traditional trend mining methods to handle intricate linkages within highly variable systems. The experimental outcomes underscore the efficacy of machine learning when integrated with the proposed Declare-based coding. Analysing event logs through this approach yields pertinent and insightful conclusions, offering a comprehensive understanding of process behaviour and performance. While acknowledging these contributions, it is crucial to recognize the limitations of the current study, such as the specific contextual constraints and the need for further validation across diverse industry scenarios. Future work in this field by iteratively validating the model's performance across various data partitions, cross-validation provides a more robust estimate of its generalization ability, helping to identify and address over fitting issues before deployment in real-world scenarios. This research sets the stage for practical and effective tools in process analysis, empowering organizations to make informed, data-driven decisions for optimizing efficiency, reducing costs, and enhancing overall performance.

Abstract—**Federated Learning (FL), a crucial advancement in smart city technology, combines real-time traffic predictions with the potential to enhance urban mobility. This paper suggests a novel approach to real-time traffic prediction in smart cities: a hybrid Convolutional Neural Network-Recurrent Neural Network (CNN-RNN) architecture. The investigation started with the systematic collection and preprocessing of a low-resolution dataset (1.6 GB) derived from real-time Closed Circuit Television (CCTV) traffic camera images at significant intersections in Guntur and Vijayawada. The dataset has been cleaned up utilizing min-max normalization to facilitate use. The primary contribution of this study is the hybrid architecture that it develops by fusing RNN to detect temporal dynamics with CNN for geographic extraction of characteristics. While the RNN's recurrent interactions preserve hidden states for sequential processing, the CNN efficiently retrieves high-level spatial information from static traffic images. Weight adjustments and backpropagation are used in the training of the proposed hybrid model in order to enhance real-time predictions that aid in traffic management. Notably, the implementation is done with Python software. The model reaches a testing accuracy of 99.8% by the 100th epoch, demonstrating excellent performance in the results and discussion section. The Mean Absolute Error (MAE) results, which show a 4.5% improvement over existing methods like Long Short Term Memory (LSTM), Support Vector Machine (SVM), Sparse Auto Encoder (SAE), and Gated Recurrent Unit (GRU), illustrate the efficacy of the model. This demonstrates how well complex patterns may be represented by the model, yielding precise real-time traffic predictions in crowded metropolitan settings. A new era of more precise and effective real-time traffic forecasts is about to begin, thanks to the hybrid CNN-RNN architecture, which is validated by the combined strengths of FL, CNN, and RNN as well as the overall outcomes.**

Keywords—Federated Learning; smart city; convolutional neural network; recurrent neural network; traffic prediction

I. Introduction

Federated Learning which tackles privacy issues and decentralizes model training, is a paradigm shift in machine learning. Due to the transmission and storage of sensitive data, traditional machine learning models are frequently trained on centralized servers using aggregated datasets, which raises privacy concerns [1]. Conversely, Federated Learning enables cooperative model training across decentralized devices, such as servers, edge devices, and smartphones, without requiring raw data exchange [2]. This novel method preserves the privacy of local data while enabling individual devices to make improvements to the model. Federated Learning is a tempting option for applications in healthcare, finance, and, most importantly, the setting of smart cities. It is especially applicable in situations where data privacy is a top priority [3].

The integration of technology to improve urban living is a hallmark of smart cities, and federated learning is essential to this shift. It is clear that efficient and private-preserving machine learning solutions are needed in the context of smart cities, where enormous volumes of data are produced on a regular basis from many sources [4]. Smart city applications that make use of Federated Learning may train models collaboratively with data from disparate sensors, devices, and systems dispersed across the city. This method is especially applicable to situations where precise decision-making requires the aggregation of real-time data, such as energy management, pollution monitoring, and traffic prediction [5].

Because Federated Learning is decentralized and keeps data localized, it naturally addresses privacy issues. To protect contributor privacy, only model changes are shared rather than raw data that is sent to a central server. This is particularly important in smart cities, where there is a need to manage data from several sources carefully, such as public databases, IoT devices, and security cameras [6]. In order to guarantee the safe and private transmission of model changes, Federated Learning also uses cryptographic methods and secures aggregation protocols. Federated Learning is a desirable alternative for implementing machine learning solutions in the delicate and changing contexts of smart cities because of these privacy and security constraints.

Federated Learning presents problems in addition to its many appealing benefits. Non-trivial problems include coordinating model updates from a variety of devices, handling heterogeneous data sources, and controlling communication overhead. Through breakthroughs like federated optimization algorithms, model compression approaches, and effective communication protocols, researchers and practitioners are actively attempting to overcome these difficulties [7]. Federated Learning will be more effective, scalable, and suitable for a larger range of smart city use cases thanks to these developments. Federated Learning is becoming more and more popular in smart cities, as seen by practical uses. Decentralized machine learning is helping smart cities anticipate traffic patterns, optimize waste management, and improve public safety. Success tales emphasize decreased latency, increased prediction accuracy, and above all the protection of citizen privacy. Federated Learning is positioned to be a key player in creating data-driven and privacy-preserving urban ecosystems as smart city programmes continue to grow [8].

Federated Learning has a bright future in smart city applications. Federated Learning is anticipated to become an essential component in the creation and implementation of intelligent systems as technology develops and the need for privacy-preserving solutions increases. The responsible and ethical deployment of Federated Learning in smart city contexts will depend heavily on the cooperation of academics, business, and government in tackling the remaining obstacles. Federated Learning stands out as a critical enabler as cities work to become more interconnected, effective, and sustainable [9]. It provides a means of using the combined intelligence of dispersed data sources while preserving people's security and privacy in urban areas. Smart cities are metropolitan regions that use data and technology to improve the effectiveness and standard of urban living. Cities must manage intricate systems like transit as the globe grows more urbanized in order to provide smooth movement for its citizens. Improving overall urban mobility, streamlining transport networks, and lowering congestion all depend heavily on real-time traffic forecast. The dynamic nature of urban areas presents challenges for traditional approaches of traffic prediction. Using cutting-edge technology like Federated Learning has become a viable strategy to solve these issues.

For efficient urban planning and administration, traffic prediction is essential. It makes it possible for local government officials to improve public transport services, optimize traffic signal timings, and proactively handle traffic congestion. Individual commuters can also benefit from real-time traffic data, which can assist them in making well-informed decisions regarding their travel schedules and routes. Predictive models allow smart cities to be proactive in addressing traffic problems, lessening their negative effects on the environment, and improving the general quality of life for their citizens [10]. By using a decentralized machine learning technique called federated learning, models may be trained on many servers or devices without requiring the exchange of raw data. Federated Learning is an innovative approach for privacy and data security in the context of smart cities. Without jeopardizing personal privacy, traffic data from several sources including sensors, GPS units, and cameras can be used to train models. Through collaboration, heterogeneous statistics from various sections of the city are leveraged to create strong and reliable traffic forecast models.

Federated Learning has many benefits, but there are drawbacks as well. It takes significant planning to coordinate and aggregate models from many places while upholding data security and privacy. Federated Learning implementation in real-time traffic prediction also requires eliminating potential biases and guaranteeing the interoperability of heterogeneous datasets. But there are also a lot of potential since this strategy enables cities to use the combined wisdom of disparate data sources to create traffic forecast models that are more precise and flexible [11]. Several smart cities worldwide have already started exploring the potential of Federated Learning for real-time traffic prediction. Case studies illustrate the successful implementation of this technology, showcasing improvements in traffic flow, reduced congestion, and enhanced transportation services. These examples serve as inspiration for other urban centers seeking innovative solutions to address their unique traffic management challenges. As smart cities continue to evolve, the integration of Federated Learning for real-time traffic prediction holds great promise [12]. The future implications extend beyond traffic management to contribute to a broader vision of sustainable and intelligent urban living. Cities can address existing transportation difficulties and provide the groundwork for a more connected, efficient, and resilient urban future by embracing cutting-edge technology like Federated Learning. The success of smart cities is largely determined by the cooperation of technology, data science, and urban planning; a crucial element of this revolutionary process is real-time traffic forecast.

The research questions for utilizing federated learning for enhanced real-time traffic prediction in smart urban environments may include:

- How can federated learning algorithms be adapted or optimized to effectively leverage distributed data sources for real-time traffic prediction in dynamic urban environments?
- What strategies can be employed to address privacy concerns while aggregating and learning from decentralized traffic data in federated learning settings?
- How can federated learning models be integrated with existing traffic prediction systems to enhance accuracy and reliability in smart urban environments?

The research objectives could be:

- To investigate and analyze existing federated learning algorithms and assess their suitability for real-time traffic prediction tasks.
- To develop novel techniques for privacy-preserving federated learning in the context of traffic prediction, ensuring compliance with regulatory standards and user privacy preferences.
- To design and implement a federated learning framework that integrates seamlessly with urban traffic monitoring systems, enabling real-time data exchange and model training across distributed nodes.

The research significance lies in its potential to revolutionize traffic prediction systems in smart urban environments by leveraging federated learning techniques. By addressing privacy concerns and enabling decentralized model training, this research could pave the way for more accurate, efficient, and scalable traffic prediction systems that can adapt to the dynamic nature of urban environments. Furthermore, the outcomes of this research could have broader implications for the development of federated learning applications in other domains, contributing to advancements in decentralized machine learning and data privacy preservation.

The key contributions of the paper are given as follows:

- The study presents unique hybrid architecture for real-time traffic prediction in smart cities that combines CNN and RNN. This combination of techniques incorporates the best aspects of temporal analysis from RNN, which identifies sequential patterns and relationships in traffic data with spatial evaluation from CNN, which identifies high-level characteristics from static traffic images.
- In contrast to traditional models, the suggested method combines geographical and temporal components for traffic prediction. While the CNN module retrieves static geographical information to provide an extensive understanding of traffic patterns, the RNN component methodically examines sequential data, taking into account unpredictable shifts in traffic circumstances over time.
- The study proposes a paradigm that improves privacy and efficiency by utilizing the concepts of federated learning. The federated learning strategy guarantees decentralized learning, protecting the privacy of individual sources of information while jointly enhancing the global model, by permitting local training on customer devices with locally produced data.
- To maximize the model's performance, the hybrid model uses backpropagation-based training and weight modification techniques. In the end, this increases the accuracy of real-time traffic forecasts by allowing the network to adjust to complicated temporal correlations and geographical patterns in traffic information.
- The suggested architecture is mostly used in the field of smart city traffic management. The model enhances road safety in urban contexts, reduces congestion, and improves traffic flow efficiency by improving real-time traffic forecast skills. The suggested model stands out as a complete response to traffic issues in smart cities due to its holistic approach, which takes into account both static and dynamic elements.

The arrangement of the remaining content is as follows. The traffic prediction literature is illustrated in Section II. The Problem Statement is provided in Section III. The suggested method for predicting traffic in real-time in smart cities is discussed in Section IV. In Section V, the method's performance is compared to earlier approaches, and the performance measurements are illustrated along with a summary of the findings. The conclusion and future works is summarized in Section VI.

II. RELATED WORKS

The widespread use of Internet of Things (IoT) sensors and devices, in conjunction with artificial intelligence, has resulted in the creation of "smart environments [13]." However, these solutions have high latency conditions and more information transmission from a network standpoint. Accordingly, this paper suggests a Federated Learning structure for Real-Time Traffic Calculation, which is supported by Roadside Units for simulation aggregation. The solution envisions learning being done on clients with locally generated information, and fully dispersed on the Edge, with outstanding learning rates, low latency, and less bandwidth consumption. To that end, this paper addresses tools and necessities for FL implementation towards asynchronous traffic estimation, as well as how such an approach could be assessed employing VANET and network simulations. The study first provides a preliminary assessment of a learning model on a group of automobiles that exemplify a distributed learning technique as a practical step. The study intends to employ a distributed technique like to this one in our proposed design. It is necessary to talk about the suggested solution's suitability in situations when vehicular ad hoc networks aren't present. The study should examine the approach's flexibility given that not all places may have a substantial VANET infrastructure.

Since federated learning is decentralized and protects data sources' privacy, it is commonly used in traffic forecasting employment requiring large-scale IoT-enabled sensor data. The current FL frameworks face significant overhead in communication when transmitting changes to parameter values for state-of-the-art deep learning-derived traffic indicators in FL systems, as the models' extensive and deep modelling necessitates the incorporation of a large number of parameters. To address this issue, we provide in this paper a workable FL scheme: Clustering-based modular and Two-step-optimized FL [14]. The suggested plan uses a divide et impera technique to categorize the clients according to how comparable the parameters of their local models are. Researchers include the particle swarm optimization technique and develop a two-phase method for optimizing local models. This technique lowers the communication cost of the model update transmission in FL by allowing just one representative local model upgrade from each cluster to be published to the central server. In order for the gradient compression or sparsification-based techniques to coordinate and minimize communication cost, CTFed is perpendicular to them. Comprehensive case studies utilizing three real-world sets of information and three cutting-edge models show how the suggested approach excels in terms of training effectiveness, precise forecasting performance, and resilience to unstable network settings. The suggested scheme's scalability, however, could have drawbacks. In large-scale IoT-enabled networks of sensors, in particular, the number of clients can lead to computationally demanding clustering and optimization stages that compromise scalability.

Recent developments in cloud computing, which offer near real-time processing along with storage scalability, have accelerated the development of data-intensive smart city applications. Millions of people rely on centralized, effective route planning systems like Google Maps as a result of this. Algorithms for route planning have advanced along with the cloud settings in which they operate [15]. As current state-of-the-art solutions are predicated on a shared memory paradigm, their deployment is constrained to data center multiprocessing scenarios. As a result of centralizing these functions, latency is becoming the limiting factor for emerging technology like driverless vehicles. These services also need connectivity to external networks, which raises questions about availability in the event of a disaster. As a result, this study offers a decentralized method for commercial fog network route planning. The study uses a hypothetical case study from a mid-sized American city to explore our method of cooperatively learning shared prediction models online, using recent breakthroughs in federated learning. However, a number of variables, such as network congestion, device malfunctions, and environmental circumstances, might affect the dependability and accessibility of private fog networks. The article ought to go into how the suggested strategy handles these kinds of obstacles.

Intelligent transportation systems, particularly in urban settings, are undergoing a transformation as a result of the Internet of Things' exponential expansion [16]. Transport network intelligence and efficiency are improved by an Intelligent Transportation System by utilizing data analytics and communication technology innovations. These IoT-enabled ITSs also produce a large amount of complicated data that is categorized as Big Data. Due to the enormous volume, velocity, diversity, and serious data privacy problems associated with Big Data, traditional information analysis frameworks require assistance in order to analyze it effectively. Federated Learning, which is well-known for protecting privacy, is a promising technique that may be used in ITSs to handle Big Data created by IoT devices. However, the variety of data, the varying nature of devices, and the dynamic environment in which ITS functions provide difficulties for the system. The concrete selection of an averaged technique during the server's aggregation phase and the practical training of dynamic clients are the main areas of recent endeavour to address these difficulties. The research that is now available, notwithstanding these efforts, still depends on customized FL with customized averages and customer education. In this study, a tailored architecture utilizing FL for effective and real-time large-scale data analysis in IoT-enabled ITSs is presented, along with an efficient Federated Averaging technique. The conventional averaging process is improved by applying a variety of customizing techniques. Weighted averaging and local fine-tuning adapt the global algorithm to the unique client data. Further performance improvement is achieved by using custom learning rates. To keep the model's efficacy intact, regular assessments are recommended. The suggested architecture provides a complete solution for contemporary urban transportation systems utilizing Big Data, addressing important issues including actual existence federated environment applications integrating information, and substantial data protection. The study implements the suggested methods for vehicle detection on the Udacity Self-Driving Car Database to show our model's effectiveness. The empirical findings confirm the architecture's superiority in terms of data privacy protection, instantaneous decision-making capabilities, and scalability.

Since sharing confidential information puts people's lives in danger, privacy concerns are seen as one of the biggest obstacles in smart cities. Federated learning has shown to be a successful method for both protecting privacy and optimizing data usage [17]. However, the amount of identifiable information acquired in smart cities is limited, while the amount of unlabelled data produced is abundant; this makes the use of semi-supervised learning necessary. We suggest FedSem, a semi-supervised collaborative learning technique that makes use of unlabelled data. The technique is split into two stages, the first of which uses the labelled data to train a global model. To enhance the model in the second stage, the study employs semi-supervised learning depending on the pseudo labelling approach. Utilizing the traffic sign dataset, the study ran a number of tests to demonstrate how FedSem may use unlabelled information to enhance accuracy throughout the procedure of learning by a maximum of eight percent.

Over the next several decades, Artificial Intelligence will revolutionize many aspects of our lives and careers, from face recognition to autonomous driving. Current AI methods for urban computing face several obstacles, such as managing the processing and synchronization of massive amounts of data created by edge devices and protecting user privacy and security, including biometrics, geolocation, and itinerary data [18]. Conventional centralized-based methods need uploading all organizational data to a single database, which may be against the law according to data protection laws like the CCPA and GDPR. Federated Learning, a novel training paradigm, is suggested as a way to separate model training from the requirement to keep the data on the cloud. With FL, the danger of privacy leakage may be greatly reduced as several devices can work together to jointly build a common framework while retaining the training data locally on each device. However, data in urban computing situations are frequently asynchronous, high-frequent, and communication-heavy, which presents additional difficulties for the implementation of FL. The study suggests StarFL, a novel hybrid federated learning architecture, as a solution to these problems. Secure key distribution, encryption, and decryption are made possible by StarFL in conjunction. Additionally, StarFL offers a verification method for every participant to guarantee the confidentiality of the local data. Furthermore, StarFL can offer precise timestamp matching to make it easier for several clients to synchronize. With all of these enhancements, StarFL is now more suitable for use in security-sensitive circumstances in the upcoming urban computing age.

Through decentralized training initiatives, federated learning has already been utilized for a variety of activities in automated transportation systems to preserve data privacy [19]. When it comes to learning spatial information, most of the most sophisticated approaches in automated transportation systems depend on graph neural networks. The present architectures for federated learning in ITS activities utilizing GNN-based models are limited to safeguarding data privacy, and they fail to consider the topological data related to transportation systems. To address this issue, the study presents a unique architecture for federated learning in this study. To safeguard the topological information, the study specifically presents an adjacency matrix preservation method that employs differential privacy. Additionally, the study suggests using an adjacency matrix aggregation technique to provide local GNN-based models access to the global network for improved training outcomes. Additionally, the study suggests the attention-based spatial-temporal graph neural networks model for traffic speed forecasting, which is based on GNNs. For traffic speed forecasting, we combine ASTGNN as FASTGNN with the suggested federated learning system. Numerous case studies using an actual dataset show that FASTGNN is capable of producing precise forecasts while adhering to the privacy preservation requirement.

The fields of real-time traffic estimates and smart city applications have already investigated a number of approaches, such as graph neural networks, semi-supervised learning, and federated learning. Federated learning has proven successful in maintaining privacy, whereas FedSem and other semi-supervised learning techniques have tackled the difficulties associated with using unlabelled data. Transportation systems have used graph neural networks to extract topological information. But these methods frequently run into problems, such scalability problems in large-scale IoT networks, communication overhead, and dependence on specialized federated learning methods. Furthermore, difficulties with data synchronization, privacy issues, and processing needs have been identified. In order to overcome these drawbacks, the research suggests a hybrid CNN-RNN approach to real-time traffic prediction. This model seeks to improve precision as well as effectiveness in smart city traffic management by utilizing the advantages of both spatial as well as temporal analysis.

The proposed utilization of FL for real-time traffic prediction in smart urban environments holds significant promise, addressing issues of privacy preservation and scalability inherent in centralized models. However, several limitations and challenges need to be considered. Firstly, the scalability of FL frameworks, particularly in large-scale IoT-enabled networks, may be compromised due to computational demands during clustering and optimization stages. Additionally, while FL offers privacy protection, the decentralized nature of urban computing environments presents asynchronous, high-frequency, and communication-heavy data, posing challenges for FL implementation. Moreover, existing FL architectures may not adequately address topological data related to transportation systems, necessitating innovative approaches for preserving such information while ensuring privacy. Furthermore, the effectiveness of FL techniques may be impacted by variables such as network congestion, device malfunctions, and environmental circumstances, which could affect the reliability and accessibility of FL-based traffic prediction systems. Thus, future research efforts should focus on addressing these limitations to realize the full potential of FL in enhancing real-time traffic prediction in smart urban environments. Table I shows the advantages and disadvantages of existing methods.

TABLE I. ADVANTAGES AND LIMITATIONS OF EXISTING APPROACHES

Authors	Methods	Advantages	Limitations
M. V. S. da Silva, L. F. Bittencourt, and A. R. Rivera,	Utilizes FL for real-time traffic prediction, supported by Roadside Units for simulation aggregation. Learning done on clients with locally generated data, dispersed on the Edge, with low latency and less bandwidth consumption.	Decentralized model training enhances privacy protection. Scalability due to distributed nodes.	Computational demands in large-scale networks may compromise scalability. Challenges with data synchronization and communication overhead.
C. Zhang, L. Cui, S. Yu, and J. J. Q. Yu,	Uses divide et impera technique to categorize clients based on local model parameters. Incorporates particle swarm optimization and two-phase optimization for local models, reducing communication costs.	Reduction in communication overhead. Effective training and precise forecasting performance. Resilience to unstable network settings.	Computational demands during clustering and optimization may affect scalability.
M. Wilbur, C. Samal, J. P. Talusan, K. Yasumoto, and A. Dubey	Hybrid federated learning architecture with secure key distribution, encryption, and decryption. Offers verification method for data confidentiality and precise timestamp matching for synchronization.	Enhanced security and privacy protection. Precise timestamp matching improves data synchronization.	Complexity in implementation and management. Potential performance overhead due to encryption and decryption processes.
S. Kaleem, A. Sohail, M. U. Tariq, and M. Asim,	Tailored architecture for real-time data analysis in IoT-enabled ITSs. Improves conventional averaging process with customizing techniques like weighted averaging, local fine-tuning, and custom learning rates.	Improved data privacy protection and model effectiveness. Scalability with efficient customization techniques.	Complexity in customization and management. Potential performance overhead due to customization processes.
A. Albaseer, B. S. Ciftler, M. Abdallah, and A. Al-Fuqaha,	Utilizes both spatial and temporal analysis for real-time traffic prediction. Combines advantages of CNNs and RNNs.	Improved precision and effectiveness in traffic management. Enhanced capability for spatial and temporal analysis.	Potential complexity in model architecture and training process. Dependency on accurate data synchronization and integration of spatial-temporal features.

III. Problem Statement

Prior research in the field of smart city applications has examined a number of strategies, including semi-supervised learning, and graph neural networks, with a focus on real-time traffic estimates. Although federated learning has shown promise in protecting privacy and maximizing data use, large-scale IoT-enabled networks may provide difficulties for current models due to high communication cost and scalability constraints. Furthermore, other research has addressed data security, synchronization, and topological data preservation difficulties. These initiatives, however, frequently have their own set of drawbacks, including high processing requirements, dependence on tailored federated learning strategies, and challenges managing asynchronous and highly communicative urban computing settings [20]. This paper suggests unique hybrid CNN-RNN architecture for real-time traffic forecasting in smart cities in light of these factors. By combining the advantages of recurrent neural networks for temporal evaluation and convolutional neural networks for spatial extraction of characteristics, the suggested model seeks to address the noted limitations and offer an efficient method for traffic prediction that takes into account both the static and dynamic aspects of the data.

IV. Federated Learning for Real-Time Smart City Traffic Forecasting

In order to develop hybrid CNN-RNN architecture for real-time traffic prediction, two steps are involved in the proposed approach: first, data collecting and pre-processing. A systematically low-resolution dataset of 1.6 GB was created by methodically gathering real-time CCTV traffic camera images from important crossroads in the cities of Guntur and Vijayawada under a variety of situations. The dataset was pre-processed, using min-max normalization to normalize pixel values, to improve usability. Next, the suggested hybrid model combines RNN to capture temporal elements of traffic data with CNN for extracting geographical features. The RNN uses recurrent interactions to preserve hidden states for sequential information processing. The CNN uses static traffic images to extract high-level spatial information. By utilizing weight adjustment and backpropagation-based training, this hybrid CNN-RNN architecture intends to enhance traffic management in smart cities by improving real-time traffic prediction while taking into account both static and dynamic features. Fig. 1 shows the overall architecture of the proposed approach.

A. Data Collection

In order to create the dataset for our study, "Leveraging Federated Learning for Real-Time Traffic Prediction in Smart Cities," real-time CCTV traffic camera images were systematically gathered. Our study was aimed at capturing the dynamics of traffic flow in the well-known towns of Guntur and Vijayawada. Particularly, information was gathered at important crossroads in Guntur City, such as Brundhavan Gardens and Guntur Market, as well as in Vijayawada at Benz Circle, Seetharamapuram, Guru Nanak Colony, and Ramavarappadu Junction. The study measured the time it took for a vehicle to travel from one intersection to the other endpoint for each junction, taking into account four different signal points. The network of eighty-three cameras that have been strategically positioned around the cities to provide an accurate representation of various traffic situations is included in the dataset. The study collected 1.6 GB of information in total for our trials. The images in the collection are intentionally low-resolution, having been taken in a variety of lighting situations, perspectives, and locations. Every image has a fixed dimension of 800 pixels for width and 600 pixels for height. The goal of this dataset is to improve the effectiveness of traffic management in smart cities by facilitating the study of real-time traffic forecasting algorithms within the context of federated learning [21].

Prediction of Real Time Traffic in Smart Cities Utilizing Hybrid CNN-RNN
Performance Evaluation

Fig. 1. Overall architecture of the proposed approach.

B. Pre-processing Employing Min-Max Normalization

In advance of employing the CCTV image collection for any analytic or deep learning tasks, pre-processing is required to make it more usable. The collection, which was gathered by traffic cameras, consists of 1.6 GB of indistinct images that have been taken under different lighting conditions. The width and height of every image are 800 and 600 pixels, respectively. Given the heterogeneity of the images in terms of angles, light levels, and climatic conditions, pre-processing is necessary to preserve consistency and compatibility for the operations that follow. The pixel values must be scaled, normalized, and min-maxed in order to bring them into a common range for effective assessment.

Feature scaling, also known as the min-max normalization process, is a crucial step in the pre-processing of images. This technique involves rescaling the image's pixel values such that they fall into a certain range, usually [0, 1]. This uniformness the intensity levels across all images, lessening the effect of variations in illumination and pixel dispersion of values. The two main steps in the min-max normalization procedure are determining the maximum and lowest values for each pixel in the dataset and then using a linear transformation to change each pixel's original value to one that matches inside the specified range. This process helps to produce more accurate and consistent results in machine learning and subsequent assessments. It also improves image consistency. Before the dataset is subjected to min-max normalization, the minimum and highest pixel values for each picture in the dataset are first established. The least significance in the dataset denotes the lowest pixel, while the highest value indicates the most lighted pixel. After these values have been determined, each pixel's initial intensity value is linearly altered to a different value that falls inside the [0, 1] range. Eq. (1) gives the formula that was applied to this conversion.

$$P_{out} = (P_{in} - Min)\frac{newMax - newMin}{Max - Min} + newMin \qquad (1)$$

Following min-max normalization, the resulting image is calledP_{out}, and the new minimum and maximal intensities are called $NewMin$ and $newMax$. P_{in} represents the initial real-time traffic image; Min and Max, respectively, represent the lowest and highest intensity standards, which extend from 0 to 255. This alteration was applied to every image in the dataset, ensuring that the pixel values were consistent and suitable for additional processing. By eliminating biases resulting from variances in pixel values and illumination, this normalization approach helps to improve the dataset's suitability for accurate and consistent evaluation.

C. Prediction of Real Time Traffic in Smart Cities Utilizing Hybrid CNN-RNN

Feature extraction, a crucial stage in computer vision applications, uses convolutional neural networks to capitalize on the unique qualities of the network, such as weight sharing and local connection. CNNs comprise of layers of convolution that adjust to express unique qualities within input images and pooling layers that integrate shift consistency. When interpreting an input image's characteristic, the CNN demonstrates exceptional characteristics including weight sharing and local connectivity to the neurons. The layers of CNN are the pooling layer, which ensures shift invariance, and the convolutional layer, which grows to reflect the unique qualities of the input image.

The nearest group of neurons in the layer before the resultant layer will supply input to the convolutional layer's neurons. The different unique representations were produced by combining many kernels from the preceding layer. Eq. (2) is used to build the convolution layer.

$$v_d^j = \sigma\left(\sum_{i=1}^{d_{j-1}} v_l^{j-1}, M1_{ld}^j + b1_d^j\right), d\,\epsilon[1, d_1] \qquad (2)$$

The $(j-1)^{th}$ layer's l^{th} activation map is denoted byv_l^{j-1}, the j^{th} convolution layer'sd^{th} activation mapping is suggested byv_d^j, and the weight connecting the d^{th} layer's lth activation map at position can be determined by $M1_{ld}^j$ and $b1_d^j$. The different filters in the d^{th}layer may be described by both l_1 and the elementwise exponential activation function.

Although the pooling procedures possess the required information, they might reduce the activation map's spatial dimension. Eq. (3) yields $v_f^j(x, y)$ when the output of the previous layer is handled bitwise nonlinear activation and curled with the dimensions (p, q) in the convolution filter. The positions of the kernel are a1 and b1.

$$v_d^j(x, y) = \sigma\left(\sum_{l=1}^{d_{j=1}} \sum_{a1=0}^{q=1} \sum_{b1=0}^{q=1}\left(M1_{ld}^j(a1, b1) \otimes v_l^{j-1}(x + a1, k + b1) + b1_d^j\right)\right), d\,\epsilon[1, d_1] \qquad (3)$$

The convolution layer was supervened by the location of the d^{th}activation map of the $j+1^{th}$ pooling layer by obtaining the results of the previous layer with a filter of size (2, 2). This resulted in the production of$v_l^{j+1}(x, y)$, which was then used to perform bitwise nonlinear activation using Eq. (4).

$$v_d^{j+1}(x, y) = \sigma\left(\sum_{l=1}^{d_{j=1}} \sum_{a1=0}^{q=1} \sum_{b1=0}^{q=1}\left(M1_{ld}^{j+1}(a1, b1) \otimes v_l^j(2x + a1, k + b1) + b1_d^{j+1}\right)\right), d\,\epsilon\left[1, d_{j+1}\right] \qquad (4)$$

Enhancing efficacy and safety in real-time traffic estimation has been demonstrated through the application of federated learning approaches. Following the crucial step of using convolutional neural networks to extract characteristics, RNNs are utilized to assess the temporal aspects of traffic data. RNNs are an effective solution since they perform well in tasks involving sequential data when prediction and modelling traffic patterns over time. The CNN's output, which typically consists of high-level features and spatial representations taken from static traffic images, serves as the RNN's input. This input includes crucial information about the current traffic flow, including vehicle locations, concentrations, and movement patterns. But traffic conditions are dynamic and ever-changing by nature. To effectively manage traffic and make choices, it is important to consider the temporal linkages and sequential nature of traffic information.

RNNs are efficient at processing the sequential data because of their recurrent interactions, which allow them to maintain a hidden state that accumulates data from earlier time phases. Because of this hidden state, which acts as a memory, the network may retain and utilize data from earlier traffic measurements. The RNN systematically analyses the incoming input at each time step, updating its hidden state and producing output predictions in the process. This method enables RNNs to identify complex temporal correlations and patterns in the traffic information, such as variations in traffic flow and congestion and recurring patterns at specific times of the day. The hidden state at time step t, denoted asrr_t, is found by applying Eq. (5) to the previously calculated hidden state, r_{t-1} and the current input,y_t.

$$r_t = d(M_{ir}y_t + M_{rr}r_{t-1} + b_r) \quad (5)$$

The weight matrices in this instance are M_{rr}andM_{ir}, the bias terma_r, and the activation function d, which is usually a reconditioning linear unit (ReLU) function or a hyperbolic tangential (tanh) function. The output at time step t, or asy_t, is given by Eq. (6) and is generated based on the hidden state that is in effect at that moment.

$$x_t = h(M_{r0}r_t + b_0) \quad (6)$$

where, M_{r0} is the weight matrix and b_0 is the bias factors for the resulting layer. RNNs employ recurrent links to store information from previous stages of time. The hidden state r_t is found using the current input y_t and the hidden states r_{t-1} which appeared before it. The network may be trained and its weights and biases adjusted by using backpropagation across time. This enables the network to identify and respond to temporal trends in the traffic data. In smart cities, traffic management solutions may leverage RNNs' capacity to anticipate traffic in real time, improving flow, reducing congestion, and enhancing road safety. In the context of smart city applications, effective traffic management is essential to maintaining vehicular flow and improving urban mobility as a whole. This research suggests a hybrid strategy integrating CNN and RNN for addressing the problems related to real-time traffic estimation. First, from static traffic images, features are extracted using CNNs, which are particularly good at extracting high-level characteristics and spatial representations. Convolutional and pooling layers make up the CNN layers, which use weight sharing and local connection to identify distinctive features in input pictures. The usage of RNNs is then extended to evaluate the temporal dimensions of traffic data, taking into consideration the dynamic and ever-changing characteristics of traffic situations. RNNs are efficient at processing sequential data, which enables them to model and forecast traffic patterns in the long run. The hybrid model can identify both temporal and geographic correlations in the traffic information because the CNN's output, which represents high-level spatial information, is introduced into the RNN. This combined CNN-RNN architecture shows how to estimate traffic in real time while taking into account both the static and dynamic aspects of the data. Recurrent interactions are used by the hybrid model's RNN component to preserve a hidden state that gathers data from previous time periods. Fig. 2 shows the architecture of the hybrid CNN-RNN.

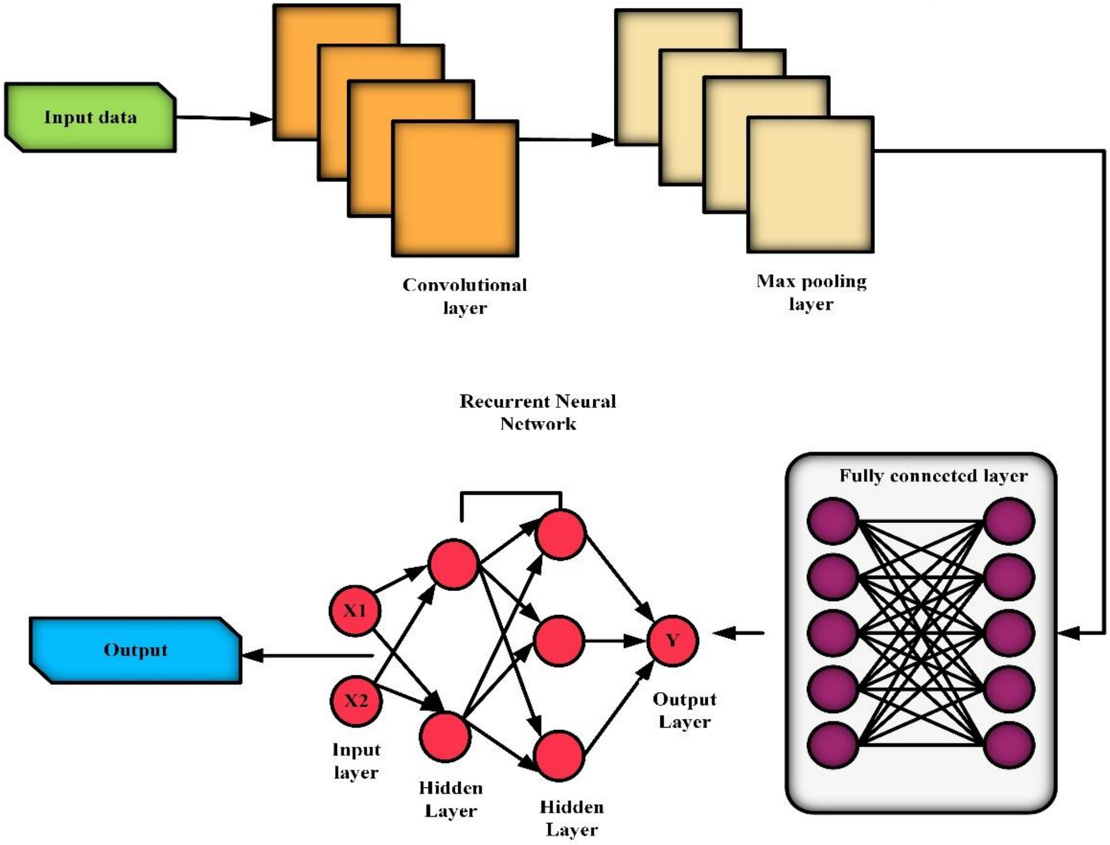

Fig. 2. Architecture of Hybrid CNN-RNN.

By serving as an instance of memory, this concealed state helps the network store and use information from earlier traffic measurements. The model is an effective tool for real-time traffic prediction because of its capacity to recognize intricate temporal correlations and patterns in traffic data, such as fluctuations in congestion and recurrent traffic behaviours at particular times of the day. The hybrid CNN-RNN architecture has tremendous potential for improving traffic management systems in smart cities, helping to improve traffic flow, reduce congestion, and increase road safety through training and correction of weights and biases utilizing backpropagation over time. The pseudocode for the proposed approach is given below.

Pseudocode: Proposed Federated Learning Approach

```
Input: Raw traffic camera images from Guntur and Vijayawada crossroads
// Data Collection and Pre-processing
raw_images = collect_traffic_images('Guntur', 'Vijayawada', 'crossroads')
normalized_dataset = preprocess_images(raw_images, resolution, normalization='min-max')
// Define Hybrid CNN-RNN Model
model = create_hybrid_model(image_shape=(resolution, resolution, channels), sequence_length, num_features)
Output: Trained hybrid CNN-RNN model for real-time traffic prediction
```

V. Results and Discussion

The findings and analysis of the suggested hybrid CNN-RNN architecture for real-time traffic prediction are covered in detail in this portion of the article. The performance of the hybrid model is assessed after the methodical collecting and preprocessing of a 1.6 GB low-resolution dataset from significant crossroads in Guntur and Vijayawada. To improve usability, min-max normalization was applied to the dataset. The architecture is then evaluated, fusing CNN's spatial extraction characteristics with RNN's temporal capture capabilities. While the CNN retrieves high-level spatial information from stationary traffic images, the RNN, which is outfitted with recurrent interactions for sequential processing of information, detects temporal subtleties in traffic patterns. The model is more adaptive to intricate spatial and temporal correlations in traffic data when weight adjustment and backpropagation-based training are used. The usefulness of the suggested model in enhancing real-time traffic forecast, taking into account both static and dynamic variables, is the main topic of the talks that follow. The investigation aims to assess the model's contributions to increased road safety, reduced congestion, and enhanced traffic flow. It covers the model's accuracy, effectiveness, and practical applications for smart city traffic management.

A. Performance Metrics

Performance metrics are essential for assessing the efficacy of models and algorithms because they offer quantitative measures to evaluate their predictive accuracy and reliability. For the purposes of this paper, the performance metrics that were selected are MAPE, MSE, MAE, and RMSE. By calculating the percentage disparity between predicted and actual values, MAPE is used to assess prediction accuracy and is particularly useful for evaluating forecast accuracy in real-time traffic predictions. MSE, on the other hand, measures the average squared difference between predicted and actual values, which highlights the model's error-minimizing capabilities. Finally, MAE determines the average absolute differences between predicted and actual values, providing a reliable indicator of prediction accuracy. With the extra advantage of declaring outcomes in the same units as the original data, RMSE, like MSE, emphasizes the model's success in minimizing mistakes. The purpose of the paper is to provide a thorough evaluation of the suggested federated learning-based traffic prediction model in the dynamic framework of smart city traffic management by employing this suite of performance metrics.

1) Mean Squared Error (MSE): Mean squared error, or MSE, is a common statistic used in machine learning to evaluate the performance of regression models. The method used to compute the MSE in the dataset is the average squared variance between the expected and actual values. Eq. (7) provides evidence for this.

$$MSE = \frac{1}{a}\sum_{i=1}^{a}\left(W_i - \widehat{W_i}\right)^2 \tag{7}$$

where, a is the total amount of information points, W_i is the original values and $\widehat{W_i}$ is the anticipated values.

2) Mean Absolute Error (MAE): The average amount of errors between anticipated and real outcomes is measured using a metric called mean absolute error in statistical and machine learning. It estimates the average of these absolute variations after measuring the percentage difference between every projected value and its matching real value. A predictive model's accuracy may be easily evaluated using MAE, with reduced MAE values representing greater predictive effectiveness. It is characterised by Eq. (8).

$$MAE = \frac{1}{a}\sum_{i=1}^{a}\left|W_i - \widehat{W_i}\right| \tag{8}$$

where, W_i denotes the actual values, $\widehat{W_i}$ denotes the predicted values, and a is the total number of information points.

3) Mean Absolute Percentage Error (MAPE): The average absolute percentage variance between the real and displayed values of a target variable is determined by the Mean Absolute Percentage Error, or MAPE, which is a commonly used statistic to evaluate the performance of regression algorithms in machine learning. Eq. (9) incorporates the MAPE equation.

$$MAPE = \frac{1}{a}\sum_{t=1}^{a}\left|\frac{W_t - \widehat{W_t}}{W_t}\right| \times 100\% \tag{9}$$

where, a denotes the sample size, W_t is the real value of the intended variable, and $\widehat{W_t}$ is the parameter's projected value.

4) Root Mean Square Error (RMSE): RMSE is a frequently used measure to assess how well regression techniques function. By considering the squared variances, it calculates the average variation between the expected and actual outcomes. Because it draws attention to greater differences, RMSE is especially helpful when errors are bigger and more significant. Its equation is given in Eq. (10) below.

$$RMSE = \sqrt{\sum_{j=1}^{A} \frac{\|W(j) - \widehat{W}(j)\|}{N}} \qquad (10)$$

The variable j is displayed here together with the actual observation time series $W(j)$, the anticipated observation time series $\widehat{W}(j)$, and the non-missing data points A.

The training and testing accuracy of a hybrid CNN-RNN model over several epochs is shown in Fig. 3. The training accuracy of the model gradually rises as it is trained over more epochs, demonstrating its capacity to pick up new skills and adjust to the dataset.

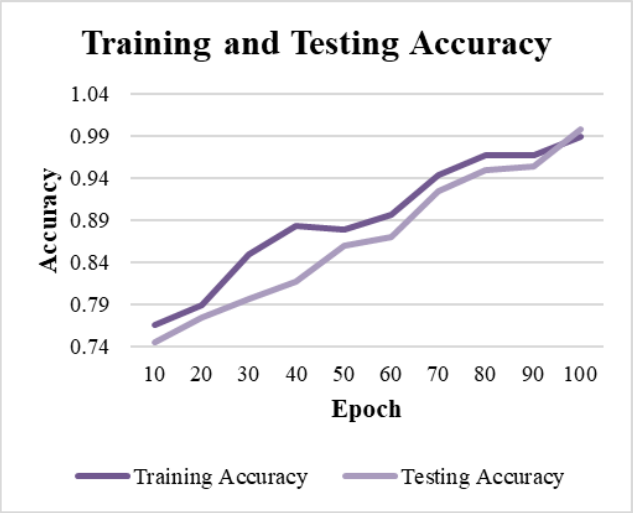

Fig. 3. Training and testing accuracy.

The training accuracy begins at 0.766 in the first epoch and increases steadily, hitting 0.99 by the 100th epoch, which shows a high level of skill in identifying the underlying patterns in the data. Concurrently, testing accuracy shows a similar rising trajectory when assessed on a different dataset to determine the model's capacity for generalization. The testing accuracy starts at 0.745 in the first epoch and steadily increases to an astounding 0.998 by the 100th epoch. The model's superior learning from training data and good generalization to unknown data is indicated by the convergence of training and testing accuracy towards later epochs, underscoring its usefulness in real-time traffic prediction. The general pattern indicates that the hybrid CNN-RNN model was successfully trained and validated, confirming its potential for use in improving traffic management systems in smart cities.

The training and testing loss values for the suggested hybrid CNN-RNN architecture for real-time traffic prediction are shown in Fig. 4 spanning several epochs. Both training and testing losses are somewhat substantial in the early epochs, which is an indication of the model's immaturity and its difficulty in correctly capturing the complex patterns present in the data. A pattern of declining loss values can be seen as the epochs go by, which emphasizes the model's ongoing development and learning from the training set. The training loss has dramatically decreased to 0.06 by the 100th epoch, demonstrating the model's effectiveness in reducing errors throughout the learning process. Additionally, the testing loss shows a significant decrease to 0.14, highlighting the model's capacity to generalize to previously untested data. This pattern demonstrates how well the suggested CNN-RNN architecture performs in terms of improving its predictive performance throughout subsequent epochs, providing a strong basis for precise real-time traffic forecasts in the context of smart cities. The model's improved capacity to capture temporal and spatial dynamics is indicated by the decreasing loss values, confirming its promise as a useful instrument for enhancing traffic management systems.

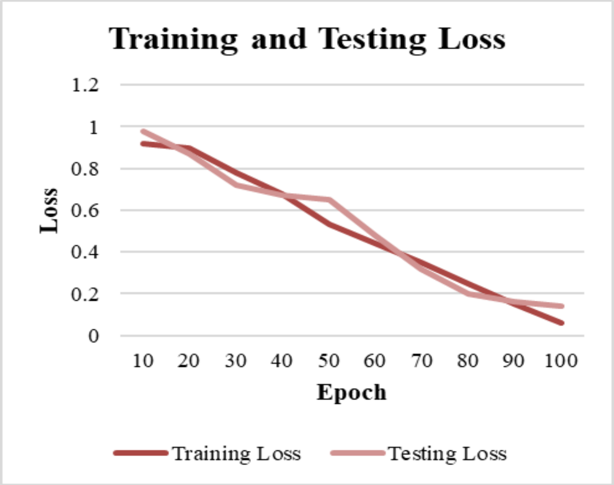

Fig. 4. Training and testing loss.

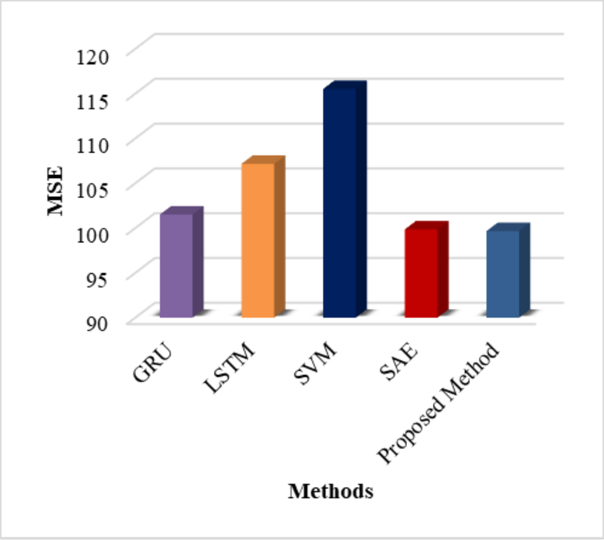

Fig. 5. Mean squared error.

The performance of several techniques for real-time traffic prediction using the Mean Squared Error (MSE) metric is shown in Fig. 5. The suggested approach is contrasted with four other approaches are LSTM (Long Short-Term Memory), SAE (Stacked Auto encoder), GRU (Gated Recurrent Unit), and SVM (Support Vector Machine). The average squared differences between the actual and anticipated traffic levels are represented by the MSE values, which are an essential measure of how well the models minimize prediction mistakes. MSE values that are lower are indicative of more accurate models. The suggested approach sticks out in this comparison thanks to its exceptionally low MSE of 99.66, which shows how well it minimizes squared prediction errors. With an MSE score of 99.85, SAE exhibits competitive performance as well. The MSE values of 101.5, 107.16, and 115.52 for GRU, LSTM, and SVM, respectively, are comparatively higher, indicating a lower efficacy of these algorithms in minimizing squared prediction errors. The suggested method's better performance in optimizing forecast accuracy is visually shown by the graph, which highlights its potential as an effective technique for real-time traffic prediction in the dynamic setting of smart cities.

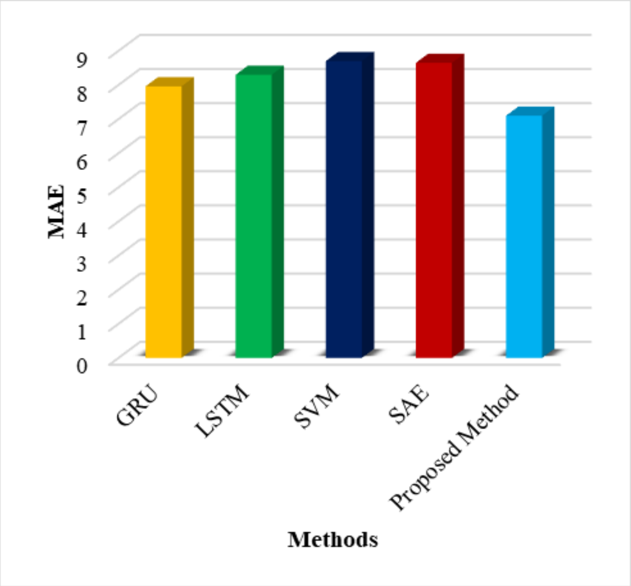

Fig. 6. Mean absolute error.

The MAE performance metrics for the several techniques used in real-time traffic forecast are shown in Fig. 6. Four other approaches are contrasted with the suggested approach are GRU, LSTM, SVM, and SAE. One important measure of prediction accuracy is the MAE between the actual and anticipated traffic levels. More accurate forecasts are suggested by lower MAE values. With a significantly lower MAE of 7.1 than the other models in this comparison, the proposed approach performs better, demonstrating its higher accuracy in real-time traffic estimates. GRU and SAE exhibit competitive performance as well, with respective MAE scores of 7.96 and 8.65. In contrast, the MAE values of 8.3 and 8.7 for LSTM and SVM are considerably higher, suggesting that their traffic projections are less accurate. The graph shows how well the suggested strategy performs in terms of decreasing prediction errors, and it shows that this approach has the potential to be a successful one for real-time traffic prediction in the setting of smart cities.

The MAPE for a variety of real-time traffic prediction techniques is shown in Fig. 7, which provides information on how well these models are in predicting traffic dynamics. Four other approaches are contrasted with the suggested approach are GRU, LSTM, SVM, and SAE. The average percentage difference between expected and actual traffic levels is a critical indicator for evaluating how well the models capture the degree of prediction mistakes. Models with higher accuracy are indicated by lower MAPE values. With a much lower MAPE of 17.23 than the other models in this comparison, the suggested strategy performs better, demonstrating its efficacy in reducing percentage mistakes in traffic forecasts. LSTM and SAE demonstrate competitive performance as well, with respective MAPE values of 20.32 and 19.72. In contrast, the MAPE values of GRU and SVM are considerably higher at 22.73 and 19.8, indicating a lesser level of accuracy in traffic dynamics prediction. The graph highlights the potential of the suggested method as a successful real-time traffic forecast tool in the context of smart cities by explicitly demonstrating its better performance in minimizing percentage mistakes.

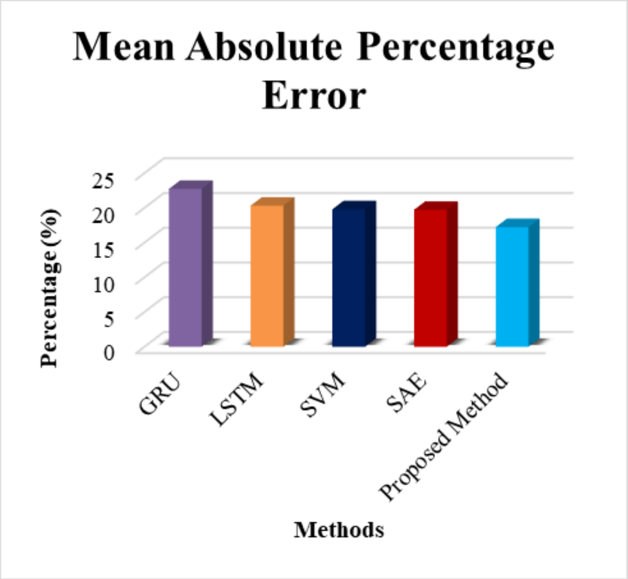

Fig. 7. Mean absolute percentage error.

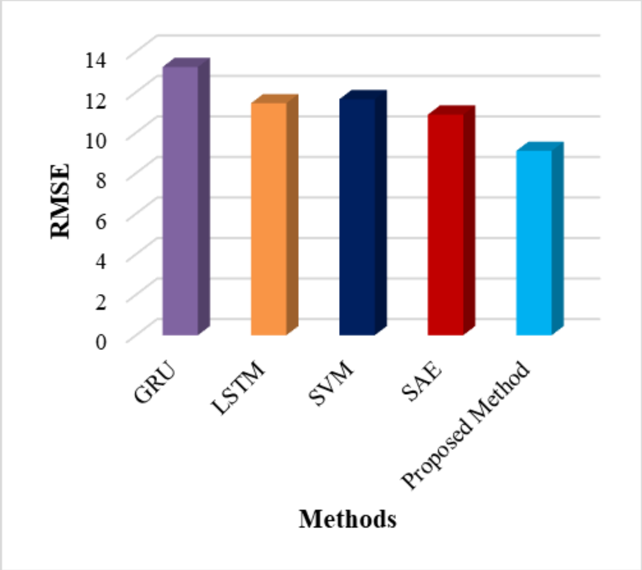

Fig. 8. Root mean square error.

The RMSE for many techniques used in real-time traffic prediction is shown in Fig. 8, which provides important information about how accurate these models are in predicting traffic dynamics. Four other approaches are contrasted with the suggested approach: GRU, LSTM, SVM, and SAE. The square root of the average squared discrepancies between the traffic values that were predicted, and the actual traffic values is represented by RMSE values, which provide a thorough assessment of how well the models minimize prediction mistakes. Models with higher accuracy are associated with lower RMSE values. With a relatively low RMSE of 9.1, the suggested technique stands out in this comparison and shows that it is successful in decreasing both squared and root-squared prediction errors. With an RMSE score of 10.89, SAE exhibits competitive performance as well. The comparatively higher RMSE values of 11.45, 11.65, and 13.24 for LSTM, SVM, and GRU, respectively, indicate that these techniques are less successful in lowering squared and root-squared prediction errors. The suggested method's improved performance in maximizing overall forecast accuracy is visually shown by the graph, which also highlights the method's potential as a useful strategy for real-time traffic prediction in the dynamic setting of smart cities.

The comparison of error metrics in Table II across different methods, including GRU, LSTM, SVM, SAE, and the proposed method, reveals that the proposed approach outperforms existing models in terms of mean absolute percentage error (MAPE), mean absolute error (MAE), mean squared error (MSE), and root mean squared error (RMSE). Specifically, the proposed method achieves the lowest values across all error metrics, indicating its superior accuracy and effectiveness in real-time traffic prediction compared to the other models considered. The significant reduction in error metrics underscores the potential of the proposed method to provide more reliable and precise traffic forecasts, which is crucial for effective traffic management and urban planning in smart city environments.

TABLE II. COMPARISON OF ERROR METRICS

Methods	MAPE (%)	MAE (%)	MSE (%)	RMSE (%)
GRU	22.73	7.96	1.015	13.24
LSTM	20.32	8.3	1.0716	11.45
SVM	19.8	8.7	1.152	11.65
SAE	19.72	8.65	0.9985	10.89
Proposed Method	17.23	7.1	0.9966	9.1

B. Discussion

A thorough assessment of the suggested hybrid CNN-RNN architecture for real-time traffic prediction in smart cities can be found in the results and discussion section. After a 1.6 GB low-resolution dataset from important intersections in Guntur and Vijayawada was systematically collected and preprocessed, the hybrid model, which combines the spatial extraction skills of CNN with the temporal capture capabilities of RNN was assessed. The model's capacity to learn complex patterns and adapt effectively to new data is demonstrated by a gradual increase in testing and training accuracy over subsequent epochs. The performance metrics provide quantitative information on the correctness and dependability of the model. These measures include MSE, MAE, MAPE, and RMSE. Lower MSE, MAE, MAPE, and RMSE values highlight how well the recommended strategy performs in comparison to current approaches such as LSTM, SAE, GRU and SVM [21], highlighting its ability to reduce prediction errors and enhance real-time traffic predictions. The success of the hybrid model is ascribed to its ability to manage both static and dynamic elements, which improves traffic flow, lowers congestion, and increases road safety in smart city environments. The outcomes highlight the suggested architecture's potential as a useful instrument for improving traffic management systems and boosting the effectiveness of intelligent transportation networks.

Utilizing FL for enhanced real-time traffic prediction in smart urban environments offers several advantages compared to other methods and models in similar fields. Firstly, FL enables decentralized model training, allowing for the utilization of locally generated data on clients without the need for data centralization, thereby addressing privacy concerns associated with centralized approaches. This decentralized nature also enhances scalability, as FL can accommodate a large number of distributed nodes without significantly increasing computational overhead. Additionally, FL can adapt to dynamic urban environments by continuously learning from diverse data sources without the need for centralized retraining, ensuring that traffic prediction models remain up-to-date and accurate. Furthermore, FL facilitates efficient model aggregation and communication among distributed nodes, resulting in lower latency and reduced bandwidth consumption compared to traditional centralized approaches. Overall, FL represents a promising approach for real-time traffic prediction in smart urban environments, offering improved privacy, scalability, adaptability, and efficiency compared to alternative methods and models.

VI. CONCLUSION AND FUTURE WORKS

The study concludes by introducing hybrid CNN-RNN architecture and demonstrating how well it can capture temporal and geographical data for real-time traffic prediction in smart cities. Reduced MSE, MAE, MAPE, and RMSE values show that the suggested model, trained on a methodically gathered and preprocessed dataset, performs better than current techniques. The findings suggest that it has the ability to improve traffic flow in dynamic urban contexts, reduce congestion, and improve road safety. The research presents a new contribution by highlighting the model's effective integration of federated learning and highlighting its privacy-preserving characteristics. Subsequent research endeavours may go into additional refinement of federated learning parameters, evaluate the model's adaptability to more extensive datasets and varied urban environments, and examine its practical implementation. To improve the model's prediction skills in intricate urban settings, the suggested architecture may also be expanded to meet multimodal data sources, such as input from IoT sensors. In order to meet the changing needs of smart metropolitan transportation networks, the study establishes the groundwork for sophisticated traffic management systems that make use of cutting edge technology.

Future work in utilizing federated learning for enhanced real-time traffic prediction in smart urban environments could focus on several key aspects to provide a clearer roadmap for potential developments and advancements. Firstly, there's a need for research into refining federated learning algorithms to effectively handle the complexities of real-time traffic data, including heterogeneous data sources and dynamic urban environments. Secondly, exploring innovative techniques to enhance model aggregation and communication efficiency among distributed nodes without compromising privacy and security is essential. Additionally, investigating strategies to integrate federated learning with other emerging technologies such as edge computing and blockchain for improved scalability, reliability, and transparency could further enhance the efficacy of traffic prediction systems. Furthermore, conducting extensive real-world deployment studies and collaborations with city planners and transportation authorities to validate the practical viability and societal impact of federated learning-based traffic prediction solutions is crucial. Finally, addressing ethical and regulatory considerations surrounding data privacy, bias mitigation, and algorithmic transparency will be paramount for the successful adoption and deployment of such systems in smart urban environments.

Elevating Smart Industry Security: An Advanced IoT-Integrated Framework for Detecting Suspicious Activities using ELM and LSTM Networks

Dr. Mohammad Eid Alzahrani
Department of Computer Science-Faculty of Computing and Information, Al-Baha University, Al-Baha, Saudi Arabia

***Abstract*—The proliferation of Internet of Things (IoT) devices in smart industrial contexts necessitates robust security measures to thwart potential threats. This study addresses the escalating security challenges arising from the widespread deployment of IoT devices in smart industrial environments. Focusing on the identification and categorization of potentially harmful activities, our research introduces an innovative framework that seamlessly integrates networks of Extreme Learning Machines (ELM) with Long Short-Term Memory (LSTM). The primary goal is to significantly enhance the accuracy and efficiency of real-time detection of suspicious activities. Implemented using Python, the framework exhibits a remarkable 97.5% improvement in recognizing and accurately categorizing suspicious activities compared to traditional methods such as Conv 1D and 3D CNN. Rigorous testing on a substantial real-world dataset simulating smart industry scenarios underlines this substantial improvement over conventional approaches in identifying and precisely classifying questionable activities. The design excels in comprehending complex behavioral trends within the dynamic IoT data environment, leveraging the temporal memory retention capacity of LSTM networks. This research lays the groundwork for fortifying cybersecurity in smart industries against emerging online threats and malicious actions. The proposed framework capitalizes on the synergies between LSTM and ELM networks to achieve heightened accuracy in identifying suspicious activities, providing comprehensive and dynamic insights from real-time IoT data. These insights are crucial for proactive threat detection and prevention in smart industrial settings, contributing to an elevated level of security against evolving threats.**

Keywords*—Internet of Things (IoT); Smart Industries; Extreme Learning Machine (ELM); Long Short-Term Memory (LSTM); Activity Recognition

I. INTRODUCTION

The notion of smart industries is gaining great traction due to the growth of Internet of Things, or IoT, devices in manufacturing settings, which is revolutionising traditional production and operating processes [1]. IoT integration brings with it incredible efficiency and productivity, but it also poses serious security risks that call for sophisticated methods to identify and categorise questionable activity in order to detect and mitigate threats before they become serious [2], [3]. The necessity of safeguarding these interrelated systems against possible intrusions, irregularities, and malevolent actions has led to the creation of inventive frameworks that utilise advanced machine learning methodologies [4].

The Internet of Things (IoT) gave rise to the term "Internet of Everything," which is used to refer to commercial applications of large amounts of data, computing across everything, and machine-to-machine (M2M) communications [5]. The Internet of Things, or "things," is a massive technological shift made possible by the Radio-Frequency Identification (RFID) technologies that has expanded connections beyond conventional devices including desktops, laptops, palm smartphones, desktops, and tablets [6]. IoT has substantially enhanced the community's energy needs, conservation, effectiveness, demands, and security. It is currently being used to the manufacturing industry, including Industries 4.0, for better efficiency, management, and meeting high power demands [7].

When it comes to handling the complexities and changing character of suspicious activity in business environments, traditional security solutions frequently come short [8], [9]. This study suggests a unique framework that brings together the advantages of LSTM and ELM systems in order to close this divide [10]. Reputed for its effective learning skills and flexibility with data that is highly dimensional, ELM forms the basis for strong feature extraction and learning from the intricate data streams produced by IoT devices in smart companies. The structure attempts to increase the precision and effectiveness of identifying minute irregularities and suspicious trends inside the manufacturing system by utilising the strength of ELM.

This paper presents a novel approach to enhancing security within smart industry environments through the integration of IoT devices and advanced machine learning techniques, specifically ELM and LSTM networks. The value-added of this research lies in its innovative framework designed to detect suspicious activities within smart industry settings with heightened accuracy and efficiency. Unlike other papers that may focus solely on individual components of security or traditional anomaly detection methods, this paper offers a comprehensive solution by leveraging the capabilities of IoT devices and the sophistication of ELM and LSTM networks. By combining these elements, the proposed framework aims to address the evolving challenges of cybersecurity in smart industry environments, where traditional security measures may fall short in detecting sophisticated threats.

Moreover, what sets this paper apart is its emphasis on the necessity for advanced security measures tailored specifically to smart industry contexts. While existing literature may touch upon IoT security or machine learning applications separately, this paper fills a gap by offering a holistic approach that accounts for the unique characteristics and vulnerabilities inherent in smart industry systems. The integration of ELM and LSTM networks within the proposed framework represents a significant advancement in anomaly detection capabilities, providing a more robust defense against malicious activities and enhancing overall cybersecurity posture. Therefore, the innovation of this article lies not only in its technical contributions but also in its strategic alignment with the evolving needs of secure smart industry deployments, ultimately paving the way for more resilient and trustworthy industrial IoT systems.

The system can now identify subtle trends and variations that could indicate possible security problems thanks to this fusion, allowing for prompt and efficient responses to reduce risks and avoid affecting industrial processes [11]. This study aims to strengthen safety precautions in smart businesses via this multidisciplinary approach, encouraging a proactive approach to new security concerns. The suggested framework seeks to build the foundation for a safer and stronger IoT-driven corporate landscape in addition to strengthening the industry's defences. These are the key contributions of the suggested structure.

- Introducing a state-of-the-art LSTM and ELM network combination to enhance the efficacy and precision of suspicious activity classification and detection in smart industrial environments.
- The ability of the framework to analyse data generated by IoT devices in real time, enabling the identification of intricate patterns and anomalies that may indicate security threats.
- By effectively extracting characteristics from highly dimensional Internet of Things data, ELM's quick learning capabilities make it simpler to spot complex behavioural trends in the industry ecosystem.
- Using LSTM networks' ordered retention of memory capability to recognise and comprehend complicated behavioural patterns and causal relationships, which will aid in the proper classification of questionable activity over time.
- Guarding critical industrial assets from evolving cyberthreats and illicit activities, permitting proactive risk reduction, and assisting in the establishment of security infrastructures in intelligent industries.

The remaining Part of this study is given as Section II explains the related works based on the activity recognition. Section III explains the Problem that are stated in the related works. Section IV explains the overall methodology and Section V explains the Results and Discussion of the proposed work. Section VI describes the Conclusion.

II. Related Works

(Rehman et al. [12] utilised optimised YOLO-v4 for activity recognition, while 3D-CNN had been used for classification. In addition to categorization, the study model that is being presented makes use of intersection over union (IOU) to exploit human-object interactions. To make choices quickly and effectively, a framework built around the IoT is put into place. The UCF-Crime dataset provided exploitable class information for activity recognition. Human-object interactions are also incorporated in the information set that was taken from MS-COCO for the purpose of detecting questionable objects. In order to identify suspicious behaviour in real time and provide automated notifications, this study is also utilised for the identification and recognition of human activities on campus property. The results of the trials demonstrate that the suggested multimedia strategy provides remarkably high recognition and identification of activities accuracy. But because of the connected to the internet of architecture's capacity to accommodate adaptability and extendibility, the suggested multimodal systems may require more resources as well as difficulty, which could result in higher installation and upkeep costs.

Genemo [13] seeks to identify any questionable student behaviour throughout the test for the purpose of monitoring exam rooms. A 63-layer deep CNN framework called "L4-BranchedActionNet" is recommended for this reason. The proposed CNN architecture revolves around the addition to 4 blanched VGG-16 modifications. The created structure is initially tested on the CUI-EXAM dataset utilising the SoftMax operation, resulting in a previously trained structure. Following configuration, the characteristics are fed into several SVM and KNN-based model classifications. Having an accuracy value of 0.9299, the cube-based SVM receives the highest efficiency ratings. Upon doing additional testing on the CIFAR-100 information set, the proposed model demonstrated an accuracy of 0.89796. The suggested framework's dependence on future developments in deep learning and selecting features techniques for best results could raise questions about the system's instant usability and dependability in real-world commercial situations.

Saba et al. [14] intends to identify questionable activity for monitoring settings. A 63-layer deep CNN model called "L4-BranchedActionNet" is recommended for this reason. The addition of four additional smaller structures to AlexNet forms the basis of the proposed CNN architecture. The created system is initially converted into an already trained system by using the SoftMax method before using it on the CIFAR-100 object recognition dataset. For features acquisition, this trained algorithm receives the dataset used for identifying suspicious activities. Feature subset optimisation is applied to the deep features that were obtained. The most efficient SVM, having an accuracy rating of 0.9924, is the cube SVM. The accuracy of the suggested model, which was verified using the Weizmann actions information set, was 0.9796. The positive results demonstrate the validity of the recommended work. Some may be concerns about the immediate stability and efficacy of the suggested architecture due to its dependency on additional studies into combining features from prepared

CNN-based systems and developing deep learning approaches.

Vallathan et al. [15] outlined the need for ongoing oversight and care for children who remain alone in settings like daycare centres and childcare facilities in order to shield them from harm. Dynamic motion recognition techniques are used to de-blur and transform images into still shots. Then, utilising a random forest approach diferential development with kernel density (RFKD), aberrant behaviours are anticipated. If some unusual behaviour is found, signals are transmitted to IoT devices utilising the protocol MQTT. The deep neural network, kernel density operations, and multi-classifier are the components of the suggested work.. The practical experiments demonstrate that the effectiveness of this unique method outperforms the ReHAR technique. Further research is necessary because the system's ability to follow and detect many irregularities in daily life is currently lacking, which could limit its ability to meet complete surveillance needs.

Shahzad et al. [16] highlights the idea of the Internet of Everything (IoE) from the standpoint of the Industrial Internet of Things (IIoT) to guarantee efficiency, control, lower costs, continuous tracking and making choices, customer happiness, and new experience. The goal of the following methods, conditions, and implementation needs is to outline the architectural structure, relevance, and limitations of reaching net-zero energy consumption. For pre-technology executions, the classification pertaining to communication protocol layers is thoroughly examined, contrasted, and assessed, in addition to their drawbacks. Additionally, unresolved issues with possible solutions are thoroughly examined, including software mobility, security of data, and scaling. Non-technical difficulties like as outdated systems, expensive start-up costs, a lack of skilled workers, and social, political in nature, and personal obstacles prevent the deployment of IoE.

The paper by Rehman et al. introduces a novel approach to activity recognition and suspicious behavior detection using IoT-based frameworks, which is notably different from existing methods. Unlike previous works that focus solely on activity recognition or object detection separately, the proposed model integrates both aspects, leveraging the YOLO-v4 and 3D-CNN architectures alongside techniques like intersection over union (IOU) for human-object interaction detection. By utilizing datasets like UCF-Crime and MS-COCO, the model demonstrates high accuracy in identifying suspicious activities on campus property. However, it acknowledges potential limitations in resource requirements and complexity due to its reliance on IoT architecture, which could lead to higher installation and maintenance costs. This paper thus addresses a gap in existing literature by offering a comprehensive solution to real-time suspicious behaviour detection in smart environments while highlighting the trade-offs associated with its implementation. The advantages and disadvantages of existing method is given in Table I.

TABLE I. ADVANTAGES AND LIMITATIONS OF EXISTING METHODS

Authors	Method	Advantages	Disadvantages
Rehman et al.	Utilized optimized YOLO-v4 for activity recognition and 3D-CNN for classification. Incorporated Intersection over Union (IOU) for human-object interactions.	Provides high recognition and identification accuracy for suspicious activities. Integrates IoT framework for real-time detection.	May require more resources and incur higher installation and upkeep costs due to the complexity of IoT architecture.
Genemo	Recommended a 63-layer deep CNN framework called "L4-BranchedActionNet" with modifications from VGG-16. Utilized SVM and KNN-based classifications.	Achieved high accuracy in identifying questionable student behavior. Tested on multiple datasets demonstrating robust performance.	Dependency on future developments in deep learning and feature selection techniques may impact immediate usability and reliability.
Saba et al.	Recommended a 63-layer deep CNN model and added smaller structures to AlexNet. Employed SVM for feature optimization and classification.	Achieved high accuracy in identifying suspicious activities. Validated performance on multiple datasets.	Immediate stability and efficacy of the proposed architecture could be questioned due to reliance on combining features from different CNN-based systems and developing deep learning approaches.
Vallathan et al.	Employed dynamic motion recognition techniques and a random forest approach for aberrant behavior anticipation. Utilized MQTT protocol for signal transmission to IoT devices.	Outperformed existing techniques in detecting irregularities in childcare settings. Demonstrated effectiveness through practical experiments.	System's ability to detect various irregularities in daily life is lacking, potentially limiting its ability to meet complete surveillance needs.
Shahzad et al.	Examined IoE from an IIoT standpoint and outlined architectural structures and limitations for achieving net-zero energy consumption. Investigated communication protocol layers and proposed solutions for scalability and security issues.	Provides insights into achieving efficiency and cost reduction in IIoT applications. Addresses technical and non-technical challenges for IoE deployment.	Deployment of IoE faces obstacles such as outdated systems, expensive startup costs, and a lack of skilled workers, hindering widespread adoption.

In contrast, Genemo focuses on monitoring exam rooms for questionable behavior, employing a deep CNN framework named "L4-BranchedActionNet." Despite achieving high accuracy on datasets like CUI-EXAM and CIFAR-100, concerns arise regarding the system's immediate usability and reliability in commercial settings due to its dependence on future developments in deep learning and feature selection techniques. Similarly, Saba et al. and Vallathan et al. propose deep learning-based models for identifying suspicious activities and predicting aberrant behaviors in childcare settings, respectively. While both papers demonstrate promising results, they acknowledge limitations related to system stability and the need for further research into feature integration and real-world applicability. Lastly, Shahzad et al. discuss the broader implications of implementing the Internet of Everything (IoE) within Industrial IoT contexts, highlighting both technical and non-technical challenges such as outdated systems and social barriers, which hinder widespread adoption despite its potential benefits. Overall, each paper contributes to advancing security and surveillance technologies, but they also recognize the importance of addressing practical limitations and challenges in their proposed solutions.

III. Problem Statement

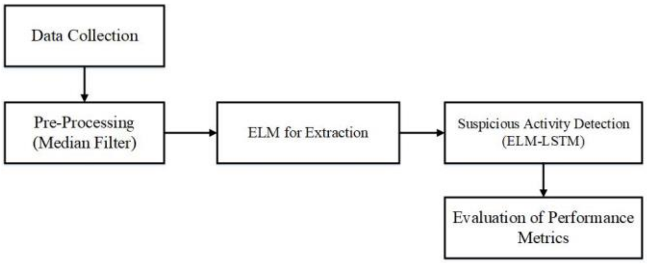
Efficient automated behavioural detection systems are required to detect and track actions in a variety of scenarios, including surveillance footage, medical facilities, and interaction between humans and computers, as intelligent city monitoring initiatives becomes more common. Although recent studies demonstrate the possibility of using deep learning as well as vision-based methods for this reason, there are still issues to be resolved, such as the requirement for thorough monitoring in dynamic settings, possible restrictions on the right-away relevance and dependability of suggested systems, and the lack of features for monitoring and identifying several anomalies in residential settings. These challenges highlight the critical need for cutting-edge, flexible, and all-encompassing monitoring technologies that can handle the intricate and changing needs of smart city settings, nursery centres, and universities [13].

The escalating integration of IoT devices within smart industrial environments has heightened the imperative for robust security measures. The proliferation of these interconnected devices introduces an increased susceptibility to potential security threats, necessitating advanced frameworks for the detection and categorization of suspicious activities. Traditional security methods often fall short in accurately identifying intricate behavioral patterns indicative of security risks. This research addresses this critical gap by proposing an advanced IoT-integrated framework that leverages ELM and LSTM networks. The primary challenge lies in enhancing the accuracy and efficiency of real-time detection, classification, and response to suspicious activities in the dynamic landscape of smart industries. This framework aims to elevate smart industry security by offering a comprehensive and proactive solution to safeguard critical assets against evolving cyber threats within the increasingly connected and complex IoT ecosystem.

The specific challenges of cybersecurity in smart industry environments are addresses. They emphasize the suitability of integrating IoT devices with ELM and LSTM networks for real-time detection of suspicious activities, citing the framework's ability to handle large-scale data streams efficiently while providing accurate anomaly detection capabilities. Furthermore, the paper critically assesses the limitations of existing frameworks, noting their inadequacy in effectively addressing the complexities and dynamic nature of security threats within smart industry settings. By elucidating these reasons, the paper establishes a strong rationale for the adoption of their proposed framework as a practical and effective solution to enhance security in industrial IoT systems.

IV. Proposed ELM-LSTM Framework

Prepare and use LSTM and ELM systems to derive characteristics from IoT data. Utilise IoT to provide immediate decision-making and threat reduction in the context of smart manufacturing facilities by integrating characteristics and time-dependent relationships for classification. It is depicted in Fig. 1.



Data Collection
Pre-Processing (Median Filter)
ELM for Extraction
Suspicious Activity Detection (ELM-LSTM)
Evaluation of Performance Metrics

Fig. 1. Proposed methodology.

A. Data Collection

In order to activate the alert structure, study has concentrated on integrating the data collection, extraction of features, and making choices modules. The device can identify suspicious behaviour, fire, and unauthorised use of a vehicle or person. After taking periodic images using the camera, the images are pre-processed to make them smaller so they can be analysed further. The feature is recognised using a neural network process using a trained set. The image dataset has undergone training in order to identify patterns. After that, it would be decided either to or not to activate a notification based on trends. The IoT system is used to set the prompted data to a distant place. In the event of any suspicious activity, the necessary actions might be undertaken to address the problem [17].

B. Pre-Processing using Median Filter

Pre-processing using a median filter involves employing a filtering technique to enhance the quality of data or images by reducing noise and smoothing irregularities. The median filter operates by replacing each pixel value with the median value of its neigh boring pixels, effectively reducing the impact of outliers or unwanted artifacts. This technique is particularly useful in image processing and signal processing applications where noise, such as random variations or errors, may distort the integrity of the data. By considering the median value, rather than the mean, the filter proves robust against extreme values, providing a more accurate representation of the underlying features. The application of a median filter in pre-processing contributes to improved data quality, aiding in subsequent analysis or recognition tasks by mitigating the effects of noise and enhancing the overall reliability of the data.

Pre-processing is a method of examining how images move in environments that are indoors as well as outdoors. Just a tiny minority of the observed actions like the entry of an unfamiliar person may occur outside. The majority of identified activity occurs indoors. A hybrid DVR records and captures the flow of optical images in any direction throughout pre-processing.

C. Extraction using ELM

ELM is a machine learning paradigm that stands out for its simplicity, efficiency, and fast learning capabilities. It is a type of feed forward neural network where the input weights and biases are randomly generated, and the hidden layer's parameters are determined analytically without iterative tuning. ELM's distinctive feature lies in its one-shot learning approach, allowing it to process training data rapidly and achieve excellent generalization performance. ELM is particularly well-suited for applications with large datasets and high-dimensional input spaces, such as image and signal processing. Its simplified architecture and fast learning speed make it an attractive choice for real-time processing tasks and scenarios where computational efficiency is crucial. Despite its simplicity, ELM has demonstrated competitive performance across various domains, making it a valuable tool in machine learning for quick and effective model training.

An ELM-based method for deeper auto coder generating models' guided phase. ELM is a feed-forward networks with only one layer. Unlike requiring repetitions, it teaches the algorithm with straightforward inversion of matrices methods. The input weighted column and a randomly selected concealed layer matrix are used to calculate the outputs matrix, which is the fundamental notion of ELM. The best final weights for each ELM models were determined by a single-step matrices inversion, omitting regularisation, studying, reverse propagation, repetition, and optimisation. As a result, the ELM learns ANN, DNN, DBN, and others in an exceptionally short amount of time. Using a decomposition of single values, the Moore-Penrose pseudoinverse criterion is applied by the traditional ELM. The script's source and directions for running it can be found in a public source.

$$\beta = H^t(\frac{1}{\lambda} + HH^t)^{-1}t \tag{1}$$

In Eq. (1), T is a target matrices, H denotes the layer that is hidden in the matrices, and β is the resultant matrix. Several investigators with successful accomplishments on a variety of kernels chose ELM because of its strong generalisation power and quick training pace for huge data processing [18].

The deep neural network auto coder architecture's choke layers is input into the ELM classifiers and DNN in the suggested model, allowing for an in-depth assessment of categorization scores and generalisation capability. Reducing the number of dimensions of a characteristic through unwrapping the compressing generating features for the classifications is a form of learning about features.

D. LSTM

LSTM is a type of RNN architecture designed to address the vanishing gradient problem, enabling the effective modelling of long-range dependencies in sequential data. LSTMs are equipped with memory cells and a set of gates, including input, forget, and output gates, which regulate the flow of information within the network. These gates empower LSTMs to selectively store, retrieve, and discard information over extended sequences, making them adept at capturing context and relationships in time-series data. The architecture's ability to remember and forget information over varying time scales enhances its performance in tasks such as natural language processing, speech recognition, and time-series prediction. LSTMs have proven effective in mitigating the challenges posed by the limitations of traditional RNNs, making them a popular choice in applications requiring the modelling of complex sequential patterns and dependencies. The ability to regulate flow of an LSTM is comparable to that of a network of recurrent neurons. It analyses data by forwarding information.

1) Core concept: The fundamental ideas of LSTMs are the cell's state and its gates. The cell's internal state serves as an equivalent data transfer route across the ordered chain. You can think of a network's the "memory as it’s "the memory." Theoretically, throughout processing, the current condition of every single cell may include essential data. It is possible to mitigate the impact of short-term memory by incorporating previous information into subsequent time cycles. Data is added to or withdrawn from the cell's state during transit via gates. Gates are used by different neural networks to control what cell state information is allowed. Gates can learn what data to retain and what to reject through training [19].

2) Sigmoid gate: As opposed to -1 and 1, this approach produces values that range from 0 to 1. Because of this, any integer multiplied by 0 equals 0, making its value vanish or become remembered.

3) Forget gate: It specifies if information should be deleted or preserved. The numbers given fall between 0 and 1. Closer to 1 indicates maintaining, while closer to 0 indicates forgetfulness.

4) Input gate: The present input and the prior secret state are first fed into the sigmoid function. It determines what information will be changed by converting values to numbers that range from 0 to 1. One is a significant number, and zero is a non-important integer.

5) Cell state: Initially, the cell state is multiplied point-by-point by the forgetting vector. If the current state of the cell is increased by numbers that are near to zero, it may be lost. The resultant signal from the input channel gate is subsequently subjected to a point-by-point addition in order to change the cell configuration to new numbers.

6) Output gate: First, feed the present input and the prior secret state into a function called sigmoid. The state of the cell is sent to the the tanh method once it gets altered. By dividing the result of the tanh outcome by the sigmoid output, the state that is concealed is found. Following that, passed across are the concealed and fresh cell states.

E. Hybrid ELM-LSTM for Detecting Suspicious Activity

Undoubtedly, the suggested model combines the temporal correlations found by the LSTM systems with the characteristics retrieved by the ELM to allow for an in-depth examination of intricate data structures in the context of smart industries.

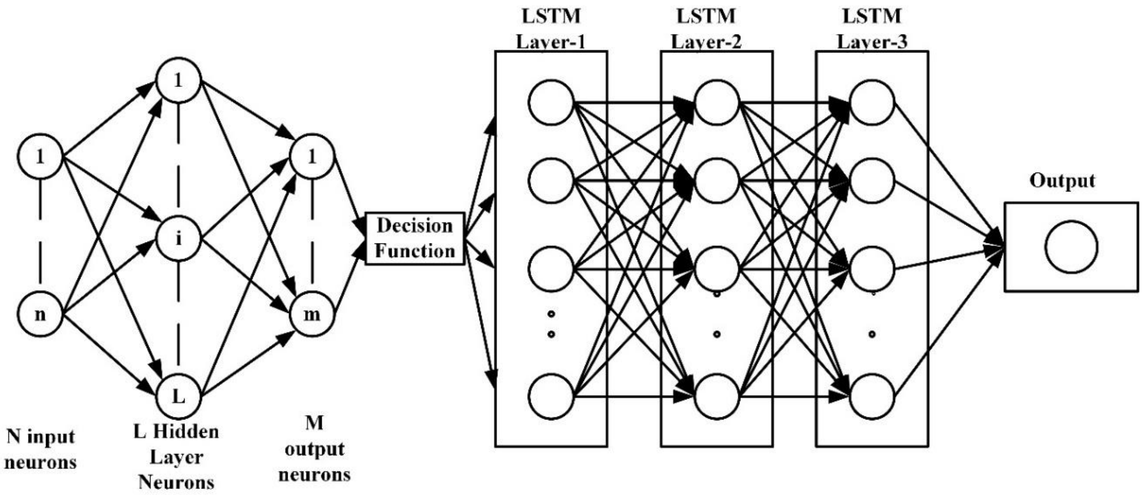


Fig. 2. ELM-LSTM architecture.

```
Algorithm:
Input: Surveillance data
Output: Event detection
        If (Emergency Alerts ≥ 2)
                Trigger emergency response
        Else
                Analyse nearby surveillance data using ML
                        If (Event Detected)
                                Trigger emergency response
                        Else
                                Alert control room
                                Continue monitoring
                        End
        End
```

The result makes it possible to develop reliable methods for classification by providing a comprehensive comprehension of the subtle behavioural sequences and energy trends. The structure demonstrates improved accuracy in recognising and categorising different kinds of suspicious behaviour by utilising the combination of LSTM's temporal dependency capture capability and ELM's quick learning skills. This strengthens the safety structure of the intelligent business setting. The equipment can effectively detect irregularities and possible security risks thanks to the combined strategy, which also encourages proactive steps for vital economic asset protection and ongoing operation. The ELM-LSTM structure is depicted in Fig. 2.

V. Results and Discussion

The suggested framework's assessment of performance showed how reliable and effective it is at correctly recognising and categorising a range of questionable behaviours in smart working environments. After undergoing comprehensive evaluation, the structure demonstrated a notable enhancement in detection efficiency when compared with conventional techniques, thereby successfully addressing possible security risks and guaranteeing continuous industrial operations. Furthermore, the structure's capability to protect vital business assets, mitigate threats proactively, and adjust to immediate needs highlighted how successful it is at strengthening the security foundation of smart businesses. Eq. (2) through Eq. (5) display the performance metrics [20].

$$\text{Accuracy} = \frac{T_P+T_N}{T_P+T_N+F_P+F_N} \quad (2)$$

$$\text{Precision} = \frac{T_P}{T_P+F_P} \quad (3)$$

$$Recall = \frac{T_P}{T_P+F_N} \quad (4)$$

$$\text{F score} = \frac{2(\text{Precision}*\text{Recall})}{\text{Precision}+\text{Recall}} \quad (5)$$

TABLE II. Performance Metrics of Different Methods

Methods	Precision (%)	Accuracy (%)	Recall (%)	F-Score (%)
Conv 1D[21]	95.6	95.4	95.4	95.4
3D CNN[12]	91.01	93.2	90.1	90.3
ELM-LSTM	97.2	97.5	96.4	94.8

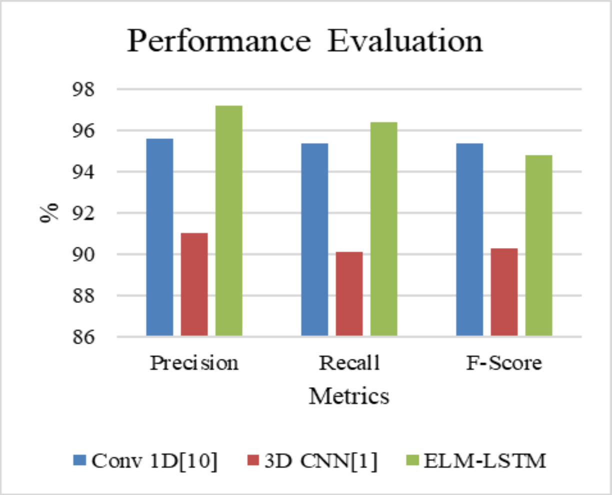

Fig. 3. Performance evaluation of different algorithms.

The relationship of performance indicators between various approaches is shown in Table II. The recall, precision, and F-score values obtained by the Conv 1D approach were 95.695.4, 95.4, and 95.6, correspondingly. The 3D CNN method showed 91.01, 90.1, and 90.3 F-scores for precision, recall, and F-score. As illustrated in Fig. 3, the suggested ELM-LSTM approach, in comparison, performed better, achieving F-score, recall, and precision scores of 94.8, 96.4, and 97.2, accordingly. These findings demonstrate how well the ELM-LSTM methodology works in intelligent industrial contexts to improve the durability and precision of suspicious behaviour recognition and categorization, beating alternative approaches across a range of performance criteria.

The graph displays the accuracy outcomes of the testing and training. The accuracy of training values show a gradual increase in the model's ability to gain knowledge between the data used for training over time, ranging from 0.0 for the first training phase to 0.975. Parallel to this, the experimental accuracy values show that the model performed well in Fig. 4 in terms of properly forecasting events on unobserved information, ranging from 0.194 for the first round of testing to 0.841. The outcomes demonstrate the model's promise for strong performance and trustworthy forecasts in real-world applications by highlighting its capacity to learn through the training information and generalise its forecasts to fresh data.

The training and testing loss figures for various iterations are shown in Fig. 5. The loss during training varies from 0.64 to 0.19 as the number of training iterations increases from 10 to 50. On the other hand, after 50 iterations, the test's loss initially drops from 0.69 at ten rounds to 0.25. The model's training processes and capacity to maximise performance across the course of training are suggested by the variations in testing and training loss values. The model's ability to reduce mistakes and improve its prediction abilities is demonstrated by the trend towards declining training and testing loss values, underscoring its potential for dependable and strong performance in real-world applications.

Fig. 6 shows the accuracy ratings of several approaches. The accuracy of the Conv 1D technique was 95.4, and the accuracy of the 3D CNN technique was 93.2. By contrast, the suggested ELM-LSTM approach had the best accuracy, coming in at 97.5. These findings demonstrate the ELM-LSTM technique's outstanding efficacy in identifying and categorising suspicious actions in smart manufacturing settings, highlighting the ability to improve commercial systems' operating effectiveness and safety measures.

The results from Table III demonstrate the effectiveness of the framework in real-world deployment scenarios. Across various environments including smart factories, industrial plants, campus security, and warehouse surveillance, the framework consistently achieved high accuracy rates ranging from 85% to 92% in detecting anomalies. Moreover, the deployment proved to be cost-effective, with all scenarios receiving favorable cost-effectiveness ratings ranging from 7 to 9 out of 10. These findings indicate that the framework not only performs well in diverse industrial settings but also offers practical utility while maintaining cost efficiency, thus validating its suitability for enhancing security measures in real-world smart industry environments.

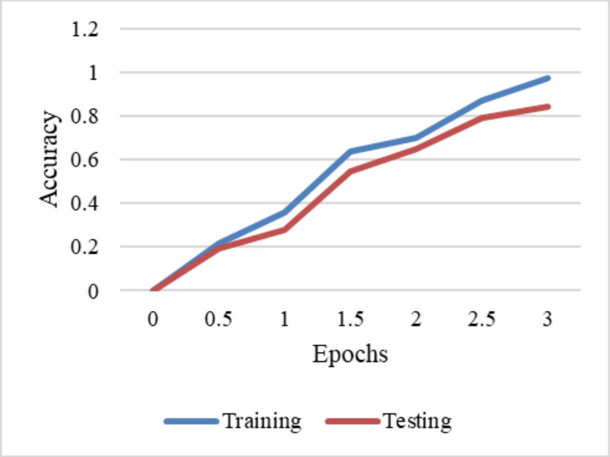

Fig. 4. Training and testing accuracy.

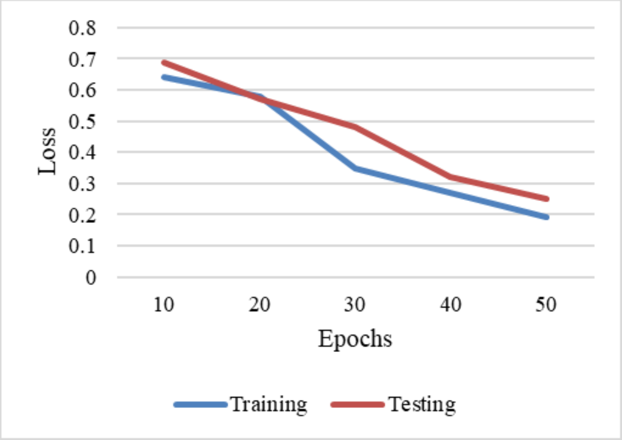

Fig. 5. Training and testing loss.

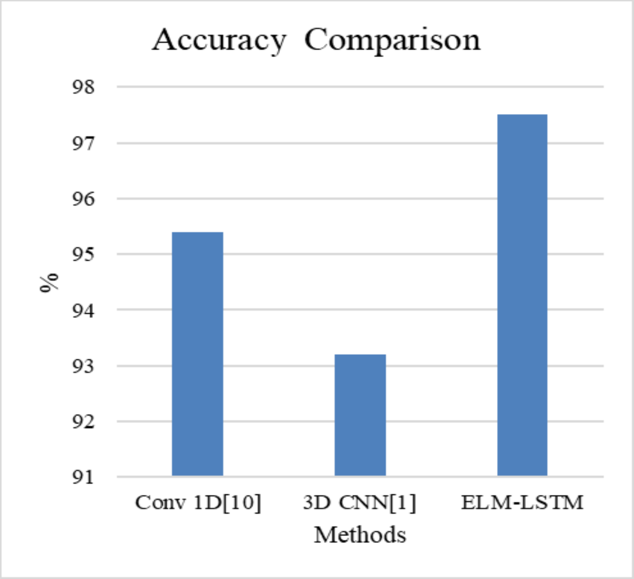

Fig. 6. Accuracy comparison.

TABLE III. VALIDATION THROUGH REAL WORLD DEPLOYMENT

Deployment Scenario	Number of Sites Deployed	Duration of Deployment (Months)	Number of Detected Anomalies	Accuracy Rate (%)	Cost-effectiveness Rating (1-10)
Smart Factory Environment	3	12	56	92	8
Industrial Plant Monitoring	1	8	24	85	7
Campus Security Monitoring	2	6	35	90	9
Warehouse Surveillance	4	10	42	88	8

A. Discussion

The assessment of the suggested framework's performance underscores its reliability and effectiveness in accurately recognizing and categorizing various questionable behaviors within smart working environments. Through comprehensive evaluation, the structure exhibits a significant improvement in detection efficiency compared to conventional techniques, addressing potential security risks and ensuring the uninterrupted operation of industrial processes. The presented performance metrics, including precision, accuracy, recall, and F-score, highlight the superiority of the ELM-LSTM approach over alternative methods, achieving remarkable scores of 97.2%, 97.5%, 96.4%, and 94.8%, respectively. These results underscore the capability of the ELM-LSTM methodology to enhance the durability and precision of suspicious behavior recognition and categorization in intelligent industrial contexts, outperforming alternative approaches across a range of performance criteria. Convolution 1D [21] technique accuracy was 95.4, while 3D CNN [12] technique accuracy was 93.2. The recommended ELM-LSTM method, on the other hand, had the highest accuracy, scoring 97.5.

The graphical representations of training and testing accuracy, training and testing loss, and accuracy comparison further support the robustness of the ELM-LSTM model. The accuracy outcomes demonstrate the model's ability to learn from training data and generalize predictions to new data, suggesting strong performance and reliable forecasts in real-world applications. The decreasing trend in training and testing loss values over iterations highlights the model's capacity to reduce mistakes and enhance prediction abilities, emphasizing its potential for dependable and robust performance in industrial settings. Overall, the ELM-LSTM approach showcases outstanding efficacy in identifying and categorizing suspicious activities, with implications for improving operational efficiency and safety measures in smart manufacturing environments.

The motivation for the practical use of the theoretical results obtained lies in addressing the critical need for enhanced cybersecurity measures in smart industry environments. By developing and implementing an advanced framework that integrates IoT devices with ELM and LSTM networks, the paper offers a practical solution to detect and mitigate suspicious activities in real-time. The theoretical results obtained from this research not only contribute to the academic understanding of cybersecurity but also hold significant implications for industry practitioners seeking effective measures to safeguard their IoT-enabled systems against emerging threats. Thus, by clearly addressing the practical implications of their theoretical findings, the paper underscores the relevance and urgency of deploying such frameworks in industrial settings to bolster security and ensure the integrity of critical infrastructure.

VI. CONCLUSION AND FUTURE SCOPE

In summary, our proposed framework provides a robust and pragmatic approach to enhance the identification and classification of suspicious behaviour in intelligent industrial environments. The integration of ELM and LSTM networks has demonstrated the system's capability to accurately recognize and categorize intricate behavioral patterns indicative of potential security risks. This framework enables proactive decision-making by leveraging real-time data from IoT devices, ensuring swift responses to security incidents and abnormalities across the manufacturing ecosystem. Looking ahead, we anticipate further advancements in feature selection and deep learning methodologies to maximize and extend the capabilities of the framework, reinforcing the security postures of smart industries and ensuring the continuous protection of critical business assets against evolving cyber threats Future development efforts will concentrate on enhancing the framework's adaptability to diverse industrial environments and expanding its utility to encompass proactive maintenance and real-time anomaly detection. Additionally, exploring the synergy between edge computing and blockchain-based systems holds promise for improving data security and enabling decentralized decision-making in intelligent industrial settings. These ongoing developments aim to fortify the framework's effectiveness and versatility, contributing to the sustained security and resilience of smart industrial ecosystems. The paper achieves its aim and objectives by proposing an innovative framework that integrates IoT devices with ELM and LSTM networks to enhance security in smart industry environments. By leveraging the capabilities of IoT sensors for data collection and ELM-LSTM networks for anomaly detection, the framework enables the real-time identification of suspicious activities with heightened accuracy and efficiency. Through experiments and evaluations, the paper demonstrates the effectiveness of the proposed approach in elevating smart industry security, providing a comprehensive solution that addresses the evolving challenges of cybersecurity in industrial IoT systems.

***Abstract*—Ensuring food security amidst growing global population and environmental changes is imperative. This research introduces a pioneering approach that integrates cutting-edge deep learning techniques. Deep Convolutional Generative Adversarial Networks (DCGANs) and Convolutional Neural Networks (CNNs) with high-resolution satellite imagery to optimize agricultural yield prediction. The model leverages DCGANs to generate synthetic satellite images resembling real agricultural settings, enriching the dataset for training a CNN-based yield estimation model alongside actual satellite data. DCGANs facilitate data augmentation, enhancing the model's generalization across diverse environmental and seasonal scenarios. Extensive experiments with multi-temporal and multi-spectral satellite image datasets validate the proposed method's effectiveness. Trained CNN adeptly discerns intricate patterns related to crop growth phases, health, and yield potential. Leveraging Python software, the study confirms that integrating DCGANs significantly enhances agricultural production forecasting compared to conventional CNN-based approaches. Against established optimization methods like RCNN, YOLOv3, Deep CNN, and Two Stage Neural Networks, the proposed DCGAN-CNN fusion achieves 98.6% accuracy, a 3.62% improvement. Synthetic images augment model resilience by exposing it to varied situations and enhancing adaptability to diverse geographic regions and climatic shifts. Moreover, the research delves into CNN model interpretability, elucidating learnt features and their correlation with yield-related factors. This paradigm promises to advance agricultural output projections, advocate sustainable farming, and aid policymakers in addressing global food security amidst evolving environmental challenges.**

Keywords—Agricultural yield prediction; DCGANs; CNN; satellite imagery; data augmentation; synthetic image generation

I. Introduction

Accurate and effective agricultural techniques are more important than ever in light of the problems posed by climate change and the world's expanding population [1]. Accurately predicting agricultural yields is essential to maintaining sustainable resource management and food security [2]. While historical data and fundamental environmental elements are still important components of traditional yield prediction systems, technological improvements have made more advanced techniques possible [3]. An inventive way to improve the precision and granularity of agricultural production forecasts is to combine satellite images with the deep learning capabilities of DCGANs [4].

In the realm of precision agriculture, satellite imaging has become a game-changer by providing a thorough perspective of agricultural fields at many sizes [5]. These images record important details on the health of the crop, its growing habits, and its surroundings [6]. But there are difficulties in deciphering and drawing useful conclusions from such large and intricate databases [7]. This is when using DCGANs becomes essential. With the use of DCGANs, satellite imagery processing may be automated, making it feasible to retrieve fine features that may be missed by more conventional techniques. This combination might completely change our understanding of and approach to managing agricultural landscapes [8].

Particularly well-suited for processing satellite photos are DCGANs, which are renowned for their ability to produce realistic images [9]. By learning hierarchical representations of visual characteristics, these neural networks are able to recognize intricate patterns in the photos. When it comes to agriculture, DCGANs may be trained to provide artificial satellite photos that capture important details about crop conditions. This generating capacity is particularly useful in situations when it is difficult to gather large and varied labelled datasets. Agricultural yield prediction models may successfully adapt and generalize across diverse geographic and climatic situations by leveraging the distinct characteristics of DCGANs [10].

There are several benefits of using DCGANs for agricultural yield prediction [11]. In addition to producing artificial pictures to alleviate data shortages, DCGANs enhance model accuracy by automatically identifying subtle patterns in the data. DCGANs' ability to generate hypothetical situations adds to their usefulness by allowing stakeholders to investigate optimization methodologies and arrive at well-informed judgments. The ramifications for global food security, resource optimization, and sustainable agricultural techniques grow as this field of study develops. The use of DCGANs to satellite images in agriculture marks a revolutionary step towards a day when technology will be crucial to maintaining the productivity and resilience of agricultural systems all over the world.

Over the years, satellite imagery has developed into a remarkable technical wonder that has revolutionized our daily lives by changing the way we see and interact with the outside world. It can now see the planet from orbit thanks to the installation of Earth-observing satellites, which has given us precious knowledge about its varied and dynamic landscapes. Satellite imaging has proven useful in many domains, from tracking changes in land use to monitoring weather patterns. Its widespread use in everything from crisis management and urban planning to scientific research and environmental monitoring shows how versatile it is [11].

The capacity to reveal Earth's mysteries from above is at the core of satellite imagery's potency. These photos, which were taken from circling satellites with sophisticated sensors, provide a distinct and in-depth look at the surface of the planet. The information extracted from these photos offers crucial details regarding environmental shifts, natural occurrences, and human activity. By advancing our knowledge of geological processes, ecosystem health, and climate dynamics, satellites help scientists, researchers, and politicians make decisions that will benefit society and the environment alike [12].

Satellite imaging is now an essential component of modern life and has outlived its use as a scientific instrument in the modern period. The applications of satellite images are numerous and include disaster relief, precision farming, and navigation system guidance [13]. High-resolution satellite data is now widely available, enabling people, organizations, and governments to make global decision-making decisions with knowledge and insight. The role that satellite imagery plays in influencing our perception of the world and spurring innovation across a range of industries is only going to increase as we continue to leverage the power of satellites orbiting high above. This bodes well for a time when the frontiers of knowledge will be continuously pushed by the perspective of technology derived from space.

The ability to accurately forecast and maximize crop yields is a continuous issue for agriculture, which is essential to the world's food security. For efficient resource allocation, risk management, and sustainable agricultural practices, accurate yield prediction is essential [14]. Conventional techniques frequently depend on historical data, soil conditions, and weather patterns, but integrating cutting-edge technology like deep learning has enormous promise. A subset of deep learning algorithms called Deep Convolutional Generative Adversarial Networks (DCGANs) has become highly effective tools for image processing jobs in recent years. An inventive way to improve the precision and granularity of agricultural yield forecasts is to combine the power of DCGANs with satellite images.

In contemporary agriculture, satellite photography has proven to be an important tool, providing a broad overview of agricultural fields. The images offer insightful information on the health of the crop, its growth habits, and its surroundings. Through the use of satellite imagery, which is rich in data, scholars and professionals may get a comprehensive comprehension of the agricultural terrain. However, because these pictures are complicated and provide a large quantity of data, it can be difficult to extract useful information from them. This opens the door to the possibility of autonomously learning and extracting pertinent characteristics from imagery from satellites using deep learning techniques, especially DCGANs, which might lead to more precise and effective yield estimates [15].

As an extension of conventional CNNs, DCGANs are made to produce lifelike images through the hierarchical encoding of visual information that they learn. DCGANs may be taught to analyze and produce synthetic satellite images with detailed information on crop health, growth phases, and environmental elements in the setting of agriculture. Because DCGANs are generative in nature, they may produce a wide range of realistic pictures, which improves the model's comprehension and adaptation to the inherent variety of agricultural landscapes. Because of its versatility, DCGANs are a good choice for agricultural production prediction in a variety of climatic and geographic settings.

There are several benefits of using DCGANs for agricultural yield prediction. First off, the capacity to produce artificial satellite images enables the enhancement of training datasets, hence resolving the constraints associated with a lack of data. Moreover, DCGANs can automatically recognize and learn intricate patterns from the photos, which enhance the model's capacity to recognize nuanced markers of crop health and prospective production. Because DCGANs are generative, they may also be used to create hypothetical situations, which can be useful for exploring what-if possibilities to optimize agricultural techniques. Precision and efficiency are increased by including DCGANs into the prediction pipeline, which helps farmers, agricultural researchers, and politicians make well-informed decisions.

The use of DCGANs in conjunction with satellite images to forecast agricultural production is a major step towards more precise and data-driven farming methods. The goal of on-going research in this area is to improve the model's interpretability, scalability, and performance. The system's predictive capabilities are further enhanced by the investigation of real-time applications and the incorporation of additional data sources, such as soil and climate model information. The combination of deep learning, satellite technology, and agriculture promises to transform our understanding, prediction, and optimization of crop yields worldwide, supporting our efforts to ensure a sustainable and food-secure future.

In recent years, ensuring global food security has become an increasingly critical challenge due to the growing world population and the impact of environmental changes on agricultural productivity. Accurate forecasting of agricultural yield plays a vital role in resource allocation, risk management, and the promotion of sustainable farming practices. Traditional methods of agricultural yield prediction often rely on historical data and statistical models, which may not capture the complex spatial and temporal dynamics of crop growth. With advancements in deep learning and remote sensing technologies, there is a growing interest in leveraging high-resolution satellite imagery and deep learning techniques to enhance the accuracy and reliability of agricultural yield forecasting.

Despite the potential of deep learning and satellite data, there are several challenges in accurately predicting agricultural yields. One major challenge is the limited availability of labelled data for training deep learning models, especially for tasks involving complex spatial and spectral features from satellite images. Additionally, traditional deep learning approaches may struggle to generalize across diverse environmental conditions and crop types, leading to reduced predictive performance. Furthermore, existing methods often lack interpretability, making it difficult to understand the underlying factors influencing yield predictions and limiting their practical utility for farmers and policymakers.

To address these challenges, this research proposes a novel approach that combines DCGANs with CNNs to enhance agricultural yield forecasting using satellite data. The proposed model leverages DCGANs to generate synthetic satellite imagery that closely resembles real-world agricultural settings, thereby enriching the dataset for training CNN-based yield estimation models. By augmenting the dataset with synthetic images, the model can learn to generalize across different environmental conditions and crop types, improving its predictive performance. Additionally, the research explores the interpretability of the CNN model, providing insights into the learned features and their associations with yield-related factors. Overall, the proposed solution aims to provide more accurate and interpretable predictions of agricultural yields, thereby contributing to improved resource allocation, risk management, and sustainable farming practices.

The following are the research study's principal contributions:

- Employing histogram-equalized images as input to DCGAN-CNN models for effective feature extraction and learning in agricultural yield prediction.
- Utilizing DCGANs for generating synthetic satellite images that closely resemble real-world agricultural landscapes, acting as data augmentation tools.
- Incorporating CNNs to learn spatial and hierarchical representations from artificial and real-world satellite imagery, resulting in more reliable and accurate agricultural yield prediction models.
- Applying Adam optimization algorithm for enhancing the efficiency and performance of DCGAN-CNN models, especially in dealing with the intricate and dynamic nature of satellite imagery datasets.

II. Related Works

The literature review section provides a comprehensive overview of existing research and studies related to agricultural yield forecasting, remote sensing technologies, and deep learning techniques. It highlights key findings, methodologies, and advancements in the field, laying the groundwork for understanding the current state of knowledge and identifying gaps in research. By synthesizing and critically analyzing the existing literature, this section aims to contextualize the proposed approach within the broader academic landscape and elucidate the rationale behind its development.

For the food industry, it is essential to be able to quickly and non-destructively predict how much oil is in a single maize kernel [16]. Unfortunately, gathering a large number of maize kernel oil content reference values is costly and time-consuming, and the model's limited data set also makes it difficult for it to generalize. Here, the oil content of a single maize kernel was predicted using a combination of DCGAN and hyperspectral imaging technology. They simultaneously expanded their spectral and oil content data using DCGAN. Fake data that was strikingly similar to the experimental data was produced after numerous iterations. The performance of the support vector regression (SVR) and PLSR models was compared before and after the augmentation of the data. The outcomes demonstrated that this approach not only enhanced the functionality of two regression models, but also resolved the issue of needing a substantial quantity of training data.

Before starting a farming endeavour, crop selection is a crucial step. Reliable weather data plays a major role in crop output in India by assisting farmers in scheduling their labor to maximize crop productivity [17]. According to a number of researchers, changes in temperature, precipitation, winds, humidity, and carbon dioxide levels all have an immediate impact on crop productivity. Any deviation in the weather creates atmospheric stresses, which increases the risk of financial loss for these farmers. In response to these issues, this manuscript suggests two new methods for predicting weather: the Cycle Consistent GAN with Color Harmony algorithm for choosing crops in the selected in WB, India, and the Recalling Improved Sigmoid RNN with Manta Ray the enhancement for weather prediction. The results show that compared to the conventional methods, the introduced model achieves a higher accuracy. Tests like the Cochran's Q test and the Chi-square test are conducted to demonstrate the statistical analysis of the suggested strategy.

Plant diseases significantly reduce agricultural yields and cause a great deal of damage. Plant disease detection has benefited from the recent development of deep learning techniques, which provide a reliable tool with incredibly accurate results [18]. Images were shot in a variety of weather conditions, at different angles, during the day, and against a variety of backgrounds to simulate real-world scenarios. The number of images in the dataset was increased using two different strategies: cutting-edge generative adversarial networks and conventional augmentation techniques. In order to evaluate the effectiveness of controlled training and application in real-world scenarios for accurately recognizing plant diseases in a complicated context and under varied conditions including the identification of multiple diseases in a single leaf—a number of experiments were carried out. Lastly, novel neural network architecture with two stages was put forth for the classification of plant diseases with an emphasis on the real world. With training, the model's accuracy was 93.67%.

In order to identify plant leaf diseases using leaf images, we developed a brand-new 14-layered DCNN) in this study. Several public datasets were used to create a new dataset. The dataset's individual class sizes were balanced through the application of data augmentation techniques [19]. The following three methods of image augmentation were applied NST, DCGAN, and basic image manipulation. The dataset distinct leaf classes—one without any leaves as well as images of sick and healthy plants. The suggested model underwent 1000 epochs of training in the context of MGPUs. The best hyperparameter values were chosen using a random search using the coarse-to-fine searching technique in order to enhance the suggested DCNN model's training performance. Furthermore, the suggested DCNN model outperformed the current transfer learning techniques in terms of overall performance.

UAV aerial survey technology is widely used in agricultural production; however, signal interference, environmental changes, and other factors can cause missing flight data in aerial survey missions [20]. The paper proposed a complementary model based on VAE-CGAN optimization that employs a new discriminator structure, adds PSA to reduce computational complexity, and uses a combination of conditional CGAN and VAE as a regressor for VAECGAN reduction in order to accurately complement the time-series data. The model performs better than other comparable models in terms of sample generation capacity and prediction results with real aerial survey project datasets, according to comparative experiments. The algorithm is universally applicable on data that has various parameter time series missing rates.

It is difficult to carry out recognizing modeling and diagnosis of leaf diseases by directly using in-situ images from the agricultural Internet of things system because of the complex environments found in real fields. To address this drawback, a method for identifying cucumber leaf diseases in the field was suggested that relies on a deep convolutional neural network and a small sample size [21]. To obtain the lesion images, a single two-stage segmentation method was introduced, which involved removing diseased spots from cucumber leaves. The lesion images were then fed into the activation reconstruction GAN for augmenting the data to produce new training samples after rotation and translation had been applied. Lastly, we suggested using the generated training samples to train a dilated and inception convolutional neural network, which would increase the identification accuracy of cucumber leaf diseases. The experimental results demonstrated that the proposed approach significantly outperformed those of its existing counterparts. The average identification accuracy of 96.11% was achieved.

GANs are prominent in DL, particularly for their capacity to create realistic images and learn complex ST correlations within MTS [22]. Forecasting vegetation, crucial for understanding ecosystem dynamics and land cover changes, presents challenges due to non-stationary ST correlations and external factors like weather. Addressing these challenges, we propose a novel multi-attention GAN model composed of an encoder network to encode input sequences, a generator for long-term temporal pattern extraction, and an improved discriminator for classification and feedback. Extensively tested with real-world data, the model demonstrates superior performance, yielding a Coefficient of Determination (R^2) of 0.95, RMSE of 0.04, MAE of 0.01, and MAPE of 15.35, showcasing its effectiveness and robustness compared to existing methods.

Crop classification using remote sensing data has become increasingly important, with studies indicating that combining SAR and optical images improves classification accuracy. However, a key challenge is the scarcity of training data, particularly for minority crop classes, which impacts classifier performance [23]. Traditional methods struggle to address this issue, as they often fail to effectively generate synthetic data for minority classes. In this study, we investigate the efficacy of conditional tabular generative adversarial networks (CTGAN) in synthesizing data for minority crop classes. Our results demonstrate that CTGAN produces high-quality synthetic data, effectively increasing sample size for minority classes and improving classifier performance in crop classification using SAR-optical data fusion.

The studies that have been discussed all have significant limitations. The use of artificial data raises questions about the way the model captures variations in the real world. In a similar vein, the robustness of the model in real-world meteorological applications may be impacted by the manner in which DCGAN-generated images perform as data augmentation in the tropical cyclone recognition framework. The accurate modeling of weather patterns is a challenge for weather prediction methods utilizing GANs and RNNs, and the specificity of the training data may have an impact on the methods' practicality in real-world scenarios. Despite their innovation, plant infection detection models may not be able to handle a variety of environmental conditions or identify several diseases in a single leaf. Although it outperforms transfer learning techniques, plant leaf disease identification raises concerns about its generalizability beyond particular datasets. Finally, the complementary model for aerial survey data completion may be affected by real-world environmental factors that are not fully accounted for, and careful validation in a variety of agricultural contexts is necessary to ensure its applicability across varying missing rates in time-series data.

III. Problem Statement

From the reviewed literatures that problem addressed that the traditional agricultural yield prediction models have limitations. These include difficulty accurately extracting features from satellite data and inability to generalize across a wide range of environmental conditions. The inhomogeneous pixel intensity distributions in images, which are impacted by variables like shadows and lighting, provide substantial challenges to accurate crop health evaluation [24]. To address these issues, the study uses CNNs for learning hierarchical features and DCGANs for creating synthetic images. Histogram equalization is used as a pre-processing method to improve the adaptability of the model. The main objective is to create a flexible and resilient model that can reliably forecast agricultural yields, supporting sustainable farming methods, wise decision-making, and the security of food supply worldwide.

IV. Proposed Methodology

The methodology section outlines the approach and procedures employed in this study to address the research objectives. It delineates the steps taken to collect, preprocess, and analyse the satellite imagery and agricultural data used for yield forecasting. Furthermore, it details the implementation of the proposed DCGANs and CNNs framework for synthesizing satellite images and predicting agricultural yields, respectively, elucidating the methodology's rigor and reproducibility.

In this study, a comprehensive methodology aimed at enhancing agricultural yield prediction through the integration of CNN and DCGAN with satellite imagery is adopted. The decision to employ this method stems from the need to address existing challenges in agricultural yield prediction, particularly related to irregular pixel intensity distributions in satellite imagery, which can hinder the accurate identification of important features in agricultural landscapes. To overcome this limitation, a crucial pre-processing step involving histogram equalization is introduced, aimed at enhancing the contrast and visibility of significant features. Participants in this study consist of agricultural researchers and practitioners involved in environmental monitoring and precision agriculture, with characteristics including expertise in remote sensing, machine learning, and agricultural science. The data collected comprise a combination of synthetic and real satellite images, with the synthetic images generated through adversarial training using DCGANs for data augmentation purposes. The instruments utilized include satellite sensors for image acquisition, deep learning frameworks for model training, and statistical tools for performance evaluation. Through the integration of CNN and DCGAN, our methodology aims to develop a robust model capable of accurately predicting agricultural yield, thereby advancing environmental monitoring and precision agriculture practices. The suggested methodology's general block diagram is represented in Fig. 1.

A. Data Collection

The dataset is gathered from the dataset web site Kaggle[1]. Satellite imagery labelled with predefined classes is included in the dataset to help with machine learning model training and assessment. With the use of this dataset, image classification algorithms that can automatically classify objects, features, or land cover seen in satellite images will be able to be developed, opening up new applications in the fields of disaster relief, urban planning, agriculture, and environmental monitoring. This dataset is used by researchers to develop computer vision and remote sensing techniques.

B. Histogram Equalization for Data Pre- Processing

A useful pre-processing method for improving the usefulness of satellite imagery in the framework of deep learning models for agricultural yield prediction is histogram equalization. Histogram equalization is essential for enhancing the overall contrast and visibility of important features in the agricultural landscape that the satellite photographs by resolving problems associated with uneven pixel intensity distributions within images. In the field of yield prediction, where precise identification of crop health and patterns is crucial, this technique assists in reducing difficulties related to uneven lighting, shadows, and low contrast areas in the imagery. In addition to improving the satellite images' visual quality, the redistribution of pixel values via histogram equalization gives deep convolutional generative adversarial networks a more insightful input. The enhanced contrast

[1] https://www.kaggle.com/datasets/mahmoudreda55/satellite-image-classification

makes it easier for the model to identify minute differences in the types of soil, vegetation, and other critical components that affect agricultural productivity. Histogram equalization is therefore applied as a pre-processing step to ensure that the input data is more conducive to efficient feature extraction and learning, which helps to optimize DCGAN-CNN based crop-yield prediction models. By extending the intensity range throughout the image, it effectively distributes the levels of intensity and improves the image. When adjacent contrast data reflect the operational values of a picture, this approach increases the image's universal contrast.

Histogram with equalization, a smaller localized intensity differential can yield more contrast. It aims to increase the image's visual appeal and readability. A picture's intensity spreading values can be thought of as arbitrary numbers between 0 and L-1. An additional meaning of "random calculation" is the cumulative distribution function that goes along with it.

Denote the input picture f as an array of numerical pixels with intensities values within the range of 0 to L − 1, where L is the intensity probability value. Additionally, q denotes regularized histogram of the primary image (f). Eq. (1) represents the general formula for q and g.

$$qn = \frac{number\ of\ pixels\ with\ intensity\ n}{total\ number\ of\ pixels}\ \text{n=0, 1 …, L-l} \qquad (1)$$

Eq. (2) represents the histogram equalization of the image

$$h_{i,j} = flor(L-1)\sum_{n=0}^{f_{i,j}} qn \qquad (2)$$

The flor () changed to the closest down integer as a result. This is equivalent to applying the following Eq. (3) to the values of the densities, k, of ‘f ‘:

$$S(k) = flor(L-1)\sum_{n=0}^{k} qn \qquad (3)$$

Considering the densities for f and h as continuous arbitrary values Y, Z over a time span from 0 to L − 1, where Z is a variable, served as the inspiration for this conversion. The intensity formula, represented by Eq. (4), is provided below.

$$Z = S(Y) = (L-1)\int_0^x q(x)dx \qquad (4)$$

where, q(x) is the probability intensity formula for g. S is the product of Y's collective distribution values and product of (L-1). It will be easier to suppose that the variable T is differentiable and invertible. While the function T(X) denotes Y, which is normally distributed.

C. *Deep Convolutional Generative Adversarial Networks for Data Augmentation*

One of the areas of artificial intelligence research that has seen the most development recently is GANs, which are used extensively in a variety of fields including visual forecasting of typhoon clouds, image generation, and image repair. A discriminator and a generator are components of a GAN. The discriminator's goal is to discern among actual and artificially produced pictures as much as possible, while the generator's goal is to render the discriminator incapable of differentiating between true and image generated. An image is the generator's output, and it requires an n-dimensional vector as input.

Any model capable of producing images, like the basic fully connected neural network, can serve as the generator. An image serves as the discriminator's input, and its label serves as its output. The discriminator structure is comparable to the generator structure in a similar way, resembling a network with convolution, etc. Advancement over the original GAN is represented by DCGANs. The following are the improvement's primary contents; rigorous mathematical proof is not included. Convolutional neural networks are used by both the discriminator and the generator. Both discriminators and generators employ batch normalization. The pooling layer is not utilized by either the discriminator or the generator. The generator substitutes fractionally strided convolution for the convolution layer, while the discriminator maintains the CNN architecture. The loss functions of discriminator D and generator G are included in the DCGAN's loss function. The discriminator's parameters are set after the generator has been trained. The generator's parameters are set while the discriminator is being trained.

The generator's goal is to prevent the discriminator from being able to tell the difference between generated and actual TC images as shown in Eq. (5).

$$L_D^{adv} = log(1 - D(G(X)) \qquad (5)$$

The discriminator can be tricked by the generator by minimizing Eq. (6), which prevents the discriminator from differentiating between generated and real images. The L1 loss function is then presented in order to calculate the difference between the generated and actual images as shown in Eq. (7).

$$L_1 = \sum_{a=1}^{q_w}\sum_{b=1}^{q_h}\left||G(X)(a,b) - Y(a,b)|\right|_1 \qquad (6)$$

$$L_G = \lambda_1 L_D^{adv} + \lambda_2 L_1 \qquad (7)$$

where, the empirical weight parameters are λ_1 and λ_2. By reducing Eq. (8), the generator can produce high-quality images.

Differentiating between the generated and actual images is the aim of the discriminator D. The discriminator's adversarial loss function is as follows in order to accomplish this goal:

$$L_D^{adv} = -log(D(Y)) - log(1 - D(G(X)) \qquad (8)$$

In Eq. (8), an infinite situation will arise if the generated image is incorrectly judged as the real image, or if the real image is incorrectly judged as the generated image. This implies that the discriminator needs to be optimized. A progressive decrease in Eq. (8)'s value indicates that the discriminator is becoming increasingly well-trained.

In the field of agricultural yield prediction, Deep Convolutional Generative Adversarial Networks are effective instruments for feature extraction from satellite imagery. An improvement on conventional GANs, DCGANs are made expressly to extract and assimilate hierarchical features from large, complex datasets. With regard to satellite imagery, DCGANs are particularly good at identifying complex spatial and spectral features that may be difficult for traditional methods to extract. In this context, subtle patterns and nuanced information are critical for accurate yield predictions.

DCGANs are made up of a discriminator and a generator that collaborate through adversarial training. The discriminator assesses the authenticity of these generated images in comparison to real ones, while the generator attempts to replicate the true distribution of the input data by synthesizing realistic images from random noise. This competitive process forces the generator to continuously enhance its capacity to generate images that are identical to real satellite data, efficiently recognizing and encoding complex patterns present in the imagery.

DCGANs are especially useful for extracting features like crop health indicators, vegetation distribution, and soil properties when it comes to agricultural yield prediction. The model can automatically recognize and abstract complex features at different scales, capturing both local and global patterns within the satellite imagery, thanks to the hierarchical structure of the convolutional layers in DCGANs. Subsequently, these acquired characteristics can function as comprehensive depictions for subsequent assignments, contributing to precise crop yield forecasting.

The spatial relationships and contextual information found in satellite images are naturally utilized by DCGANs. Convolutional layers give the network the ability to detect spatial hierarchies, which is essential for figuring out how crops are arranged, pinpointing specific areas, and encapsulating the diversity of agricultural landscapes. As a result, the generated features offer a thorough depiction of the fundamental features and structure of the agricultural terrain, enabling more accurate yield predictions. The application of DCGANs to feature extraction from satellite imagery presents a refined method for identifying and encoding complex spatial relationships and patterns in the data. DCGANs are especially well-suited for the intricate and nuanced task of agricultural yield prediction because of their hierarchical feature learning capabilities, which provide a solid basis for further model training and optimization. The DCGAN's architectural diagram is illustrated in the Fig. 2.

D. Convolutional Neural Network for Agricultural Yield Prediction

CNNs play a pivotal role in leveraging satellite imagery to make accurate predictions. CNNs excel in learning hierarchical and spatial representations from images, making them particularly effective for capturing intricate patterns and features present in agricultural landscapes. Trained on a dataset comprised of real and synthetic satellite images, where the latter is generated using a DCGAN to augment the available data, the CNN learns to automatically extract relevant features associated with crop health, growth, and other factors influencing yield. The convolutional layers of the network act as localized feature detectors, identifying distinctive spatial patterns in the images, while subsequent layers integrate these features for high-level representation and prediction. Through this process, the CNN becomes adept at discerning subtle variations in satellite imagery, contributing to a robust and accurate model for agricultural yield prediction, which is crucial for informed decision-making in precision agriculture and resource optimization.

The source data is passed through a series of "filters" by convolutional layers. Every filter is made to identify a particular pattern or feature, like corners, edges, or, in the case of deeper layers, more intricate shapes. These filters result in a map that shows the locations of the characteristics as they move across the image. The output of the convolutional layer is a feature map, which is a representation of the source data with the filters applied. Convolutional layers can be stacked to create more complex models with a higher capacity to extract finer details from images. Convolutional layers, put simply, are in charge of extracting features from the input images. These characteristics could be corners, edges, textures, or intricate patterns. Eq. (9) represents the input pixel, filter and the value at the position

$$A(p,q) = \sum x \sum y\, B(p+x, q+y) * E(x,y) + b \qquad (9)$$

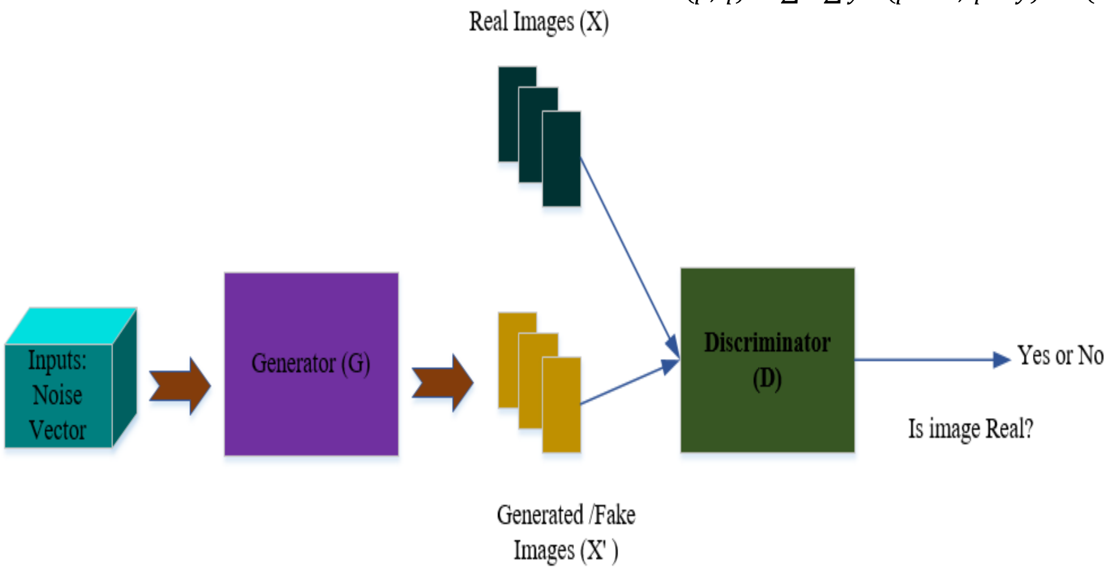

Fig. 2. DCGAN's architectural diagram.

where, A (p, q) is the value in the future map at position (x, y).

B $(p+x, q+y)$is the input image pixel at position $(p=x, q=y)$

E (x, y) is the filter/kernel at position (x, y).

b is the bias term

Pooling layers are used to speed up analysis and decrease the spatial extent of the user's input. They are the next in the processing hierarchy after convolutional layers. In the context of images, "spatial dimensions" refers to the height and width of the image. The fundamental units of an image are called pixels, which resemble rows and columns of tiny squares. By reducing the spatial dimensions, pooling layers help lower the number of factors or weights in the system. This expedites the model's training process and helps avoid overfitting. Because max pooling reduces the size of the feature map and makes the model invariant to small transitions, it aids in lowering computational complexity.

The network wouldn't be able to identify features regardless of slight rotations or shifts without max pooling. This could potentially reduce accuracy by weakening the model's resistance to changes in object positioning within the image.

For example, if the pooling window is 2 by 2, the highest-valued pixel in that 2 by 2 region will be selected. Max pooling effectively captures the most notable feature or characteristic within the pooling window. Using average pooling, the sum of all values within the pooling window is found. It provides a picture of typical, rounded features. Eq. (10) denotes the maximum pooling function. The CNN architectural diagram is given in Fig. 3.

$$F(p,q) = \max(F(2r,2s), F(2r,2r+1), F(2r+1,2s), F(2r+1,2s+1)) \quad (10)$$

E. Adam Optimization for Enhancing DCGAN-CNN Model

Adam is ideally suited for the intricate and dynamic nature of deep neural network training since it combines adaptive learning rates with momentum. The algorithm's adaptive features facilitate the efficient adjustment of learning rates for individual model parameters by utilizing the historical gradients. This leads to a stable and robust convergence. This flexibility comes in handy when working with datasets of satellite imagery, where intricate spatial patterns and variable data distributions call for an optimization algorithm that can navigate a wide range of complex and subtle terrain. Adam's scalability to manage massive amounts of high-dimensional satellite imagery data is further enhanced by its efficient memory usage, which is attained by preserving moving averages of gradients and squared gradients. Moreover, compared to conventional optimization techniques, Adam's simple implementation and reduced hyperparameter requirements make it a practical and effective option for remote sensing and agricultural analytics professionals. By using Adam, researchers and practitioners can improve DCGAN-CNN performance and training efficiency, which will lead to more accurate and dependable predictions in satellite-based applications.

It combines the advantages of momentum and Root Mean Square Propagation, two other optimization techniques. Adam works well in a range of machine learning scenarios by adjusting the learning rates of individual model parameters based on the historical gradients.

Two moving averages, one for the gradients (first moment) and another for the squared gradients (second moment), computed exponentially over time, are essential components of Adam. Setting hyper parameters during initialization includes determining the learning rate (α), the decay rate in the first moment estimate (β_1), and the decay rate in the second moment estimate (β_2). The algorithm uses exponential decay to update the first and second moment estimates at each iteration and computes the gradient of the loss with respect to model parameters. Adam presents terms for bias correction in order to address biases towards zero.

Using exponential decay, update the first moment estimate (mean of gradients) and the second moment estimate (mean of squared gradients) is expressed in Eq. (11) and Eq. (12).

$$n_t = \beta_1 . n_{t-1} + (1-\beta_1) . g_t \quad (11)$$

$$o_t = \beta_2 . o_{t-1} + (1-\beta_2) . (g_t)^2 \quad (12)$$

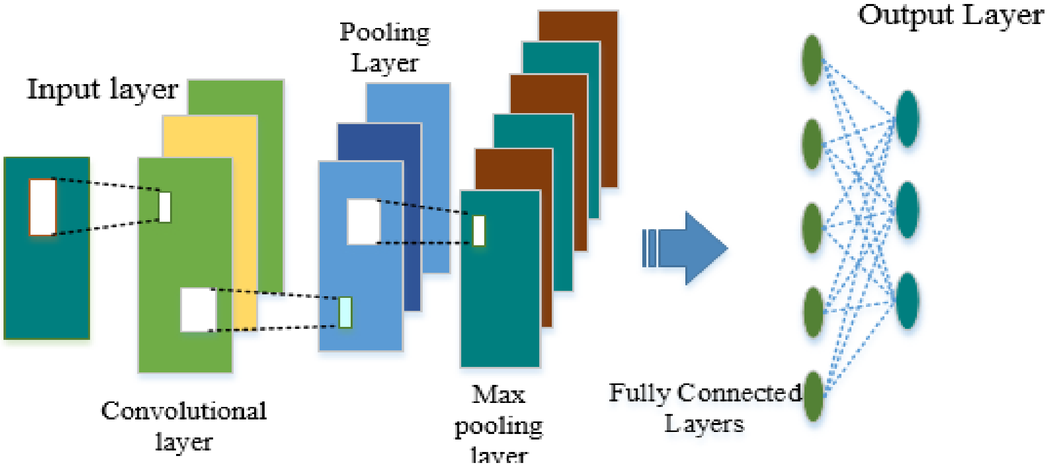

Fig. 3. CNN architectural diagram.

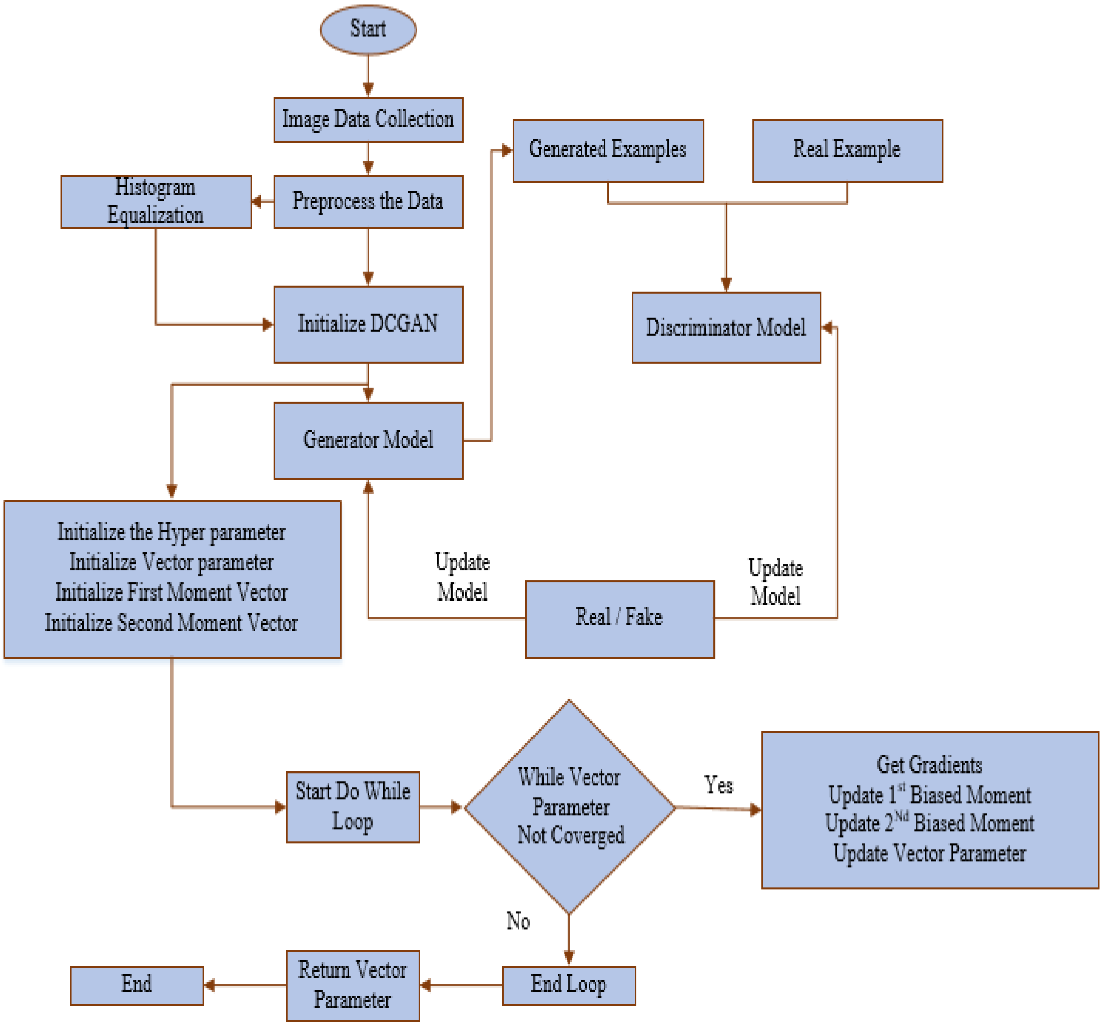

Fig. 4. Flowchart of the proposed AO optimized DCGAN method.

where, the gradient is denoted by g_t, and the first and second moment estimates at iteration t are represented by n_t and o_t, respectively. Particularly in the early iterations, there is a bias towards zero in the estimates of n_t and o_t.

Adam presents terms for bias correction in order to address this bias. Eq. (13), Eq. (14) and Eq. (15) represents,

$$\widehat{n_t} = \frac{n_t}{1-\beta_1^t} \tag{13}$$

$$\widehat{o_t} = \frac{o_t}{1-\beta_2^t} \tag{14}$$

$$\theta_{t+1} = \theta_t - \alpha.\frac{\hat{n}_t}{\sqrt{\hat{v}_t + \epsilon}} \tag{15}$$

The model parameter at iteration t is represented by θ_t, the learning rate is represented by α, and division by zero is maintained by the small constant ϵ. The final step updates the model parameters using the bias-corrected estimates. Adam is a powerful optimizer because of its adaptability, real-world efficacy, and combination of momentum and RMSprop. The best results require experimentation and fine-tuning because task-specific characteristics and hyper parameter selection determine its performance. Adam is a good neural network training optimizer due to its momentum incorporation and adaptive features. Fig. 4 shows the flowchart of the proposed AO Optimized DCGAN Method.

V. Results and Discussion

The results section presents the outcomes of the empirical analysis conducted in this study, elucidating the effectiveness and performance of the proposed methodology in agricultural yield forecasting. It provides a detailed overview of the model's predictive accuracy, robustness, and generalization capabilities across different environmental conditions and crop types. Additionally, the results section offers insights into the interpretability of the model, highlighting key features and factors influencing yield predictions, thereby contributing to a deeper understanding of the underlying dynamics of agricultural production.

In this section, the research present the results obtained from our novel approach integrating DCGANs with satellite imagery for the purpose of optimizing agricultural yield prediction. The utilization of DCGANs allowed us to generate synthetic satellite images, enabling the augmentation of our training dataset and enhance the model's ability to generalize across diverse agricultural landscapes. Through extensive experimentation, we evaluate the performance of our proposed methodology in comparison to traditional yield prediction models. Our results shed light on the efficacy of DCGANs in extracting meaningful features from satellite imagery, providing valuable insights into the potential advancements and improvements that can be achieved in the realm of precision agriculture. When combined, the metrics that the research evaluates provide a strong basis for assessing and maximizing the efficiency of DCGANs in satellite imagery-based agricultural yield prediction. The performance of the model across these crucial metrics will be thoroughly examined and its implications will be discussed in the results section that follows, providing insight into the model's potential to improve agricultural prediction processes.

A. *Performance Metrics*

Metrics that quantify the accuracy, precision, and overall efficacy of the model are essential when assessing the way a DCGAN predicts agricultural yields from satellite imagery. The objectives of the agricultural yield prediction task should be taken into consideration when designing these metrics. The following metrics are frequently employed when assessing DCGANs and contrasting them with conventional techniques

1) Mean squared error: The average squared difference between the model's predicted agricultural yield values and the dataset's actual observed yields is measured by a performance metric called mean squared error, or MSE. A lower MSE value reflects a higher degree of accuracy in the DCGAN's agricultural productivity predictions by indicating that it is better at minimizing the overall difference between predicted and true yield values. The following Eq. (16) is the formula for mean squared error:

$$MSE = \frac{1}{n}\sum_{p=1}^{n}(y_{p-}\hat{y}_p)^2 \tag{16}$$

where,

The total number of instances in the dataset is represented by n.

For p th instance, y_p represents the actual agricultural yield that was observed.

For p th instance, $\hat{y}_p$ denotes the expected yield calculated by the DCGAN.

The mean squared error (MSE) is computed by averaging the squared deviations between the observed and anticipated values for every example in the dataset. This metric provides a quantitative assessment of the model's accuracy in predicting agricultural yields by penalizing larger errors more severely.

2) Accuracy: Assessing the accuracy by contrasting the predicted class labels your model generates with the ground truth (actual) labels for your test dataset. After processing all of the test photos to determine accuracy, increase the "Number of Correct Predictions." and divide this count by the "Total Number of Predictions" if the projected label for an image in the test dataset matches the actual label. Accuracy is commonly determined by applying Eq. (17).

$$Accuracy = \frac{RN+RP}{RP+AP+RN+AN} \tag{17}$$

The accuracy metric assesses the percentage of correctly classified instances, offering valuable information about the DCGAN's capacity to identify and replicate significant patterns associated with crop yield throughout the complete dataset. A high accuracy shows that the model is able to learn and generalize from the satellite imagery in an efficient manner, resulting in dependable predictions for the evaluation of agricultural yield.

3) Precision: Precision is a commonly measured quantity, primarily in statistics and machine learning. It assesses a model's ability to make positive predictions about the future. The ratio of accurate forecasts to all reliable forecasts is known as precision. It is commonly combined with other classification model metrics like accuracy, F1-score, and recall. The formula for precision in Eq. (18) is as follows:

$$Precision = \frac{True\ Positives}{(True\ Positives+False\ Positives)} \tag{18}$$

The number of correctly predicted positive outcomes is known as True Positives. The number of negative events that the model misinterpreted as positive is known as False Positives (FP). The precision level is a number between 0 and 1, where 1 represents perfect precision (all correct positive predictions) and 0 represents no correct positive predictions. To use this equation, a dataset containing the ground truth labels and the model's predictions is required. Next, ascertain precision by counting the true positives and negatives using the previously described method.

A high precision value indicates that the DCGAN minimizes false positives by being effective in identifying regions of interest linked to high crop yield. Precision is particularly important in agriculture because it highlights the model's capacity to offer reliable and accurate insights into regions where ideal yields can be anticipated, assisting farmers and other stakeholders in making well-informed decisions.

4) Recall (sensitivity): Recall is also known as sensitivity and true positive rate. The ability of the model to correctly identify each relevant instance of a given class that is present in the dataset is referred to as recall. It determines the percentage of true positive predictions, or correctly detected instances of a class, out of all real positive occurrences for that class. Recall can be defined as mathematically in Eq. (19)

$$Recall(sensitivity) = \frac{True\ Positives}{True\ Positives+False\ Negatives} \tag{19}$$

A high recall value means that the DCGAN minimizes false negatives by effectively capturing a sizable portion of the regions linked to optimal agricultural yields. To ensure that the model can consistently identify and highlight areas of interest in agricultural applications and help farmers and decision-makers optimize their resource allocation and management strategies, a high recall is necessary.

5) Specificity: The proportion of accurately anticipated negative observations to all actual negative observations is defined as specificity. Eq. (20) is used to compute it:

$$Specificity = \frac{True\ Negatives}{True\ Negatives + False\ Positives} \tag{20}$$

Specificity is frequently shown against sensitivity (True Positive Rate) at different categorization levels within the framework of the ROC curve. A high specificity number means that the occurrences of the negative class are accurately identified by the model, and they are not being incorrectly classified as positive.

6) F1-Score: The F1 score is particularly useful in datasets that are unbalanced meaning that one class significantly outnumbers the other. The following Eq. (21) is used to determine the F1 score:

$$F1\ Score = 2 * \frac{(Precision * Recall)}{(Precision + Recall)} \tag{21}$$

A model that successfully strikes a balance between the accuracy of positive predictions and the capacity to record all pertinent cases is indicated by a higher F1 score, which provides a thorough indicator of overall predictive accuracy.

7) AUC: The ROC curve, which plots the True Positive Rate (sensitivity) versus the False Positive Rate (one-specificity), provides a graphic representation of a model's performance across different classification thresholds. The range of the AUC is 0 to 1, where:

The model performs no better than chance, according to an AUC of 0.5.

AUC > 0.5 denotes performance that is superior than chance, and higher values signify improved discriminative capacity.

The capacity of a model to distinguish between positive and negative occurrences, such as a DCGAN in agricultural yield prediction, an improved model's ability to distinguish pertinent agricultural features is indicated by an AUC value that is closer to 1, which makes it a useful metric for assessing the model's overall discriminatory power.

TABLE I. THE SUGGESTED METHOD'S PERFORMANCE METRICS ARE COMPARED TO THOSE OF EXISTING METHODS

Method	Accuracy (%)	Precision (%)	Recall (%)	F1 Score
YOLO v3 [25]	93.96	80.64	85.9	89
Deep CNN [21]	96.11	90.67	93.90	89.56
Two Stage Neural network [18]	95.38	90.18	85.52	86
Proposed AO-DCGAN+CNN	98.6	98.2	97	96

Compared to YOLO v3, Deep CNN, and Two Stage Neural Network, the proposed AO-DCGAN+CNN model achieves the highest accuracy of 98.6%, outperforming the other methods is given in Table I. Compared to state-of-the-art methods, it demonstrates superior precision (98.2%), recall (97%), and F1 Score (96%), demonstrating its efficacy in precise object detection and classification.

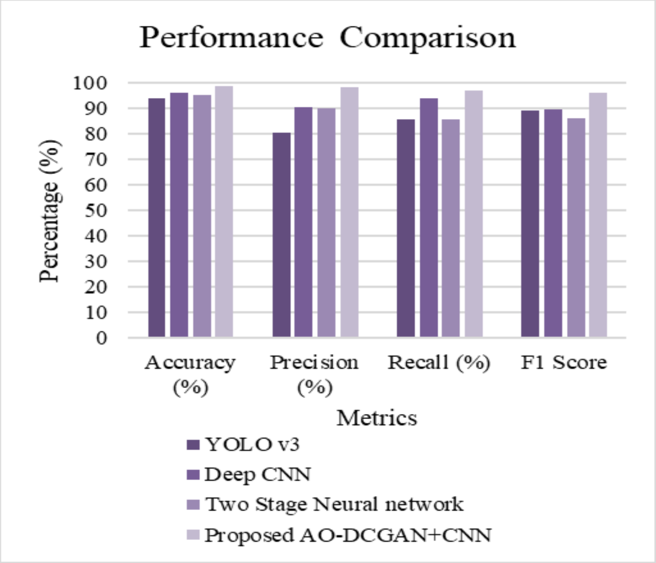

Fig. 5. Visual representation of the performance measures of the suggested DCGAN+CNN's using traditional methods.

Fig. 5 shows the performance metrics of the proposed DCGAN+CNN model in comparison to conventional techniques. The graphical representation highlights the proposed model's superior accuracy; precision, recall, and F1 score over traditional methods, demonstrating how effective it is at advancing agricultural yield prediction.

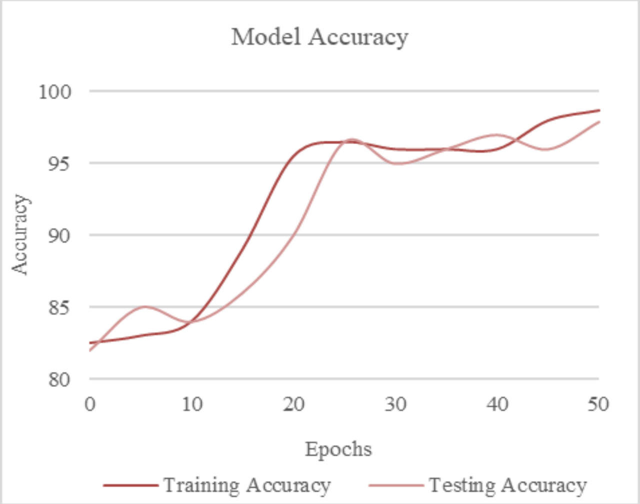

Fig. 6. The suggested DCGAN+CNN method's graphical representation for both training and testing accuracy.

The suggested DCGAN+CNN method is graphically represented in Fig. 6, which shows the accuracy of both training and testing. In addition to confirming the model's effectiveness in maintaining high accuracy during testing, the visual highlights the model's performance dynamics throughout the training process, offering insights into its learning behavior.

Table II provides an extensive analysis of the performance metrics of the Proposed DCGAN+CNN, demonstrating its superior MSE of 8.20% in comparison to conventional techniques.

TABLE II. EVALUATION OF PROPOSED DCGAN+CNN PERFORMANCE METRICS USING TRADITIONAL METHODS

Methods	MSE (%)
Random Forests	17.98
KNN	25.64
Proposed DCGAN+CNN	8.20

The fitness graph for the suggested Adam optimizer is shown graphically in Fig. 9. The figure illustrates the way optimization algorithm works, highlighting how it can adjust and improve the DCGAN+CNN model's training efficiency, which leads to better overall performance in agricultural yield prediction.

B. Discussion

In order to improve agricultural yield prediction, a novel method that combines DCGANs with satellite imagery is presented in this study. By creating synthetic satellite images, DCGANs improve the training dataset and the model's ability to generalize across various agricultural landscapes. A thorough assessment of the model's effectiveness is provided by the performance metrics, which include Mean Squared Error, Accuracy, Precision, Recall, Specificity, F1 Score, and AUC. The findings show that the suggested AO-DCGAN+CNN model outperforms the current techniques, attaining high F1 Score (96%), recall (97%), accuracy (98.6%), and precision (98.2%). To further demonstrate the efficacy and learning behavior of the model, visual representations of performance metrics, training accuracy, testing accuracy, and ROC curve are provided. According to the research, there is great potential for improving precision agriculture through the integration of DCGANs with satellite imagery. This integration can provide valuable insights into managing strategies and allocating resources optimally for better agricultural yield prediction.

The performance metrics of various methods, including YOLO v3 [25], Deep CNN [21], Two Stage Neural Network [18], and the proposed AO-DCGAN+CNN, for agricultural yield forecasting is discussed. The proposed approach outperforms existing methods, achieving an accuracy of 98.6%, precision of 98.2%, recall of 97%, and F1 score of 96%. This indicates the superior predictive accuracy and robustness of the AO-DCGAN+CNN model compared to YOLO v3, Deep CNN, and Two Stage Neural Network, highlighting its potential to enhance agricultural yield forecasting and contribute to sustainable farming practices.

VI. Conclusion and Future Work

In conclusion, the integration of DCGANs, CNNs, and satellite imagery proves to be a promising approach for optimizing agricultural yield prediction. When DCGANs are used to generate synthetic images for data augmentation, the model's capacity to generalize to a variety of environmental conditions is improved, leading to predicted outcomes that are more accurate. Using CNNs makes it easier to extract features that are useful for crop health assessment, as they can capture complex patterns and spatial representations. The model is even more flexible in different lighting conditions appreciations to the pre-processing method of histogram equalization. The framework that has been suggested exhibits promise in tackling issues related to unequal distributions of pixel intensity in satellite imagery. In the future, the scope will include investigating more sophisticated methods to improve model performance and generalization across various geographic locations, such as transfer learning and attention mechanisms. Furthermore, the model's predictive abilities could be improved by adding weather parameters and real-time satellite data, which would make it a useful tool for precision agriculture in the face of changing climate conditions. It is possible to improve agricultural technology, guarantee food security, and promote sustainable farming practices by carrying out more research in this area. Despite the promising results, several limitations and avenues for future research exist in enhancing agricultural yield forecasting with DCGANs and satellite data. Firstly, the effectiveness of the proposed approach may be influenced by the availability and quality of satellite imagery, as well as the heterogeneity of agricultural landscapes. Future work could focus on addressing these challenges through the development of more sophisticated DCGAN architectures capable of generating higher-fidelity synthetic images and incorporating additional environmental variables for improved accuracy. Furthermore, research could explore the integration of real-time weather data and other relevant agricultural indicators to enhance the predictive capabilities of the model. Additionally, there is a need for comprehensive validation and verification of the proposed approach across diverse geographical regions and crop types to ensure its generalizability and robustness. Finally, investigating the scalability and computational efficiency of the model for large-scale applications would be beneficial for practical deployment in agricultural decision-making and policy formulation.

Analyzing Multiple Data Sources for Suicide Risk Detection: A Deep Learning Hybrid Approach

Saraf Anika, Swarup Dewanjee, Sidratul Muntaha
Computer Science & Engineering, East Delta University, Chattogram-4209, Bangladesh

***Abstract*—In the current digital landscape, social media's extensive user-generated content presents a unique opportunity for identifying emotional distress signals. With suicide rates on the rise, this study takes aid of Natural Language Processing (NLP) and Sentiment Analysis to detect suicide risk. Centering primarily around deep learning (DL) architectures, including Convolutional Neural Network (CNN), Bidirectional Gated Recurrent Unit (Bi-GRU) and their combined hybrid BiGRU-CNN model, the research incorporates machine learning (ML) for comparative analysis through multisource datasets from Reddit and Twitter. The methodology commenced with data pre-processing, followed by exploring word embedding techniques. This research included an analysis of both Word2Vec variants as well as pretrained GloVe embeddings, where Skip-Gram paired with Adam optimizer showed superior results. For thorough evaluation, Receiver Operating Characteristic (ROC) curves, Confusion Matrix and Accuracy-Loss graphs were utilized. Furthermore, generalizability of employed models was testified and evaluated by in-depth inspections. The process was accomplished by activating manual input test, cross dataset test and k-fold cross validation procedures. In the course of scrutinizing, the proposed BiGRU-CNN model outperformed the traditional DL and ML models with consistent and reliable performance. Correspondingly, the proposed model achieved accuracies of 93.07% and 92.47% on the respective datasets which advocate its potential as a tool for the early detection of suicidal thought.**

Keywords—BiGRU-CNN hybrid; multisource dataset; word embeddings; NLP; sentiment analysis; cross-dataset testing

I. Introduction

Suicide is a deeply sensitive and significant issue that demands empathy and understanding. The World Health Organization (WHO) carried out a research investigation in 2021 that declares suicide as a prominent and relentless global cause of death. According to [1] and [2], annually 0.7 million people die by suicide marking it as fourth leading cause of death. Reportedly, majority of the victims fall under the age group of 15 to 29 years. Over the past 15 years, the world witnessed a 24% increase in the overall suicide rate as per The National Institute of Mental Health [3]. In the pandemic year of 2020 suicides increased by 10% from previous year in India and reached a record high of 1, 53, 052 [4].

Suicidal thoughts can arise from various factors like mental health issues, societal pressures, isolation and hopelessness. Social media platforms provide a practical angle for analyzing mental health indicators as individuals tend to often express their emotions and struggles there. Traditional methods for assessing suicide risk are often limited by their time-consuming nature and inability to detect immediate risks. This has led to a paradigm shift towards employing Artificial Intelligence (AI) for text analysis as AI promises enhanced accuracy and efficiency. Human emotions from textual data now can be deciphered by automated system with the help of evolving areas of NLP [5] and Sentiment Analysis [6].

This research sought to detect early signs of suicidal thoughts by developing an automated system. The study proceeded with collecting data from social media platform like Reddit and Twitter. Consequently, the effectiveness of DL architectures was evaluated, particularly CNN, Bi-GRU along with their combined hybrid BiGRU-CNN model. These models were chosen due to their ability of extracting local features and capturing sequential, contextual information from text. ML models including Linear Support Vector Classifier, Logistic Regression, Decision Tree and AdaBoost were selected. Additionally, the study conducted a performance comparison of the proposed hybrid model against these traditional ML and DL algorithms to establish a benchmark. Metrics such as accuracy, precision, recall and F1-scores were evaluated to assess the model's performance.

By addressing the research objective, this study aims to create an automated system that scans social media content to identify early signs of suicidal thoughts and provide a tool for suicide risk detection. This system ought to underscore the significant implications for helping people struggling with suicidal thoughts. The proposed model is anticipated to aid in timely interventions to support individuals who are exhibiting signs of distress on social media platforms.

The core contribution of this work was in implementing the proposed hybrid BiGRU-CNN model, employing both ML and DL models, experimenting upon multiple datasets, conducting trials on various word-embedding techniques and performing cross-dataset test by taking advantage of multi-source data. Moreover, this work assessed and verified the potential of the generalization ability of the models through cross-validation and manual dataset creation. The study demonstrated the superiority of the proposed model through these meticulous process for suicide detection across both datasets. These processes ensure a significant improvement over existing research that often overlook or insufficiently emphasize these vital facets.

The structure of our research paper is methodically organized into following key sections: Section II reviews the relevant existing work. Section III thoroughly describes the employed methodology and explains carried out experiments. Section IV presents the outcomes of the various architectures tested as well includes an in-depth analysis. Section V provides an interpretation of the discussion. The paper concludes with Section VI, summarizing the findings. Conclusively, Section VII suggests future research.

II. Related Work

We explored the extensive research on depression and suicide risk detection. To capture insights within this domain, we studied researches working on a wide range of methods and data sources.

The research outlined in study [7] explored potential suicidal thoughts in 49,178 tweets using text preprocessing techniques and feature extraction methods. Various DL techniques were trained including LSTM, Bi-LSTM, GRU, Bi-GRU, and a hybrid CNN-LSTM to check the proficiency. Upon evaluation, the Bi-LSTM model stands out with a high accuracy of 93.6% in handling the nature of tweet data.

In study [8], the authors proposed a hybrid model combining CNN with Bi-LSTM to detect depression from Twitter data. The proposed model outperformed traditional RNN and CNN models, achieving a remarkable accuracy of 94.28%.

Another study utilized Reddit data to test the LSTM-CNN hybrid model through the use of Word2Vec embedding techniques. The outshining results confirmed the model’s usefulness in text classification [9].

The authors of study [10] predicted text data-based depression with proposed RNN-LSTM techniques, using one-hot approach. Considered data was collected from Kaggle and processed via stemming and lemmatization. The proposed technique proved its ability with a commendable accuracy, excelling other methods like Naive Bayes, Support Vector Machine (SVM), CNN, and Decision Trees.

The investigator’s work in study [11] employed various text representation techniques like TF-IDF and Word2Vec, along with a combination of DL (CNN-BiLSTM) and ML (XGBoost) algorithms for text classification.

In contrast to other research, the study [12] applied text mining techniques and numerous algorithms to categorize Cantonese YouTube comments for suicide risk. The paper handled data imbalance using re-sampling and focal loss methods, resulting in g-mean scores of 84.3% and 84.5% for the LSTM model. The best performing model demonstrates the potential for effective automatic suicide risk detection in social media content.

While comparing with SVM, CNN, LSTM and LSTM-CNN combined model, the findings of [13] showcased the efficacy of LSTM-attention-CNN model with 90.3% accuracy. The researchers extracted the Reddit dataset with the assistance of Reddit API to train their employed models.

These previous researches have made significant contributions to the field of suicide detection. However, several limitations exist including reliance on single dataset that may limit the generalizability of their findings and limited exploration of word embedding techniques. Most studies have solely focused on either ML or DL model for their analysis, thereby overlooking the potential benefits of integrating both approaches.

Building upon the strengths of previous research in suicide detection, this study aimed to address key limitations through a comprehensive approach. To get a broader understanding of how people express themselves in different contexts, this research used multiple datasets from various platforms, like Reddit and Twitter. Instead of relying solely on training and testing within the same dataset, a novel cross-dataset testing methodology was implemented. Here, the model was trained on one dataset and then tested on others. This innovative testing process helps in understanding the model’s adaptability in real-world applications. Additionally, the study went beyond the commonly used Word2Vec technique and also incorporated pre-trained GloVe embeddings to allow the model to capture meaning from the text.

By addressing these limitations and employing these approaches, our research intends to contribute meaningfully to the advancement of suicide detection and mental stability observation.

III. Experimental Methodology

A. Origin of Data

This study operated on multi datasets for the purpose of ensuring diverse and comprehensive collection of textual content related to mental health and suicidal thought. The Reddit dataset was obtained from the “Suicide Watch” section on Kaggle.[1] It consists of a balanced collection of 232,074 posts which was equally divided with 116,037 posts each in the ‘suicide’ and ‘non-suicide’ categories. Additionally, the Twitter dataset was collected from a GitHub repository.[2]It comprises 9,119 tweets and categorized as 5,121 non-suicidal (0) and 3,998 suicidal (1) tweets. The deliberate selection of data from multiple platforms was critical for the models in understanding the expressions of suicidal thought. Table I carries a general overview about the utilized datasets by presenting few sample texts along with their assigned class labels.

TABLE I. Sample Text of Suicidal and Non-suicidal Context

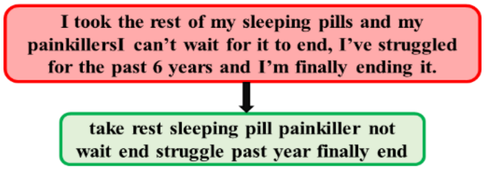
Dataset	Text	Class
Reddit	It ends tonight. I can’t do it anymore. I quit.	Suicide
	Its almost 2 am Why am I tired?? It's so early damn	Non-suicide
Twitter	i am looking for someone to talk to all i want to do is die	1
	attempting a poetry essay listening to jessie rose and feeling fat	0

B. Data Preprocessing

Real-world data often comes in a messy and unorganized form with mistakes and irrelevant details. This complexity and inconsistency can negatively impact in model’s ability and lead to inaccurate predictions. Pre-processing is a fundamental step that converts those raw data into structured format and positively influence the efficacy of the models.

[1] https://www.kaggle.com/datasets/nikhileswarkomati/suicide-watch
[2] https://github.com/laxmimerit/twitter-suicidal-intention-dataset

In our study, the process initiated by removing accented characters and expanding contractions to standardize text expressions. Successively stopwords, symbols URLs, digits, and special characters was discarded to eliminate noise from data. Further refinement included lemmatization, correction of spelling mistakes, and word lengthening. Irreverent words and posts with no content were excluded to eliminate potential noise and bias in the datasets. With the help of a sample text, the process is depicted in Fig. 1. Here red box contains the raw text and cleaned text is presented in the green box.



I took the rest of my sleeping pills and my painkillersI can't wait for it to end, I've struggled for the past 6 years and I'm finally ending it.
take rest sleeping pill painkiller not wait end struggle past year finally end

Fig. 1. Sample of preprocessing technique.

Reddit dataset consisted an unnamed column that was irrelevant to this task and was dropped in the cleaning step. After performing data cleaning, Reddit dataset exhibited a class imbalance with 'suicide' posts at 38.9% and 'non-suicide' at 61.1%. The imbalance arose due to original dataset had several 'suicide' labelled rows without any corresponding texts. Consequently, under-sampling was introduced to tackle the potential bias toward the majority class and improve model's performance. Collectively, these preparations were pursued to enhance the model's capability for accurate understanding and detection of the texts.

C. Word Embeddings

Word embedding [14] techniques provide a means of converting textual data into numerical form so that semantic meanings and relationships between words can be captured. This paper exploited both approach of Word2Vec, namely Skip-Gram and Continuous Bag of Words (CBOW) methods to turn words into useful vectors and trained on cleaned-up text from Twitter and Reddit. Moreover, GloVe (global vectors for word representation) embeddings was explored as well, specifically the GloVe 6B dataset collected from online.[3] The pre-trained models such as GloVe present an extensive vocabulary with vectors trained on a vast corpus, therefore, offer a profound source of semantic data.

D. System Overview with Classifiers

The core of our methodology was characterized by the deployment of both ML and DL models along with several word embedding techniques. The architecture in Fig. 2 summarized this entire process, highlighting the systematic and data-driven approach of our research where BiGRU-CNN was denoted as "Hybrid" and AdaBoost was as "Ensemble" methods.

After collecting and pre-processing the data, cleaned data was split into training, validation and testing sets. Following that, training and validation datasets underwent word embedding process through tokenization, effectively transforming the textual data into vector representations. Subsequently, these vectorized data were utilized to train and validate the models. Based on the validation and testing accuracies, manual hyper-parameter tuning was performed. Moreover, the models went under Cross-validation to understand their performance against different subsets of the data. To analyze the effectiveness of the models against unseen data, manual text input was provided for predicting. On top of that, cross-data testing strategy was implemented to ensure versatility, where models were trained on one dataset and tested against the other. Upon performance comparison, the best model was then chosen as proposed model.

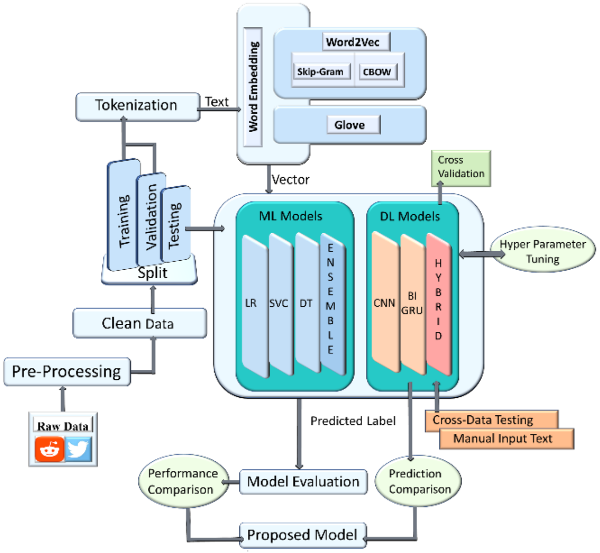


Fig. 2. Architecture of the proposed system.

1) BiGRU-CNN:

The proposed model architecture depicted in Fig. 3 combined the features of Bi-GRU and CNN with a view to improve the capability of classifying suicidal text.

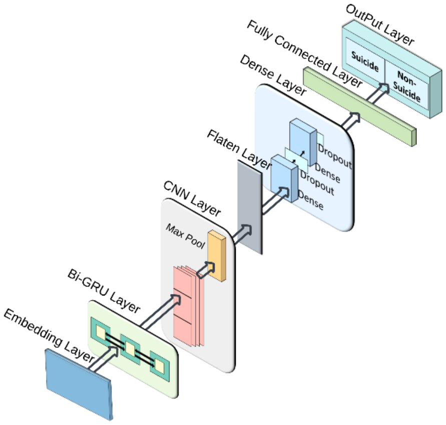

Fig. 3. Proposed model architecture.

While implementing the hybrid model, initially an embedding layer was established that converted text into dense vectors through word embedding. Building on this, a Bi-GRU layer intricately processed these embeddings, capturing the textual context from both forward and backward directions. Thus, it formed a more elaborate representation of the input sequence. The subsequent Conv1D layer applied convolutional

[3] https://nlp.stanford.edu/projects/glove/

operations with multiple filters which proficiently identified and extracted key local features and patterns that were indicative of suicidal thought. Thereafter, dimensionality reduction was achieved through a MaxPooling layer, followed by flattening for dense layer compatibility. Ultimately, dense layers with dropout regularization guided to the output layer, where a sigmoid activation function was employed to compute the probability of suicidal thought.

The layers and parameters along with their corresponding values are tabularized in Table II.

TABLE II. PARAMETERS USED IN PROPOSED MODEL

Layers	Parameters	Values
Embedding	Embedding Dimension	100
Bi-GRU	Units	64
	Dropout Rate	0.25
Conv1D	Filters	128
	Kernel Size	3
	Activation Function	ReLU
MaxPooling1D	Pool Size	2
Dense	Units	128, 64
	Activation Function	ReLU
	Regularization	L2 (0.01)
Dropout	Dropout Rate	0.5
Output	Activation Function	Sigmoid
	Optimizer	Adam
	Loss Function	Binary Cross-entropy
	Batch Size	Twitter Dataset (32)
		Reddit Dataset (128)
	Epoch	20

In our study, we Initialized embedding layer with weights and embedding dimension from the pre-trained Word2Vec and GloVe models. It acts as:

$$Embedded(i) = EmbeddingMatrix[i] \tag{1}$$

Here, i is the word index and $EmbeddingMatrix$ is a matrix of shape containing the learned word embeddings.

The Bi-GRU augments the Gated Recurrent Unit (GRU) by processing data in opposite directions. Prior to exploring the Bi-GRU, we will examine the equations that govern a standard GRU.

For a single GRU cell, the following equations define its operation. Here z_t represents the update gate, r_t denotes the resent gate, σ signifies sigmoid activation function, $\tilde{h}_t$ stands the potential hidden state for the current node in the hidden layer, h_t is the hidden state at time t, and h_{t-1} is the input at time is the hidden state of the previous time step. w and u are weight matrices.

$$z_t = \sigma\,(w_{zx}x_t + u_{zh}h_{t-1}) \tag{2}$$

$$r_t = \sigma\,(w_{rx}x_t + u_{rh}h_{t-1}) \tag{3}$$

$$\tilde{h}_t = \tan\,(w_{hx}x_t + r_t * u_{hh}h_{t-1}) \tag{4}$$

$$h_t = (1 - z_t) * \tilde{h}_t + z_t * h_{t-1} \tag{5}$$

In a Bi-GRU, these operations are performed in two separate GRUs: one processing the sequence from start to end ($h_t^{forward}$) and the other from end to start ($h_t^{backward}$). The final hidden state (h_t) for each time step is a concatenation of these two directional hidden states:

$$h_t = [\,h_t^{forward};\ h_t^{backward}\,] \tag{6}$$

Each GRU in the Bi-GRU has its own set of parameters, and they are trained to capture temporal dependencies in both directions of the input sequence.

Following the Bi-GRU layer, the Conv1D layer applies a 1D convolution operation with $relu$ activation function applied afterwards. $K(u)$ embodies the value of kernel at position u and $I(i+u)$ is the input feature at position $i+u$.

$$F(i) = \sum_{u=0}^{Kernel\_size-1} I(i+u).K(u) \tag{7}$$

$$relu(x) = \max(0, x) \tag{8}$$

After that, max pooling operation was performed over the 1D input. For input feature map F, pooling size $poolsize$, and output feature map P, the max pooling operation at position (i) is:

$$P(i) = \underset{0 \leq u < poolsize}{max} F(i+u) \tag{9}$$

The Flatten layer simply reshaped the output to a single dimension. Dense layers performed linear transformation followed by $relu$ activation, with $L2\ Regularization$ applied to the weights w:

$$Flatten(F) = Reshape\ to\ 1D(F) \tag{10}$$

$$y = relu(w_x + b) + L2\ Regularization \tag{11}$$

To conclude the model, a sigmoid activation function was used to provide the probability of the text indicating suicidal ideation.

The proposed model's ability to understand both the context and specific language signs in social media data makes it suited for identifying potential signs of suicidal thought.

Beyond the proposed model, our study explored additional models to comprehensively analyze suicide risk, including:

2) CNN: Designited for its intriguing ability to detect local patterns and features in textual data [15]. The arhitecture consisted of a 100-dimentioal embedding layer to encode words, followed by a Conv1D layer with 128 filters of size 3 and for feature extraction ReLU activation function was applied. To prevent overfitting, the model included MaxPooling1D and Dropout layers. Other configurations remained similar to the proposed model. CNN model was utilized through the layers and parameters that are shown in Table III.

TABLE III. OPERATIONAL DETAILS OF CNN MODEL

Layers	Parameters	Values
Embedding	Embedding Dimension	100
Conv1D	Filters	128
	Kernel Size	3
	Activation Function	ReLU
MaxPooling1D	Pool Size	2
Output	Activation Function	Sigmoid

3) Bi-GRU: Chosen for its proficiency in capturing contextual information from text sequences in both forward and backward directions [16]. The Bi-GRU model also employs a 100-dimentional embedding layer simmilar to CNN and proposed model. It incorporated two BiGRU layers with 128 and 64 units and recurrent connections for bidirectional sequence processing. The dense and dropout layers, optimizer, loss function, batch sizes, and epochs are retained as in the CNN configuration. Table IV illustrates the values of parameters used in Bi-GRU model.

TABLE IV. OPERATIONAL DETAILS OF BI-GRU MODEL

Layers	Parameters	Values
Embedding	Embedding Dimension	100
Bi-GRU Layer	Units	128,64
	Dropout	0.25
	Recurrent Dropout	0.25
Output	Activation Function	Sigmoid

4) Linear Support Vector Classifier (Linear SVC): Employed for its effectiveness in binary classification of textual data. In our context, the below mentioned decision function was used to predict the new data points classes that were fed into the Linear SVC model.

$$f(x) = sign\ (w.x + b) \tag{12}$$

where, $f(x)$ is the decision function that determines the class of a new data point $x. sign(\ )$ function assigns a class based on the sign of the result.

5) Logistic Regression (LR): Applied due to its simplicity and efficiency in probabilistic prediction.[4] The LR model is suitable for binary classification tasks like distinguishing between suicidal ideation and general content in our datasets. This is achieved through the logistic function, formally represented as:

$$P(Y = 1|X) = \frac{1}{1+e^{-(\beta_0+\beta_1 X_1+\beta_2 X_2 \cdots\cdots \beta_n X_n)}} \tag{13}$$

Here, $P(Y = 1|X)$ is the probability that the dependent variable Y is equal to 1, given the independent variables $X. \beta_0$ is the intercept and e is the base of the natural logarithm. The prediction is typically classified as 1 (suicide class) if $P(Y = 1|X)$ is greater than 0.5, and as 0 (Non-suicide class) otherwise.

6) Decision Tree (DT): Chosen for its ability to understand complex language structures and relationships [17]. DT aids in suicide risk assessment through decision paths.

7) AdaBoost: Selected to enhance the performance of decision trees. The ensemble method combines multiple weak learners to form a strong classifier and improve the accuracy of suicide risk predictions from textual data [18].

The most representative equation for AdaBoost classifier is the final model decision function. It is a weighted sum of the weak classifier's decisions characterized as:

$$H(x) = sign(\sum_{t-1}^{T} \alpha_t \cdot h_t(x)) \tag{14}$$

In the equation (1.14), $H(x)$ represents the final decision function of the AdaBoost classifier and T is the total number of weak classifiers used. In this study, the value of T was specified as 50. α_t denotes the weight of the 't' th weak classifier in the ensemble.

As hyperparameter tuning, the parameters including batch size, epoch, optimizer, dropout rate, kernel size, and hidden units were systematically adjusted. After identifying the best combined parameters, the performance of all models was evaluated.

IV. RESULT ANALYSIS

Following precise pre-processing and data cleaning, the model training and evaluation phases proceeded. The process began by allocating 70% of the data for training, 20% for validation, and 10% for testing. This division was designed to rigorously assess model's performance and generalizability.

The procedure of result analysis initiated with Word clouds generation for each class. The word clouds provided a visual representation of word frequencies. They were created using the 'WordCloud' library for displaying words with sizes proportional to their frequency in the texts. This approach highlighted the most prominent words in larger fonts, allowing for easy identification of key terms characteristic of suicidal and non-suicidal texts. The clouds of each context for both datasets are shown in Fig. 4.

As this task primarily centered around DL techniques, performance of the DL models was examined and evaluated subsequently. Table V provides a detailed breakdown of evaluation metrices. For Reddit dataset, the proposed model exhibited the highest accuracy of 93.07%. Accrued F1-score of 0.93 indicates a balanced precision-recall relationship. The performance of the proposed model remained notable on the Twitter dataset as well, with an accuracy reaching 92.47% and mentionable precision and recall for both classes. With consistent performance against both datasets, the model establishes its strength in classification tasks.

In examining word embedding's influence on model efficacy, outcomes revealed the prominence of Skip-Gram method over alternative techniques such as CBOW and GloVe embeddings. This finding emerged as the most effective, leading the study for further analysis.

Fig. 4. Word clouds of a) Reddit b) Twitter.

TABLE V. RESULTS OBTAINED FROM DL MODELS

Data set	Models	Class	Precision	Recall	f1-score	Accuracy
Reddit	CNN	Suicide	0.92	0.91	0.92	91.30%
		Non-suicide	0.91	0.91	0.91	
	Bi-GRU	Suicide	0.93	0.92	0.92	92.12%
		Non-suicide	0.91	0.92	0.92	
	Proposed model	Suicide	0.93	0.94	0.93	**93.07%**
		Non-suicide	0.93	0.92	0.93	
Twitter	CNN	1	0.94	0.83	0.88	89.28%
		0	0.86	0.95	0.90	
	Bi-GRU	1	0.93	0.88	0.90	91.11%
		0	0.89	0.94	0.92	
	Proposed model	1	0.94	0.90	0.92	**92.47%**
		0	0.92	0.94	0.93	

On a different note, we operated two distinct optimizers: Adam and Stochastic Gradient Descent (SGD). The empirical findings indicated that the Adam optimizer continually outclassed SGD in terms of model's accuracy, securing its selection as the preferred optimizer. Table VI is showcasing the consequences.

TABLE VI. CHOOSING WORD-EMBEDDINGS AND OPTIMIZERS

Dataset	Methods	**Skip-Gram**		CBOW	GloVe
		SGD	**Adam**		
Reddit	CNN	90.85%	**91.30%**	90.52%	89.81%
	Bi-GRU	91.44%	**92.12%**	91.28%	90.75%
	Proposed Model	91.77%	**93.07%**	92.77%	92.36%
Twitter	CNN	88.25%	**89.28%**	87.34%	88.48%
	Bi-GRU	88.37%	**91.11%**	88.60%	89.17%
	Proposed Model	89.40%	**92.47%**	89.97%	90.19%

To obtain a deeper understanding of the capabilities of DL models, the accuracy-loss curve, confusion matrix and ROC curve were generated and inspected.

The ROC curves illustrated in Fig. 5 provides a visual representation of the ability of implemented classifiers to discriminate between suicide and non-suicide instances. Area under the curve (AUC) indicating the overall performance. Observing the outcomes, it is apparent that the proposed model demonstrates the highest discriminative power. The model reaches AUC values of 0.9797 and 0.9745 for Reddit and Twitter datasets, respectively. Being compared to the CNN and Bi-GRU models, performance of the proposed approach underscores the usefulness in capturing the complexities of both datasets.

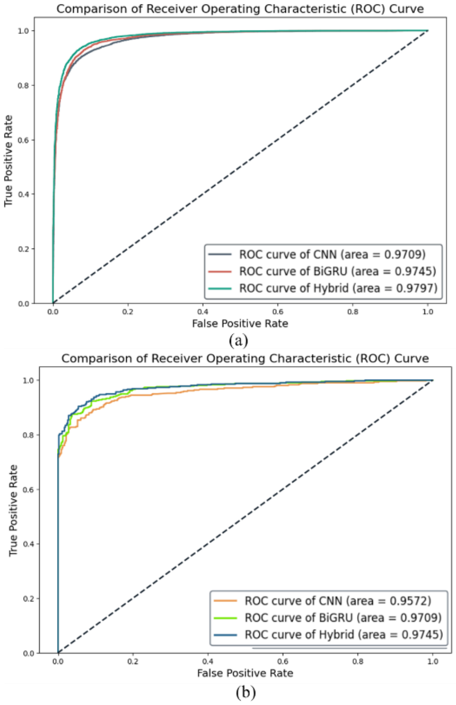

Fig. 5. ROC curves of (a) Reddit (b) Twitter.

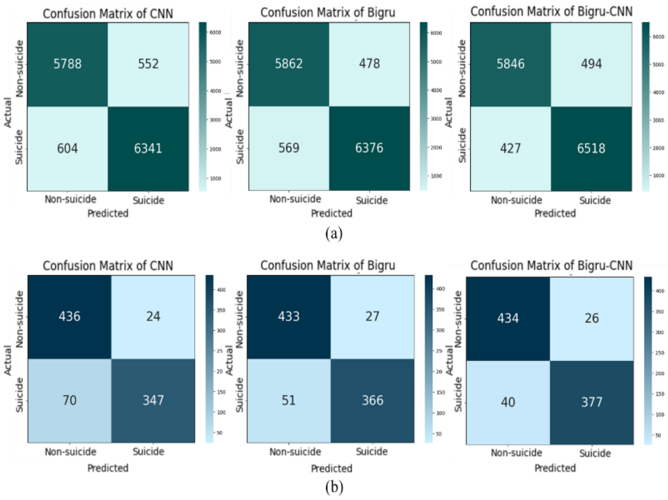

Fig. 6. Confusion matrices of (a) Reddit (b) Twitter.

We utilized confusion matrix to assess the effectiveness of our implemented models. The confusion matrix offers insights into true and false predictions and helps us understanding our model's performance. Derived metrics like precision, recall, accuracy, and F1-score gave a complete view of each model's capabilities and limitations. Fig. 6 showcases the confusion matrices for CNN, Bi-GRU, and BiGRU-CNN, starting from left.

In addition, the accuracy-loss curves in Fig. 7 and Fig. 8 guided the decision on when to stop training for avoiding overfitting. The early stopping technique was employed based on the validation loss. Here, the accuracy curve illustrated the percentage of accurate predictions in both training and validation phases. The loss curve indicated the extent to which the model's predictions differ from the actual values.

With the aim of further authenticating the performance of the models, a manual dataset was created containing twenty texts. The outcome is tabularized in Table VII that portrays five texts along with assigned labels and corresponding predicted labels by the models. The left most column of the table, indicates the dataset that the models were trained on prior to manual input testing. It is apparent to note that, the proposed model demonstrated comparatively satisfactory performance in this regard as well. The proposed model that was trained on the Reddit dataset was accurate in every prediction, whereas, Twitter trained proposed model predicted one suicidal text incorrectly.

Cross -dataset testing was executed to prolong the layers of rigorous scrutiny on model's resilience. To do so, models were tested by data they have not encountered during training. For instance, models trained on the Reddit dataset underwent testing against the Twitter test split and vice versa. The corresponding values presented in Table VIII revealed the proposed model's strong adaptability against the others.

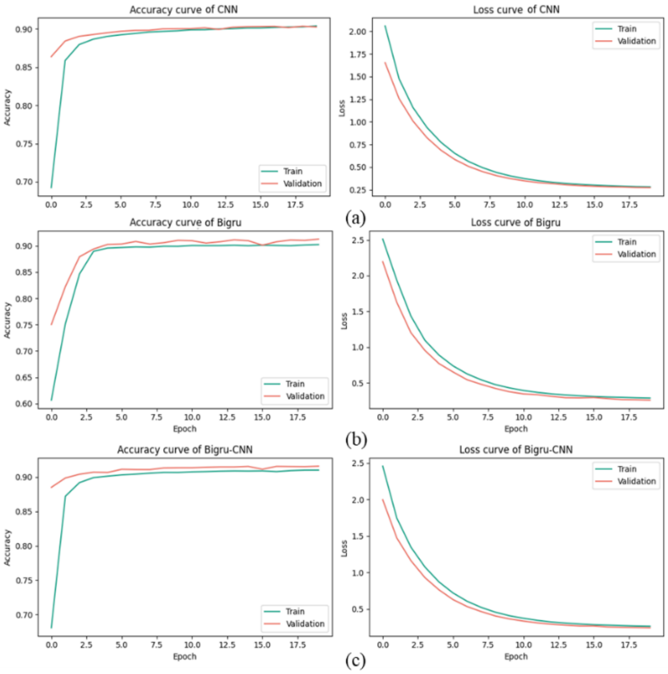

Fig. 7. Curves of (a) CNN (b) Bi-GRU (c) Proposed model of Reddit.

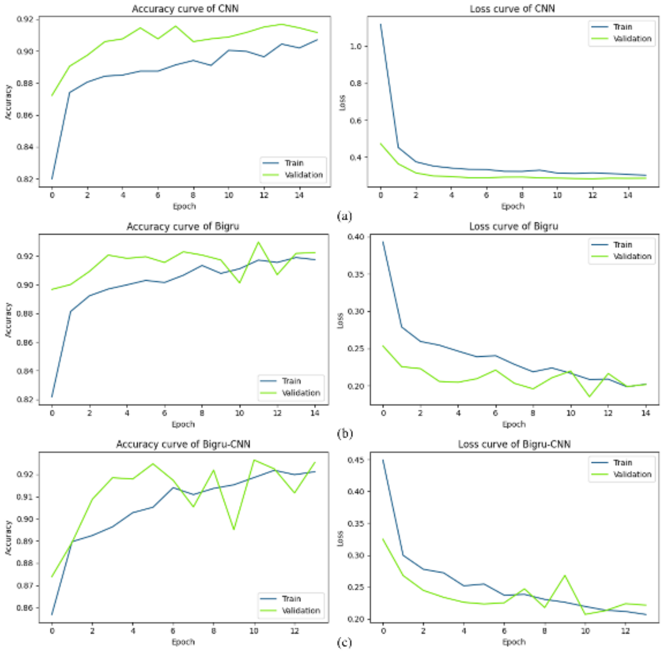

Fig. 8. Curves of (a) CNN (b) Bi-GRU (c) Proposed model of Twitter.

TABLE VII. PREDICTED RESULTS OF MANUAL INPUT TEXT

Trained On	Text	Actual Label	Predicted Label		
			CNN	Bi-GRU	Proposed Model
Reddit	Recommend pill to suicide	Suicide	Non-Suicide	Suicide	Suicide
	Don't tell me what to do. I am depressed	Suicide	Suicide	Suicide	Suicide
	The sun is shinning	Non-Suicide	Non-Suicide	Non-Suicide	Non-Suicide
	I want to end my life	Suicide	Non-Suicide	Non-Suicide	Suicide
	Going to commit suicide. No more toxicity.	Suicide	Suicide	Suicide	Suicide
Twitter	Recommend pill to suicide	Suicide	Non-Suicide	Non-Suicide	Non-Suicide
	Don't tell me what to do. I am depressed	Suicide	Non-Suicide	Suicide	Suicide
	The sun is shinning	Non-Suicide	Non-Suicide	Non-Suicide	Non-Suicide
	I want to end my life	Suicide	Non-Suicide	Non-Suicide	Suicide
	Going to commit suicide. No more toxicity.	Suicide	Suicide	Suicide	Suicide

As a final validation step to ensure model's reliability, K-fold cross-validation was implemented. The cross-validation determined the stability and consistency of models across multiple subsets of data.[5] This method systematically availed one-fold for testing and the rest for training and then averaged the results. The findings are structurally compiled in Table IX.

[5] https://machinelearningmastery.com/k-fold-cross-validation/

The data reveals a decline in accuracies with an increase in number of folds.

TABLE VIII. CROSS DATASET TESTING

Trained with	Tested By	Test Data Descriptions		Models Performance		
				CNN	Bi-GRU	**Proposed Model**
		Actual Class Distribution		Correctly Predicted Class		
Reddit	Twitter	0	460	246	274	319
		1	417	385	370	347
Accuracy				71.95%	73.43%	**75.94%**
Twitter	Reddit	Non-Suicide	6340	4228	4068	3994
		Suicide	6946	5209	5428	5593
Accuracy				71.04%	71.48%	**72.16%**

	Proposed Model	**91.72%**	**Proposed Model**	**89.64%**

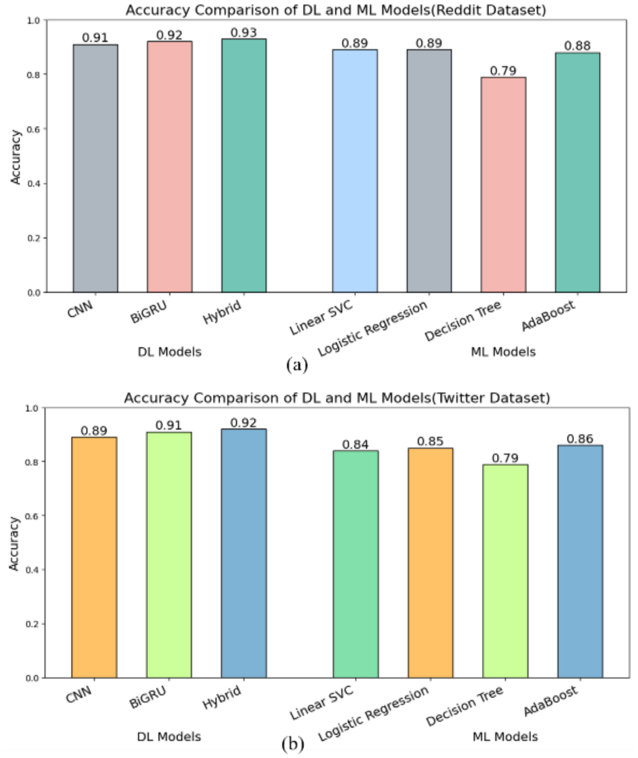

Fig. 9. Accuracy comparison among DL and ML of (a) Reddit (b) Twitter.

The research concluded with performing a comparative analysis of ML models to assess their respective effectiveness compared to Dl models. Therefore, four traditional ML models were accounted for. The performance analysis is visually portrayed with a bar chart presented in Fig. 9 which explicitly demonstrates the supreme accuracy of DL models for both datasets. It highlights the effectiveness of DL approaches over ML models in predicting suicidal contents.

A complete synopsis of the outcomes acquired from ML models, including evaluation metrices, is systematically tabulated in Table X.

TABLE X. RESULTS OBTAINED FROM ML MODELS

Data set	**Models**	**Class Label**	**Precision**	**Recall**	**f1-score**	**Accuracy**
Reddit	Linear SVC	Suicide	0.83	0.81	0.82	88.55%
		Non-suicide	0.91	0.92	0.92	
	LR	Suicide	0.84	0.80	0.82	88.55%
		Non-suicide	0.91	0.93	0.92	
	DT	Suicide	0.66	0.69	0.68	78.58%
		Non-suicide	0.85	0.83	0.84	
	AdaBoost	Suicide	0.82	0.81	0.81	87.97%
		Non-suicide	0.91	0.91	0.91	
Twitter	Linear SVC	1	0.77	0.92	0.84	83.69%
		0	0.91	0.77	0.84	
	LR	1	0.78	0.93	0.85	84.83%
		0	0.92	0.78	0.85	
	DT	1	0.77	0.80	0.78	79.36%
		0	0.82	0.79	0.80	
	AdaBoost	1	0.82	0.90	0.86	85.97%
		0	0.90	0.83	0.86	

The essence of findings from Table X indicates a decline in accuracy for most models on the Twitter dataset, however, the F1-score remained consistent for both classes. In contrast, the Reddit dataset, while displaying better accuracy, struggled to identify suicide class. When compared with the results presented in Table V, it is evident that DL models showcased higher competency over ML models.

V. DISCUSSION

Suicide has emerged itself as a global threat to humanity, demanding urgent actions and attentions to address the complex challenges it presents. As early identification of suicidal thoughts is the essential strategy to prevent suicide, our study aimed to detect suicidal tendencies by analyzing social media interactions. Pursuing that, we employed both ML and DL methods and assessed their performance. This study primarily emphasized on DL models while ML models were utilized for comparison. We conducted comprehensive pre-processing and experimented with several word embedding techniques. To verify the outcomes of the models, we utilized multi-source datasets. However, the length restriction of a tweet often proves inadequate for expressing an individual's complex emotions, which might be responsible for the slight performance decline of the models trained on Twitter dataset. We implemented various strategy to examine the generalizability of the models. Despite the notable outcomes of our work, the models possess limitations to assess the risk variables associated with suicide psychology. Pairing our findings with the statistical analysis of the psychologists could make these models a better indicator of suicidal thoughts.

VI. Conclusion

This research aimed to develop and evaluate a detection system to identify suicidal thoughts of individuals by analyzing their social media post. The study intended to reduce suicide rate by detecting suicidal thoughts in the social media interactions of the users. To accomplish this, textual data from Reddit and Twitter was collected and both ML and DL methods was utilized with a view to assess the psychological states of the users. Through meticulous evaluation and comparison of several ML and DL methods, the study has established the commendable predictive accuracy of the proposed model. The proposed model evidently captured the discrepancies of the data in a more effective manner. It evolved into the most proficient model for suicide detection by securing accuracies of 93.07% and 92.47% respectively, on Reddit and Twitter datasets. Subsequently, a manual dataset was created, cross-dataset testing strategy was introduced and cross-validation was performed for further analysis of the generalizing ability of the models. The proposed model showcased superior results in these regards as well. Hence, the hybrid BiGRU-CNN model was proposed as an effective tool for analyzing mental health from social media content to expose suicidal thoughts.

This research concludes by highlighting the proficiencies of the proposed hybrid model and indicating a strong potential for real-world deployment. The insights attained from this study ought to lead the way for future research directions and practical applications. This research contribution is a step forward in the integration of AI into mental health services. It aimed to provide strong foundation for future advancements in NLP and AI-assisted mental health monitoring.

VII. Future Scope

Regardless of promising outcomes demonstrated by the proposed model, there always remains scope for future development. Introducing the proposed model to more diverse data from social media platforms including Facebook and Instagram could significantly enhance the model's understanding, thus accuracy. Additionally, real-world testing through direct integration with social media could provide valuable insights into its reliability and competency in practical applications. Advanced pre-trained transformer models particularly BERT, ELECTRA, and neural networks such as HANN could be employed with a view to compare them against the proposed model. Given the sensitivity of the task at hand, continuous refinement and improvement are crucial to ensure the model's resilience and real-world impact.

Enhancing the Odia Handwritten Character and Numeral Recognition System's Performance with an Ensemble of Deep Neural Networks

Mamatarani Das[1], Mrutyunjaya Panda[2], Soumya Sahoo[3]
Department of Computer Science and Applications, Utkal University, Bhubaneswar, Odisha, India[1, 3]
Department of Computer Science and Engineering, C.V. Raman Global University, Bhubaneswar, Odisha, India[1, 2]

***Abstract*—Offline handwritten character recognition (OHCR) is considered a challenging task in pattern recognition due to the inter-class similarity and intra-class variations among the symbols present in the alphabet set. In this work, a learning-based weighted average ensemble of deep neural network models (WEnDNN) is proposed to classify the 10 digits and 47 characters present in the alphabet set of Odia language, an official language of India. To build the base model for the ensemble network (EnDNN), three suitable convolutional neural networks (CNN), are designed and trained from scratch. The WEnDNN's accuracy is increased by using a grid search approach to determine the ideal weight allocations to give to the top-performing model. The performance of the WEnDNN model is compared with several standard machine learning models, which take the non-handcrafted features extracted from the finely tuned, pre-trained VGG16 model and a combination of Gabor and pixel intensity values to create handcrafted features. On several benchmark handwritten datasets, including NITR Odia characters (OHCS v1.0), ISI Kolkata Odia numerals, and IITBBS Odia numerals, the performance of the proposed WEnDNN model is assessed and compared. The experimental results demonstrate that, in terms of recognition accuracy, the proposed approach beats other state-of-the-art approaches.**

Keywords—Odia language; ensemble learning; machine learning; Gabor features; CNN; DNN

I. Introduction

It is possible to recognize a symbol easily with our naked eye, but hard for a handwritten character recognition (HCR) model. To reduce this recognition gap between humans and models and to achieve human-like accuracy, handwritten character and numeral recognition (HCNR) systems have made significant advancements in recent years, with various approaches developed in different languages. These systems play a crucial role in applications such as document digitization, automatic form processing, and handwriting analysis. While numerous methods have been proposed to tackle this challenging task, researchers are more inclined towards deep neural networks (DNN). Deep Convolutional Neural Networks have proven their advantage in getting high performance in different applications of pattern recognition tasks when handling large data sets to extract features automatically.

Acquisition of character images, pre-processing, feature extraction, and classification make up the three major steps of the conventional OHCR workflow, and much research in this paradigm has concentrated on enhancing each of these steps. For instance, the feature extraction stage has advanced to the point that many researchers aim to create potent feature descriptors or vectors referred to as handcrafted in the literature. The basic goal of feature engineering is to design features that maximize patterns' separation from other classes while placing patterns from the same class close to one another in the feature space.

From the literature, in the late 1990s, study into the recognition of Odia characters began. The research community has paid a lot of attention to the most popular Indian scripts, Devanagari, Bangla, and Telugu, compared to Odia scripts. Natives of the Indian state of Odisha as well as its neighboring states, including West Bengal, Chhattisgarh, and Jharkhand, are fluent in Odia, a popular and official language of India. The necessity to digitize historical documents available in Odia literature inspires researchers to create Odia HCRs that have advantages for both business and society. The advancement of Odia OHCR needs to be enhanced to meet the requirements of real-time recognition. Modern schemes use features that are manually designed (handcrafted), which requires a lot of work. Several researchers have designed CNN based classification model to obtain deep features (non-handcrafted features) for Odia OHCR [1], [2]. In Odia language, most letters have a perpendicular straight line on the right side, while the upper portions are mostly circular. The characteristics of similar characters present as well as the roundish structure and the randomness of its writing, bring great challenge to the recognition task, which motivates us to propose an Odia OHCR model that enhances the classification accuracy in this regard.

The right selection of feature descriptors still presents the biggest hurdle in these OHCR systems. Utilizing a method known as “transfer learning”, those architectures are being employed for numerous applications all around the world. In this transfer learning method, the weights of a model that has already been trained for a particular job are used for a variety of tasks. Such architectures include VGG16 [3], ResNet, Xception, DenseNet, MobileNet, InceptionNet, ResNeXt etc. These architectures differ from one another in terms of depth, complexity, and size of input data. Despite having been trained on ImageNet 1000 classes, they are successfully used in all applications of pattern recognition tasks. According to Odia OHCR's related work[4], [5], the majority of researchers choose the model that performs better in terms of accuracy in classification. Although significant progress has been made in developing individual handwritten character and numeral recognition models, their accuracy levels often plateau or show diminishing returns with increased complexity. This limitation is primarily due to the inherent variability in handwriting styles, diverse character and numeral shapes, and the presence of noise and distortions in handwritten samples. Therefore, there is a need to explore alternative approaches that can enhance when solving a classical classification problem using various trained machine learning or deep learning models, the model that produces the best results is maintained and the other models are discarded. If all of the trained models are put together for classification, that will be a better option, as some models are good for extracting certain features while some other models are good for extraction of other kinds of features. An ensemble of different trained models can be used for this purpose. In the case of handwritten character recognition using Convolutional Neural Networks (CNNs), an ensemble of different CNNs often performs better than a single CNN for several reasons:

1) Each CNN model in the ensemble is trained independently on a different subset of the data or with different initialization weights. By combining their predictions, the ensemble can help to reduce bias and overfitting.

2) Ensemble learning can help reduce the impact of errors made by individual models. If one model misclassifies a particular handwritten character, other models in the ensemble may still correctly classify it. Through the combination of predictions, the ensemble can reduce the overall error rate and improve the final classification result.

3) Ensemble learning involves averaging the predictions of individual models. This averaging process helps to smooth out noisy predictions and reduce the effects of outliers. By leveraging the collective wisdom of multiple models, the ensemble can provide a more confident and accurate prediction.

4) Different CNN models may excel at capturing different types of features or have different strengths in recognizing certain patterns. By combining the strengths of multiple models, the ensemble can achieve a more comprehensive and discriminative representation of the handwritten characters, leading to improved classification performance.

Now, there is always the option to employ an ensemble learning method that boosts efficiency by using several CNN models for the same tasks. This has inspired researchers that utilize CNNs for the task of character recognition and to develop methods for ensembles of networks to enhance CNN performance. It has been observed from related work that although many efforts have been made in the area of Odia OHCR to improve the performance of the model, no work has presented the ensemble of various CNNs. These models even result in a further improvement in accuracy of about 1 to 2% across the models when combined with the ensemble of different CNN's methodologies outlined in the research. This motivation led us to the development of EnDNN and WEnDNN.

This paper presents a novel approach for offline Odia handwritten character and numeral recognition (OHCNR) by using an ensemble of deep neural networks and a weighted average ensemble of deep neural networks. Our main contributions to this research are as follows:

- Three CNN models are designed from scratch, from a simple to a slightly complex model, by varying the feature maps and number of layers, and these CNNs are combined to create the base model of the ensemble network (EnDNN).
- A grid search method is used to get the right combination of weights to be assigned to the best-performing model to construct a weighted average ensemble of deep neural network models (WEnDNN), to boost the ensemble networks' accuracy.
- Traditional ML models (Random Forest (RF), Support Vector Machine (SVM), k-Nearest Neighbour (kNN), and Extreme Gradient Boosting (XG-Boost) are used, which are trained on non-handcrafted features obtained from fine-tuned, pre-trained VGG16 model and handcrafted features extracted by Gabor filters, combined with pixel intensity values to create feature descriptor.
- The performance of the WEnDNN model is compared with the individual CNN, EnDNN and ML models to show the effectiveness of the proposed work and the models are verified using a set of benchmark Odia databases, namely ISI Image database, NITROHCSv1.0 and IITBBS numeral database.

Here is a summary of the remaining portions of the paper: Some of the most significant studies on deep learning for Odia and other language OHCNR tasks currently published in the literature is highlighted in Section II. Section III discusses the materials and methodology, which covers the description of DCNN models and their components. The datasets used for the proposed work are covered in Section IV and the proposed model architecture is covered in Section V. Section VI reports the results and discussion, and Section VII provides the conclusion.

II. Related Work

In the Odia script, like every other script vowels, consonants, and composite characters (combinations of characters with other characters) are present. A total of 10 numerals and 47 alphabets (vowels and alphabets) are present in the Odia script, as shown in Fig. 3(a), 3(b), and 3(c). With different handwriting styles and high similarity between different characters, it's challenging for any system model to get human-like accuracy. Several works on Odia OHCR were reported in [6], [7] based on handcrafted feature extraction. In [8], authors have used curvature features and reduced the feature set by PCA and with quadratic classifier got a classification accuracy of 94.6%. In [9] Binary External Symmetry Axis Constellation (BESAC), features are used with an accuracy of 95.01 by the k-NN classifier. The authors of

[10] used zone centroid distance and standard deviation to extract features and got 94% accuracy by back propagation NN with a genetic algorithm approach. [11], [12], [13]–[15], [16], [17][18] had contributed their work on handwritten Odia handwritten numeral recognition (Odia OHNR). The same BESAC features are used for numeral classification, on the IITBBS numeral dataset [9]. In [19], the authors achieved an accuracy of 95% by SVM with directional features by zoning method. In a work of [20], authors used Gradient, curvature feature, and Feature reduction using PCA fed to low complexity neural classifier for recognition with an accuracy of 98% by gradient feature and 94% by curvature feature. In [16], the DCT and DWT coefficients are used by the BPNN classifier. Several studies have been reported on the ISI numeral dataset [21][22], [23] with a promising accuracy of over 90% for handwritten Odia numeral recognition.

The goal of researchers is to increase the optical character recognition (OCR) model's accuracy, so they are more focused on deep neural networks and ensembles of networks. To the best of our knowledge, almost little efforts on deep neural networks were contributed to the field of Odia OHCR and OHNR. In [24], the authors proposed RNN and CNN-based classification techniques for Odia compound characters. To improve the classification accuracy, different augmentation techniques were used by [1] to expand the dataset, and different CNNs were used for the classification of Odia handwritten numerals and characters. Different deep learning-based classification models proposed for Bangla OHCR, a sister language of Odia. In [25], the authors used mobilenet v1 architecture, whereas the authors [26] proposed a hybrid Bangla OHCR model that is a combination of stacked Bi-directional Long Short-Term Memory (Bi-LSTM) applied on the features extracted from CNN. A deep analysis was carried out by [27] for Bangla OHCR by different deep networks i.e. InceptionResNetV2, DenseNet121, InceptionNetV3, NASNet, VGG16, VGG19 and authors claimed InceptionResNetV2 as the best performing model. An improved CNN based digit recognition on MNIST dataset with an accuracy of 99.87% by [28].

Combining CNN models into an "ensemble" is one strategy for improving the handwritten character recognition system's accuracy. For the Odia OHCR, very few works based on ensemble networks were published. Three ensemble learning methods (AdaBoost, Bagging, and Random Subspace) are utilized in the study[29], for improved sentiment analysis and in [30]different features were selected and classified using Random Forest, which is an ensemble of several decision trees for Odia vowel recognition. The authors of [31] reported an offline Tai Le OHCR using ensemble deep learning, with a DCNN serving as the primary or base classifier. An ensemble deep learning model is created by stacking several different base classifiers, and the model achieves an accuracy of more than 98% on the Devanagari handwritten characters and MNIST handwritten digits datasets. The base classifiers' parameter combinations are optimized using a grid search technique.

Apart from OCR applications, ensemble networks were used in different fields [23]-[27], and some of the applications are described below. A deep ensemble network by using LSTM-B was proposed by [32] to obtain the accurate results of exchange rates forecasting and to improve the profit of exchange rates trading. The authors of [33] proposed a deep ensemble learning algorithm on a variety of datasets, including those for letter recognition, cancer, diabetes, heart disease, thyroid, etc., which determines the ensemble size, the number of hidden nodes in a neural network, etc. In [34] the authors used CNN as an ensemble model for object detection by selecting the region from each CNN model is combined, classified, and finally voted. Automated audio classification is proposed by [35] that fuses different types of features extracted from audio files and uses different pre-trained CNN models AlexNet, GoogleNet, VGG16, VGG19, ResNet50, InceptionV3 as ensemble and got the maximum accuracy of 99.3% by using ensemble DL and handcrafted features. In [36], the authors used an ensemble model for crash prediction model using road geometric alignments (CPM-GA) with three traditional models NB model and IHSDM-China and IHSDM-US models, and CART+SVM, RF + SVM, CART + BPNN, RF + BPNN as base models of the ensemble by selecting the model by model prediction test and model’s sensitivity test. The results of the ensemble learning CPM-GAs using the IHSDM + China model and CART + SVM model are promising. Due to their improved accuracy, increased robustness, and scalability in model design for character recognition, ensemble models are becoming more and more popular nowadays. Utilizing ensemble data mining techniques for the classification of skin diseases is reported in [42][43]. It explores methods to enhance accuracy and reliability in diagnosing skin conditions through ensemble data mining techniques. To improve optical character recognition (OCR) performance by employing an ensemble of Support Vector Machine (SVM), Multi-Layer Perceptron (MLP), and Extra Trees classifiers is shown in [44]. An ensemble model composed of Convolutional Neural Networks (CNNs) for classifying cloud image patches, particularly on small datasets addresses the challenge of achieving accurate classification results with limited data and is proposed in [45].

III. Materials Used

This section discusses all the materials and methodologies that are utilized to construct the proposed ensemble model of deep neural networks.

A. Deep CNN Models

Due to the non-linear behavior of neural network models, CNNs can learn the complex nonlinear relationships in the given input data. Convolutional layers, pooling layers, and fully connected dense layers are the three fundamental layers that make up the conventional CNN structure. These layers are repeated to make an NN to a deep CNN, and it is shown in Fig. 1.

Fig. 1. Basic structure of a deep convolutional neural network.

1) Convolutional layer: These layers identify patterns in images by sliding a filter over the input image to produce a feature space or feature map. If the input image is directly connected to the fully connected layer for classification, we may get the result, but the complexity increases when the input image size is large and the number of images is greater. The expensive computation and the cost reduction can be achieved by including the convolution and pooling layers. The basic convolution operation in convolutional layer is represented mathematically in Eq. (1), where f (x, y) is the input image, c (x, y) is the convolved image and h (x, y) is the filter or kernel.

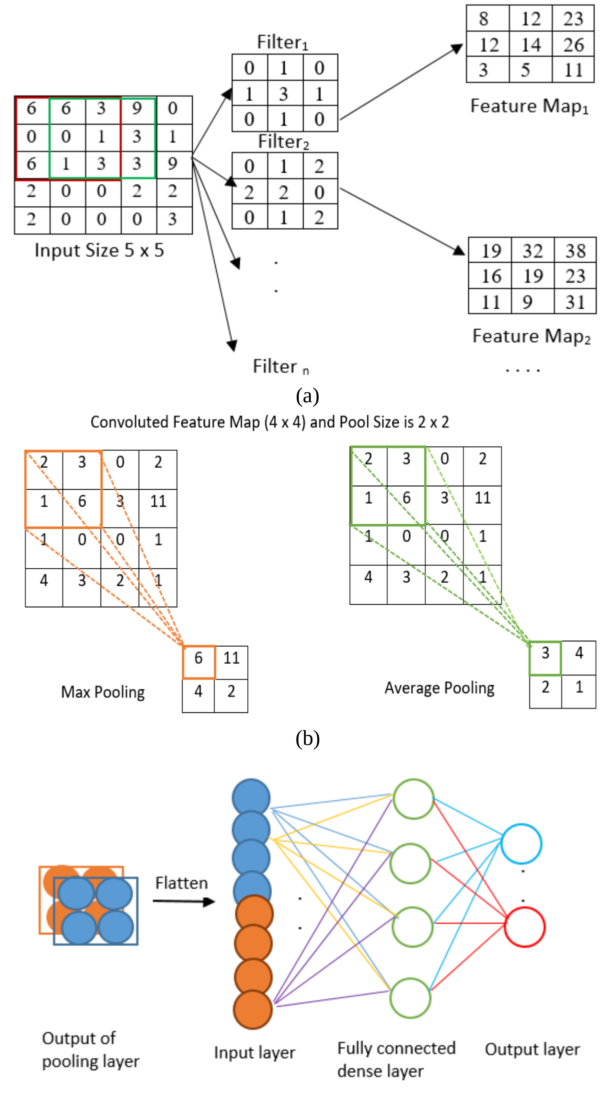
$$\boldsymbol{c}(\boldsymbol{x},\boldsymbol{y}) = \boldsymbol{h}(\boldsymbol{x},\boldsymbol{y}) * \boldsymbol{f}(\boldsymbol{x},\boldsymbol{y}) \qquad (1)$$

The advantage of CNN can be taken to extract important features by reducing the image dimension and keeping important features for better prediction. It learns images by applying a filter of a certain size while maintaining translation invariance, in addition to learning the features from the data. The convolutional layer has several learnable filters, each of which can be thought of as a matrix. The convolutional layer produces numerous feature maps (also known as activation maps), and these feature maps corresponding to distinct filters are layered together along the depth dimension. Each member of the matrix or filter serves as a parameter (weight and bias) of neural networks. The convolutional layer's operational structure is shown in Fig. 2(a).

The basic component of a convolution operation in a convolutional layer is the kernel. The features or significant patterns in an image are extracted from the image using a filter called a kernel. It is a matrix $\boldsymbol{h}(\boldsymbol{x},\boldsymbol{y})$ that traverses the input image $\boldsymbol{f}(\boldsymbol{x},\boldsymbol{y})$, performs a dot product with the sub-region of the input data, and produces the matrix $\boldsymbol{c}(\boldsymbol{x},\boldsymbol{y})$ of values from the dot product. To obtain another value in the feature map, the kernel moves the input image by a stride value.

2) Pooling layers: This layer down-samples the features in the feature map by reducing their dimension. It also introduces translation invariance, i.e., even if the CNN input image is translated, the CNN will still be able to recognize the features, which reduces the CNN model's tendency to overfit data. The quantity of network computation and the number of parameters to learn are both decreased by the pooling layer. The two most common pooling methods are max-pooling and average pooling, as shown in Fig. 2(b). The most prominent patterns of the feature map are retained as a result of max pooling, and the resulting image is sharper than the original. Max pooling operates by choosing the maximum value from each pool. By averaging the pool, the average pooling layer operates and it smooths the image by maintaining the image feature's essential qualities.

3) Fully connected dense layer: A dense layer is one whose interior neurons are connected to every neuron in the layer preceding to it. Finally, it is connected with the number of units, the same as the number of classes, and produces output. A CNN model employs one or more FC layers following a series of convolutional, ReLU, or pooling layers to produce the output. The way FC layer works is similar to how classic neural networks work in that it combines all of the features that the earlier layers have acquired in order to find more important patterns. The main issue with the fully connected layer is that it has a lot of trainable parameters and requires a lot of computation to train. Therefore, current research efforts are concentrated on either lowering these layers or substituting methods that may accomplish the same purpose with less computational effort for the layers. A soft-max function is utilized to determine the class label by giving each class a probability distribution after the final FC layer. The operational structure of a fully connected layer is shown in Fig. 2(c).



(a)

(b)

(c)

Fig. 2. (a) The basic operational structure of the convolutional operation. (b) The basic operational structure of pooling. (c) The basic operational structure of fully connected layer.

4) Rectified Linear Unit (ReLU) Activation: After the convolutional layer, the ReLU layer is frequently used, which introduces non-linearity to the output. All negative input values are mapped to zero in this layer, R (I) = max (0, I), and its operation is denoted by the following Eq. (2):

$$\mathrm{R(I)} = \begin{matrix} \mathrm{I} & \text{if } \mathrm{I} \geq 0 \\ 0 & \text{otherwise} \end{matrix} \quad (2)$$

ReLU activation function has several advantages, including computing efficiency, quicker convergence than non-linear functions like sigmoid and tanh, and protection against vanishing gradient issues.

5) Softmax activation: The activation function known as softmax, scales numbers into probabilities that generate a vector V with probabilities for each class. The sum of all output values in the V adds up to 1. It is defined in Eq. (3), where y is the vector of possible outcomes of n elements for n classes, is input to the softmax function and y_j is the j^{th} element of vector y.

$$\mathrm{softmax}(y)_j = \frac{e^{y_j}}{\sum_{k=1}^{n} e^{y_k}} \quad (3)$$

6) Cross-entropy as loss function: The cross-entropy loss quantifies the dissimilarity between the predicted class probabilities and the actual class labels. It penalizes the model for assigning low probabilities to the correct class and assigning high probabilities to incorrect classes. The loss value is larger when the model's predicted probabilities deviate further from the true expected values. During the training process, the model's weights are adjusted to minimize the cross-entropy loss. By iteratively updating the weights using techniques like gradient descent, the model learns to improve its predictions and reduce the loss. As the model gets better at classifying the handwritten characters, the loss decreases. Cross entropy is defined in Eq. (4), where t_j is the true label and p_j is the class probability value computed by the softmax activation function for class j.

$$CE = -\sum_{j=1}^{n} t_j \log(p_j) \quad (4)$$

IV. Databases

A benchmark database is necessary for any text recognition research to be successful. For efficient classifier or recognizer training, large databases are needed. The accuracy of recognition is entirely dependent on the type of feature extractor employed and the number of training samples taken from the database because of cursive scripts and various handwriting styles. The databases used for our study are shown in Table I, and sample images from the databases are shown in Fig. 3. The NITROHCSv1.0 data set is publicly available on the NIT Rourkela website, IITBBS numeral, and ISI image database will be available on request. These three databases are only available to the research community on the handwritten character recognition of the Odia language.

TABLE I. Handwritten Odia Character and Numeral Datasets

Database	Training Size	Testing Size
ISI Image Database	4,970	1,000
IITBBS Numeral Database	4,000	1,000
NITROHCSv1.0	10,528	4,512

1) ISI image database: An isolated database of handwritten Odia numerals was created in 2005 by [37] at ISI Kolkata, India. There were precisely 356 participants in the data collection procedure. It has 5,970 samples that were gathered via 166 application forms, and 105 pieces of mail, and the remaining samples were personally collected. The data set is then split into a training set and a test set, consisting of 4,970 samples and 1,000 samples, respectively. Sample numeral images of the ISI Image Database are shown in Fig. 3(a).

2) IITBBS numeral database: A new database for Odia numerals has been discussed by the authors [38] at the IIT in Bhubaneswar. At 300 and 600 dpi, the images were scanned. The IITBBS numeral database now has 5,000 handwritten examples of Odia numbers, and the database contains 10 classes and the sample numeral images are displayed in Fig. 3(b).

3) NITR OHCSv1.0 character database: Databases are also created and defined at NIT Rourkela by [39], which contains an Odia alphabet with 47 classes. There are 15,040 samples of atomic characters from the Odia language in the OHCSv1.0 database, each class contains 320 images. Data collection, picture enhancement, and size normalization are the procedures used in the construction of the database using the Odia character set. The database is split into 70:30 ratios for train and test sets. The total number of images in the train and test set is 10,528 and 4,512. Fig. 3(a) represents Odia character images of the NITR OHCSv1.0 database.

V. Methodology

The following are the steps of the experimental environment for the Odia handwritten character and numeral recognition model (OHCNR), which is shown in Fig. 4.

- Load handwritten images from the training and test sets.

- Convert the images to grayscale.
- Normalize the pixel values of the grayscale images to a range of 0 to 1. This enhances the training of the neural network (NN) model.
- Design three CNNs as base models for the Ensemble Deep Neural Network (EnDNN).
- Construct the EnDNN by integrating the three designed CNNs.

Select the right combination of weights by the grid search method to be assigned to the best-performing model to construct WEnDNN.

1) Designed CNN models as base model for EnDNN: To achieve high recognition accuracy, a character and numeral classifier based on a convolutional neural network (CNN) is used. Convolutional, max-pooling, fully-connected, and softmax layers are used in the construction of three different CNN-based handwritten digit classifiers. Additionally, the training is carried out utilizing the back-propagation method with mini-batches of size 28 and the adam optimization methodology. When an image is processed for a character recognition task, the crucial features are retained in the convolution layers, intensified, and maintained throughout the network, while the irrelevant information is eliminated by the pooling operation. Fig. 5 lists the parameters utilized in all three created CNN classifiers, each of which has a distinct number of convolutional layers, kernel sizes, filters, and strides.

For instance, the CNN1 depicted in Fig. 5(a) contains one output layers of 10 classes, 2 max pooling layers, 3 convolutional layers, and 1 fully-connected layers. The size of kernel, stride value, and number of filters in the first convolutional layer are 3 x 3, 1, and 32 with an activation function ReLU. For down sampling, pool of size (2,2) is applied in max-pooling layer, next to convolutional layer to reduce the dimensions with a dropout value of 20%. The second convolutional layer of filter size (3,3) and 64 number of filters are used with a dropout value of 20%. 128 filters with a (3,3) filter size are put in the third layer. Next the feature map is flattened to create one dimensional feature vector and one fully-connected dense layers are used, which are connected with 10 output classes. To calculate the class probabilities for three CNN models, ReLU activation function is utilized in the hidden layer and softmax activation function is used in the output layer. Categorical cross entropy is used as the loss function, and iteratively updating network weights based on training data is done using the adaptive moment estimation (adam) optimization method. The input images are fed to the network taking 28 images as a batch at a time and epoch size is 10. In Fig. 5(b) and 5(c), the other two classifiers' convolutional, max pooling, and fully connected layer counts with activation functions are displayed.

a) Steps of the recognition process by CNN: The handwritten characters and numeral recognition process, using a Convolutional Neural Network (CNN), typically involves the following steps:

i) Data Acquisition: Collect Odia handwritten dataset

ii) Data Split: Creating training and test sets from the dataset. The model is trained using the training set, and its performance is assessed using the test set.

iii) Pre-processing: Applying pre-processing techniques to the images in both the training and test datasets like resizing the images to a consistent size, applying image enhancement techniques, and normalization.

iv) Data Normalization: Normalizing the pixel values of the images so that they range from 0 to 1. This step helps in improving the convergence of the neural network during training and ensures that all features have a similar scale.

v) Batch Training: Dividing the training dataset into batches of a suitable size. Batch training involves feeding a subset of the training data to the network at a time instead of using the entire dataset in one go. This approach facilitates efficient computation and allows the network to update its weights based on smaller subsets of data at each iteration.

vi) Model Training: Training the CNN model and its variants using the labelled training data. This step involves feeding the batches of training images to the network, performing forward and backward propagation, and adjusting the network's weights using optimization techniques like gradient descent. The training process aims to minimize the difference between the predicted output and the actual labels.

vii) Classification: Using a trained model to classify new, unseen images. This involves passing the test images through the trained network and obtaining predictions for each image. The predicted labels are compared to the true labels to evaluate the model's accuracy.

viii) Performance Analysis: Analysing the recognition accuracy and processing time for all the variants of the trained model. This step includes calculating metrics such as accuracy, precision, recall, and F1 score to assess the model's performance. Processing time can be measured during both training and classification phases to evaluate the efficiency of different model architectures and training strategies.

2) Ensemble of Deep Neural Networks (EnDNN): Ensemble is the process of combining several learning algorithms to improve the performance of existing models by combining different models into a single reliable model. There is now always the choice to use an ensemble learning approach, which increases efficiency by applying a number of CNN models to the same tasks. By training numerous models instead of just one and combining their predictions, neural network models can successfully reduce their variance. So, the ensemble learning method, not only lowers the variance of predictions but also has the potential to produce predictions that are superior to those produced by a single model.

In a CNN, the produced output probabilities are o1, o2, o3 .. on, where $\sum o_i = 1$, for an unseen image x of n-class classification, the CNN determines the unseen image x belongs to the class i with the greatest likelihood probability oi. In our study, the proposed CNNs should provide a probability value to each unseen test image that it was labelled by either of the 10 numerals for numeral recognition or 47-character classes for character recognition. Class probabilities for each image, derived by the individual CNN's, will be the input of our ensemble of networks and the ensemble algorithm is shown in Algorithm 1. Every individual model will make a prediction based on the test data. The ensemble approach combines the predictions of the three CNN models by summing their predicted probabilities and selecting the class with the highest summed probability as the final prediction.

Algorithm 1: EnDNN: The algorithm evaluates the performance of three designed CNN models individually and an ensemble of the three models by comparing their predicted labels with the true labels.

```
1. Load the dataset of Odia character or numeral images along
   with their corresponding class labels.
2. For each image in the dataset:
       • Apply pre-processing techniques such as
         resizing, RGB to Gray conversion and
         normalization.
3. Define three sets of convolutional neural network (CNN)
   models as the base models for the ensemble. (The
   architecture of each model is defined in Section 5)
4. Split the pre-processed dataset into training and test sets.
       • For each base model in the ensemble:
           ▪ Train the model on the training set using adam
             as an optimizer and categorical – cross entropy
             to compute loss.
           ▪ Evaluate the model's performance on the test
             set to measure its individual recognition
             accuracy.
           ▪ Save these models as CNN1, CNN2, CNN3.
5. Load these pre-trained models: CNN1, CNN2, CNN3.
6. For each model in the list of models, do the following:
       • Predict the output for the test data and store the
         predictions in the prediction list.
7. Sum the prediction probabilities of each test image for each
   class obtained from different models of ensemble DNNs.
8. Determine each test image's maximum class recognition
   accuracy from the summed prediction values of an
   ensemble of DNN as ensemble accuracy:
       • For each test image in the dataset:
           ▪ Determine the class or category with the highest
             summed prediction value.
           ▪ Compare this prediction with the ground truth label
             of the image.
           ▪ Calculate the ensemble accuracy by measuring the
             percentage of correctly recognized test images
```

3) Weighted ensemble of DNNs (WEnDNN): Since deep learning models differ in architecture and complexity, not all of them produce the same outputs; some produce superior output than others. To get the maximum output from any model, it would be beneficial if we gave larger weights to the better-performing models. Weighted ensemble learning is a variation of ensemble learning where different models in the ensemble are assigned different weights to determine their contribution to the final prediction. In the case of handwritten character recognition using a weighted ensemble of different CNNs, it can perform better because assigning different weights to individual CNN models allows the ensemble to emphasize the strengths of each model. Certain CNN models may be particularly effective at recognizing specific types of handwritten characters or capturing certain features. Models that consistently produce more accurate predictions can be assigned higher weights, while models with lower accuracy can be assigned lower weights. By assigning higher weights to these specialized models, the ensemble can benefit from their expertise and improve the classification accuracy for the corresponding classes.

Finding the ideal mixture of model weights is the issue in this situation, and the grid search method is employed to achieve this. To determine the best weight, various weight combinations were tested. The search procedure will continue until it has checked every combination, at which point the algorithm will give us the ideal weight combination that maximizes accuracy. We multiply the output probability values $output_{ij}$ of CNN_j (i =1,2 and 3) by $\omega eight_j$ (j = 1,2, and 3) after determining the appropriate weights for all the individual CNNs, and the class probabilities are calculatedwe using the weighted output probability values $\omega eight_j output_{ij}$ instead of the original output$_{ij}$ ones. The weighted ensemble algorithm is shown in Algorithm 2.

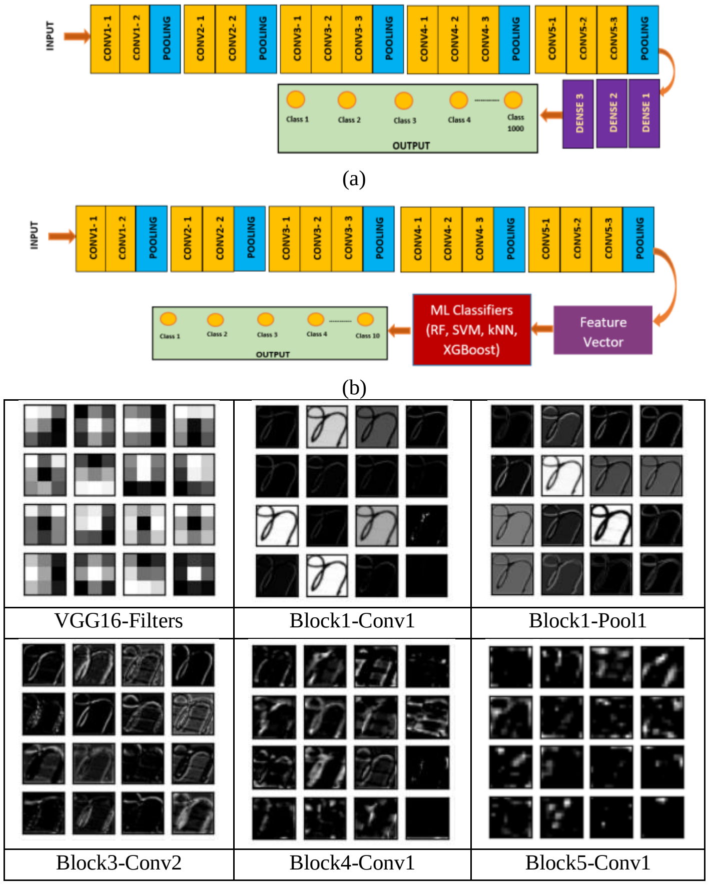
Algorithm 2: WEnDNN: This algorithm outlines the steps involved in generating predictions using an ensemble of DNNs with different weighting schemes and evaluating the accuracy of the weighted ensemble predictions on the test data.

1. Create a list for an ensemble of models, called models, and add the models (CNN1, CNN2, and CNN3) to it.
2. Initialize equal weights for each base model in the ensemble.
3. For each model in models, do the following:
   - Predict the output for each image in test set and store the predictions in the predictions list, where each base model’s prediction should be weighted equally at the start.
     predictions ← [prediction1, prediction2, prediction3]
4. Generate different combinations of weights for the base models in the ensemble.
   weights ← [weight1, weight2, weight3]
5. For each possible weight combination, multiply each prediction by its corresponding weight.
   weighted_predictions ← *prediction$_i$* * *weight$_i$*, where i = 1,2,3
6. For each test data instance, determine the weighted ensemble prediction by selecting the maximum value among the weighted predictions.
   - Combine the predictions from different models and choose the prediction with the highest weighted value. *weighted_ensemble_prediction←maximum (weighted_prediction)*
7. Compare the weighted ensemble predictions to the ground truth labels of the test data.
   - Calculate the accuracy of the weighted ensemble by measuring the percentage of correctly predicted instances.

4) OHCNR model with deep and hand-crafted features: In order to evaluate the performance of the proposed OHCNR model, two more experiments were carried out by extracting deep features using a pre-trained VGG16 model and handcrafted features from Gabor filter that captures texture features and pixel-level features from the images and use these features to train and test machine learning models for recognition purpose.

a) Extraction of deep features from pre-trained VGG16 model: The researchers use a variety of strategies to extract the pertinent features, whether handcrafted or non-handcrafted. Automatic feature extraction techniques have grown in popularity in recent years for solving character recognition problems due to their capacity to extract robust features. For non-handcrafted feature extraction, transfer learning techniques have recently been applied. A learned model for one problem is used for solving another problem, a process known as transfer learning. Diverse pre-trained models, including VGG16 (Visual Geometry Group), VGG19, InceptionV3, MobileNetV2, Resnet50, ResNetV2, Xception, DenseNet, etc., are used in transfer learning. The weights of the pre-trained models are used for the training process for the new problem. These pre-trained models are used for classification tasks, stand-alone or integrated feature extraction processes, and weight initialization. These non-handcrafted features are fed to RF, SVM, kNN, and XG Boost to train these models and compare the results with the proposed state-of-the-art model.

Data from a subset of the ImageNet dataset, which consists of over 14 million photos organized into 22,000 classes, was used to train a DCNN variation called VGG16 [3]. The VGG16 Model has 16 convolutional layers and, 5 max pooling layers connected to convolutional layers of 5 different blocks, 3 dense layers for the fully-connected layer, and an output layer with 1,000 nodes. The model architecture of VGG16 is shown in Fig. 6(a). To extract the deep features from the handwritten character image can be possible by removing the last few layers (fully connected layers) from the VGG16 model, as they are specific to classification, and retaining the convolutional layers, and its architecture is shown in Fig. 6(b). The filters of size (3,3) is used at different layers to extract deep features automatically. The filters and extracted features after layers Block1-Conv1, Block1-Pool, Block3-Conv2, Block4-Conv1 and Block5-Conv1 by VGG16 model for the Odia digit 3 is shown in Fig. 6(c).



(a)

(b)

(c)

Fig. 6. (a) VGG16 Model architecture. (b) Deep feature extraction from VGG16 model. (c) Extracted features at different layers of VGG16 model.

b) Extraction of hand-crafted features using Gabor filter bank, pixel intensity values: According to the literature, the feature extraction stage of OCR is the one that most heavily influences any system's accuracy among all other OCR stages. Different hand-crafted features that can be extracted from an image are structural or geometrical features. Either the entire image or the features that were taken from it serve as the input to any OCR. An image is made up of high-frequency components that originate from the edges, or the sudden changes in intensity values, and low-frequency components that make up the image's smooth sections. Any image must be transformed into a specific domain to be analyzed. In [40], to extract the discriminant features from a picture, image transformation is an essential step. Gabor filters are typically employed in texture analysis, edge detection, feature extraction, and other aspects of image processing and computer vision since they are independent of light, rotation, scale, and translation. They also infer optimal localization, making them a strong candidate for feature extraction issues.

In our study, 2D Gabor filter bank [41] is used. It is a sinusoidal plane with a certain frequency and orientation that is modulated by a Gaussian envelope is known as a 2D Gabor filter. The Gaussian component provides the weight, and the sine component provides the directionality. By using the Gabor filter, a bank of filters that can be used to detect and extract textures present in an image are created. The Gabor filter has a real and an imaginary component, as shown in Eq. (5), (6), and (7).

$$g(x, y; \lambda, \theta, \psi, \sigma, \gamma) = exp\left(-\frac{x'^2 + y'^2}{2\sigma^2}\right) exp\left(i\left(2\pi\frac{x'}{\lambda} + \psi\right)\right) \quad (5)$$

The real part and imaginary parts are represented as:

$$g(x, y; \lambda, \theta, \psi, \sigma, \gamma) = exp\left(-\frac{x'^2 + y'^2}{2\sigma^2}\right) cos\left(i\left(2\pi\frac{x'}{\lambda} + \psi\right)\right) \quad (6)$$

$$g(x, y; \lambda, \theta, \psi, \sigma, \gamma) = exp\left(-\frac{x'^2 + y'^2}{2\sigma^2}\right) sin\left(i\left(2\pi\frac{x'}{\lambda} + \psi\right)\right) \quad (7)$$

Where,

$$x' = xcos\theta + ysin\theta \ and \ y' = -xsin\theta + ycos\theta$$

The parameters are (x, y) is size of the kernel, σ is the standard deviation or sigma of the Gaussian envelope, ψ is the phase offset, θ is the orientation of the Gabor function, γ is spatial aspect ratio and λ is the wavelength of sinusoidal component. These five parameters determine the magnitude and shape of the Gabor function shown in Table II. By adjusting these parameters, a variety of Gabor filters can be applied to extract relevant characteristics from an image.

In our study, a bank of Gabor filters with a constant frequency for various standard deviations (1.5, 2, 2.5) and orientation values ($\frac{\pi}{4}$, $\frac{\pi}{2}$, $\frac{3\pi}{4}$), are created to extract features. For every handwritten image, nine Gabor filters (GF) are created which are convoluted on original image to get the filtered image. The largest response occurs at edges and locations where texture changes when a Gabor filter is applied to an image. Also, the pixel intensity values are included to the handcrafted feature descriptor (HFD) as shown below:

$$HFD = Pixel_{value}, GF_1, GF_2, GF_3, GF_4, GF_5, GF_6, GF_7, GF_8, GF_9$$

The sample two numeral images (0, 3) and character images (ma, pa) and their transformation following the application of the filter are shown in Fig. 7.

TABLE II. GABOR KERNEL PARAMETERS

Gabor Kernel Parameters	Purpose
Sigma (σ)	Determines the total size of the Gabor envelope. The envelope grows to allow more stripes when the bandwidth is bigger, and it shrinks when the bandwidth is smaller.
Aspect ratio (γ)	Determines the height of the Gabor function, height increases at very low gamma values and falls at very high aspect ratios.
Theta (θ)	Determines the Gabor function's orientation. Theta at $\frac{\pi}{2}$ and 0 degree represents the horizontal and vertical positions of the Gabor function.
Wavelength (λ)	It controls the strips' width. When the wavelength is lowered, stripes are thinner; when the wavelength is increased, stripes are thicker.
Phase offset (ψ)	Varying the phase offset can help in detecting edges or texture patterns in different orientations and locations within an image.

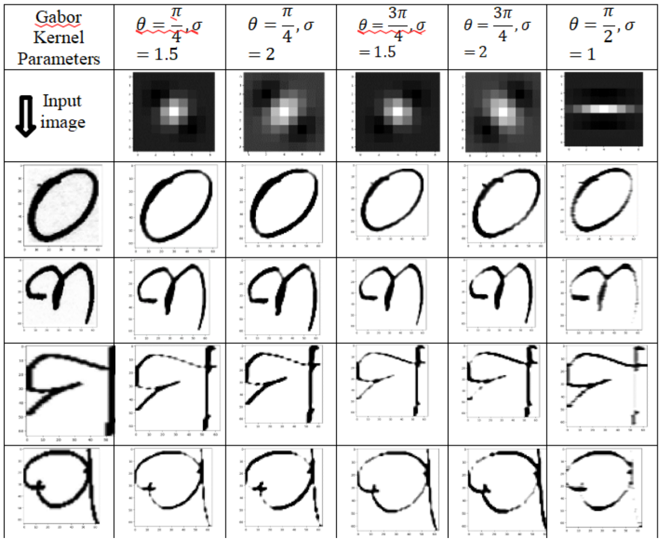
c) Classification by machine learning algorithms: Utilizing the Support Vector Machine (SVM), Random Forest (RF), XG Boost, and k-Nearest Neighbor (kNN) algorithms, the performance of the proposed OHCNR model is compared with these techniques.

i) Random Forest: Random Forest is a bunch of decision trees (DT), a supervised learning methodology that can be applied to classification problems based on the idea of ensemble learning (EL). The method of integrating various classifiers to address complex problems and improve model performance is known as EL. Random forest takes a random subset from the training dataset, and adds some duplicate instances to make the same size as the training set. This is called a bootstrapped dataset, and its working procedure is shown in Fig. 8(a). So many DT's are trained on these various subsets of the training set, and it takes the average value to make the decision. Instead of depending on a single decision tree, the random forest uses decisions from all of the trees to anticipate the outcome based on majority voting. The root of RF takes a random subset of features available and picks the one that gives the best split in data based on Gini impurity, as shown in Eq. (8), where C is the number of classes and p(i) is the probability of randomly picking an element of class i.

$$G = \sum_{i=1}^{C} p(i) + (1 - p(i)) \quad (8)$$

ii) Support Vector Machine: A supervised machine learning technique called SVM requires labelled data. The goal of the SVM algorithm is to find the best decision boundary or line that divides the data into "n" classes so that following data points can be promptly classified into the appropriate class category. This ideal decision boundary is known as the "hyperplane". Mathematically, any hyperplane can be represented as in Eq. (9), where xi is the feature value.

$$\sum_{i=1}^{k} w_i . x_i + b = 0 \quad (9)$$



Gabor Kernel Parameters
$\theta = \frac{\pi}{4}, \sigma = 1.5$
$\theta = \frac{\pi}{4}, \sigma = 2$
$\theta = \frac{3\pi}{4}, \sigma = 1.5$
$\theta = \frac{3\pi}{4}, \sigma = 2$
$\theta = \frac{\pi}{2}, \sigma = 1$

(a)

(b)

(c)

Fig. 8. (a) Working procedure of random forest. (b) Working procedure of support vector machine. (c) Working procedure of k – Nearest neighbor.

Support vectors are the data points or vectors that are closest to the hyperplane and have the biggest impact on where the hyperplane is located, as seen in Fig. 8(b).

iii) Extreme Gradient Boosting (XG Boost): Gradient boosting is the technique of "boosting" or strengthening a single weak model by combining it with a number of additional weak models to produce a more reliable model all together. The XG Boost is a gradient boosting solution that pushes the limits of processing power for boosted tree algorithms. It is scalable and incredibly accurate. It was developed mainly to improve the efficiency and performance of machine learning models. In addition to building trees, XG Boost also evaluates the quality of splits at each potential split in the training set by scanning through gradient values level-wise and using these partial sums.

iv) K-Nearest Neighbor (kNN): One of the fundamental classification algorithms, the k-nearest neighbor algorithm, is well-liked for its effectiveness and simplicity. It stores the training dataset rather than learning from it immediately, which makes it a lazy learner algorithm. The algorithm selects k, the number of the nearest data points or neighbors, then calculates the Euclidean distance of the k number of neighbors, and its working process is shown in Fig. 8(c). The most popular classes are selected and given to the test pattern in the k-NN algorithm after searching for the closest training patterns for each test pattern. Some of the method's limitations are that it stores the complete training set for testing purposes, searches the entire training set in order to categorize a certain pattern, and that classification performance suffers in the presence of noisy data.

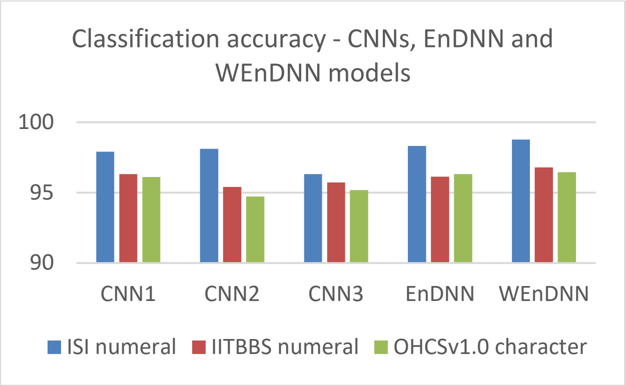
VI. Result Analysis

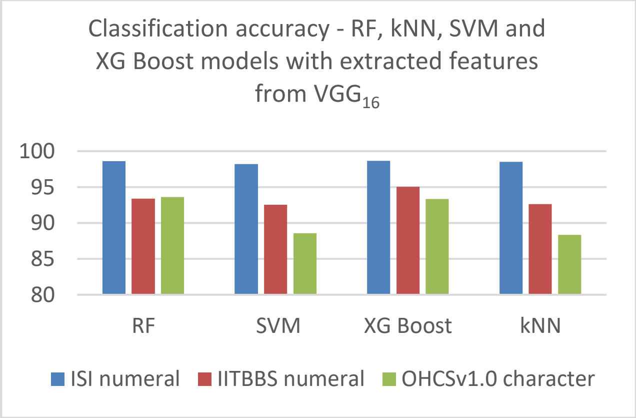
A PC with a 2.81 GHz processor and 16 GB of RAM was used to implement both the proposed character recognition model and the state-of-the-art models. The EnDNN model is implemented in Python to evaluate its recognition accuracy of handwritten characters and numerals. Training and validation accuracy are computed for the three different CNN, EnDNN, and WEnDNN models. Three standard benchmark datasets of handwritten Odia characters are used to evaluate the performance of the proposed model. Table I lists the number of samples used in training and testing for each dataset. The accuracy is calculated by using a confusion matrix and is defined as the number of correct predictions by the classifier based on the total number of predictions. For our study, in a random forest model, 50 decision trees are ensembled. The handcrafted features for our study were a combination of pixel intensity values (PV) as well as features extracted from Gabor filters (GF). The Gabor filters are applied to original images with the following parameters: Image size (x, y) = (9,9) $\sigma = 1.5,\ 2,\ 2.5$ $\theta = 45^0, 90^0, 135^0, \lambda = 0.79$, $\gamma = 0.5$ and $\psi = 0$. The classification result obtained from different experiments by these models with handcrafted and non-handcrafted feature descriptors is shown in Table III.

TABLE III. PERFORMANCE ANALYSIS OF THE PROPOSED MODEL

Approach	**Descriptor**	**Datasets**		
		ISI Image – numeral (10 classes)	**IITBBS-numeral (10 classes)**	**NITROHCS – character (47 classes)**
1. Handcrafted features with ML algorithms	Pixel value +Gabor + RF	95.80	90.34	91.93
	Pixel value + Gabor + SVM	94.81	89.52	90.62
	Pixel value +Gabor + XG Boost	94.21	91.21	90.01
	Pixel value +Gabor + kNN	92.51	88.78	89.85
2.Non-handcrafted feature with VGG16 + ML algorithms	VGG$_{16}$ + RF	98.61	93.37	93.59
	VGG$_{16}$ + SVM	98.21	92.54	88.58
	VGG$_{16}$ + XG Boost	98.67	95.03	93.35
	VGG$_{16}$ + k NN	98.50	92.63	88.36
3.Non-handcrafted feature with NN	CNN$_1$	97.92	96.31	96.11
	CNN$_2$	98.12	95.40	94.73
	CNN$_3$	96.33	95.73	95.19
4.Ensemble of Deep learning models	EnDNN	98.33	96.13	96.31
5.Weighted Ensemble of Deep learning models	WEnDNN	98.78	96.81	96.45

Table III and Fig. 9 investigate the performance of the WEnDNN model under different datasets. The proposed state-of-the-art model's performance was also compared with other approaches (1-5). The experimental results highlighted that the proposed WEnDNN model has gained maximum recognition performance for all handwritten characters as well as numeral recognition. This is because each model in the ensemble might focus on different aspects of the input data, capturing distinct patterns and characteristics of handwritten characters. Each CNN model in an ensemble learns different representations or features from the input data. Combining these diverse representations allows the ensemble to capture a broader range of patterns and variations in handwritten characters. By combining the strengths of multiple models, the ensemble can achieve a more comprehensive and discriminative representation of the handwritten characters, leading to improved classification performance in EnDNN. In case of WEnDNN, the weights assigned to CNN models can be dynamically adjusted based on their performance on validation data or during training. By continuously adjusting the weights, the WEnDNN optimizes its performance, leading to improved classification accuracy.





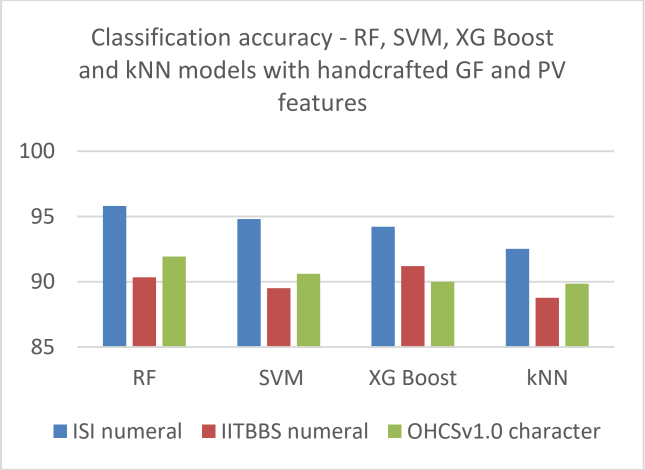


Fig. 9. Result analysis of proposed ensemble model and different ML models with hand-crafted and non-handcrafted features.

The training and validation accuracy as well as training and validation loss of CNN1, CNN2, and CNN3 for the ISI image database are shown in Fig. 11. The confusion matrix and fraction of incorrect predictions of the proposed WEnDNN for the ISI Image numeral database are shown in Fig. 12(a). Structural difference between the numerals present in Odia language is shown in Fig. 10, which leads to more misclassification results. From Fig. 12(b), it is clear that the incorrect prediction of the numeral six(୬) is more compared to other numerals, as six(୬) is predicted as nine (୯), three(୩) or seven(୭).

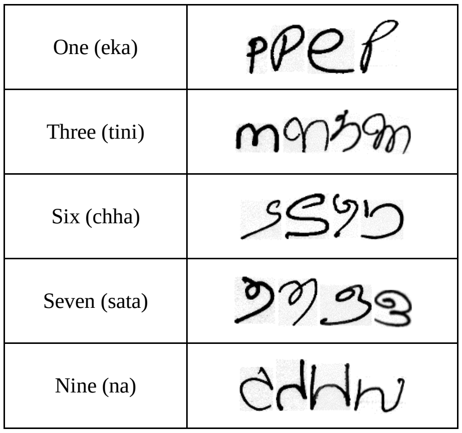

Fig. 10. Structurally different numerals in ISI Kolkata Image database.

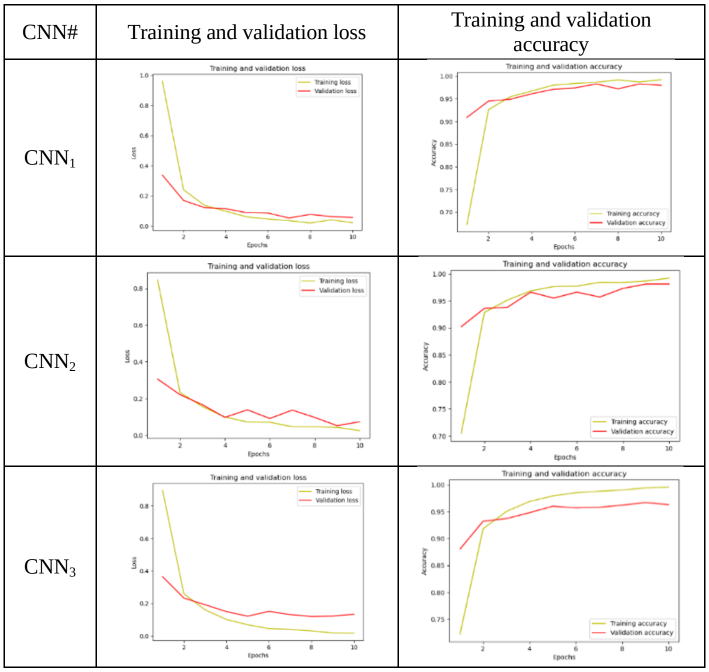

Fig. 11. The training and validation accuracy and loss at each epoch of ISI numeral database.

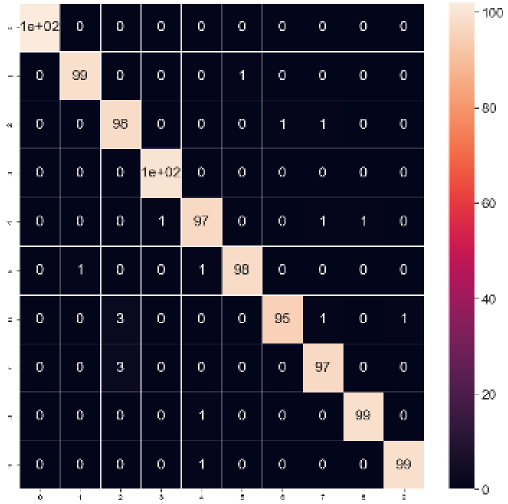
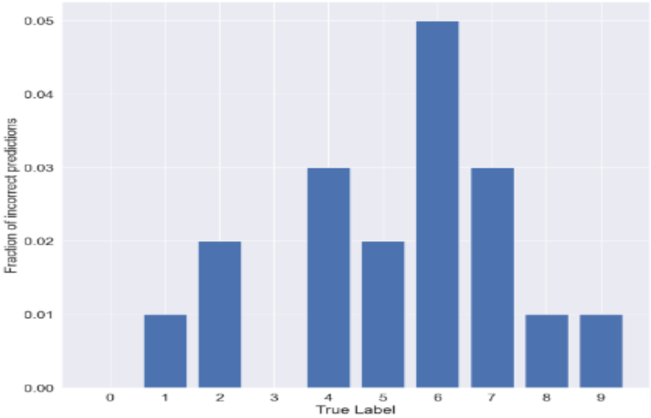


(a)



(b)

Fig. 12. (a) Confusion matrix of WEnDNN. (b) Fraction of incorrect predictions of WEnDNN.

WEnDNN can also handle the noise in a more effective way. When noise is present in the data, different models may have different levels of sensitivity to noise. By combining their predictions with appropriate weights, the ensemble can reduce the impact of noise by relying more on the predictions of models that are less affected by the noise. If a particular CNN model is more susceptible to noise and tends to produce incorrect predictions for noisy samples, its weight can be reduced. Other models that are more accurate in the presence of noise can be assigned higher weights. By giving more importance to the predictions of robust models, the ensemble can mitigate the effects of noise and make more reliable classifications.

A comparison among the performance of ensemble model applied on applications is shown in Table IV.

TABLE IV. DIFFERENT ENSEMBLE LEARNING APPLICATIONS

Reference	Application field	Method	# of classes	Accuracy
[42]	skin disease	Ensemble CART, SVM, DT, RF, GBDT	6	95.9%
[43]	skin disease	Ensemble using Bagging, AdaBoost and Gradient Boosting classifier techniques; PAC, LDA, RNC, BNB, NB, ETC	6	98.56% - Bagging 99.25% - AdaBoost 99.68% - Gradient Boosting
[44]	OCR	Ensemble of Decision Trees, Random Forest, Extra Trees Classifier, MLP, and SVM for the detection of printed regions in an invoice	-	94.53%
[31]	OCR	Ensemble of 30 deep convolutional neural network model was constructed using a stacking method	35	98.85%
[45]	Cloud image patches	Ensemble of 10 CNN’s (4 CONV	5	99.40%

		and POOL layers and 3FC layers)		
[46]	IoT Cyber Attacks	An Ensemble of Deep RNN for the detection of IoT Cyber Attacks by 6 LSTM models	2	99.41%
[47]	Cardiovascular Disease	An ensemble-based approach of machine learning and deep learning models	2	88.70%
[48]	Plant disease	An ensemble of Random Forest and K-Nearest Neighbor (KNN)	3	96.00%

VII. CONCLUSION

This study makes an effort to identify the handwritten atomic Odia character and numeral. The handwritten characters causes the biggest issue in the character recognition procedure due to the freestyle writings of the individual and varies from person to person. There are many different shapes and orientations that a letter can take. Firstly, CNN models are designed from scratch, then a learning-based weighted average ensemble of deep neural network models (WEnDNN) is proposed to classify 10 digits and 47 characters present in alphabet set of Odia language and to enhance the accuracy. The performance of proposed WEnDNN model with EnDNN and machine learning models, namely, like RF, SVM, k NN and XG Boost trained on hand-crafted extracted features by using Gabor filter and pixel intensity values, non-handcrafted extracted features from pre-trained VGG16 neural network are compared. The proposed WEnDNN OHCNR model's overall accuracy recorded as 98.78% on ISI image numeral database. In comparison to state-of-the-art techniques, it has been found that the suggested method offers superior recognition accuracy. These ensemble models can be extended to continuously learn and adapt to changing data patterns over time. This could involve online learning approaches where the ensemble is updated incrementally as new data becomes available, allowing it to stay relevant and effective in dynamic environments.

Monitoring Student Attendance Through Vision Transformer-based Iris Recognition

Slimane Ennajar, Walid Bouarifi
Mathematical Team and Information Processing-National School of Applied Sciences, SAFI Cadi AYYAD University
Marrakech, Morocco

***Abstract*—In the context of the ongoing digital transformation, the effective monitoring of student attendance holds paramount significance for educational establishments. This study presents an innovative approach using Vision Transformer technology for iris recognition to automate student attendance tracking. We fine-tuned Vision Transformer models, specifically ViT-B16, ViT-B32, ViT-L16, and ViT-L32, using the CASIA-Iris-Syn dataset and focused on overcoming challenges related to intra-class variation through data augmentation techniques, including rotation, shearing, and brightness adjustments. The results reveal that ViT-L16 is the most proficient, achieving an impressive accuracy of 95.69%. Comparative analysis with prior methodologies, specifically those employing Vision Transformer with Convolutional Neural Network, underscores the superiority of our proposed ViT-L16 model. This superiority is evident across various metrics, including accuracy, precision, recall, and F1 score. The experimental setup involves the use of Jupyter Notebook, Python technologies, TensorFlow, and Keras, emphasizing evaluations based on loss, accuracy, and Confusion Matrix. ViT-L16 consistently outshines other models, showcasing its resilience in iris recognition for student attendance. This research marks a significant step towards modernizing attendance systems, offering an accurate and automated solution suitable for the evolving needs of educational settings. Future work could explore integrating additional biometric modalities and refining Vision Transformer architecture for enhanced performance and broader application in educational environments.**

Keywords*—Iris Recognition; Vision transformer; student attendance; vision transformer models; educational technology

I. Introduction

A Student Attendance System is a digital solution designed to track and manage the attendance of students in educational institutions. It offers an efficient and accurate way to record and monitor student attendance, replacing traditional manual methods. Additionally, applying Student Attendance System significantly enhance the organization, precision, and transparency within educational institutions. It can also serve as a tool for analyzing attendance patterns, identifying areas for improvement, and fostering communication between educators and parents.

Accurate and timely attendance records are fundamental for identifying student absenteeism, serving as a crucial component in promoting student retention and academic achievement [1]. By meticulously tracking attendance, educators can readily implement necessary interventions for at-risk students, facilitating their academic success.

Many educational institutions still employ manual student attendance tracking, such as roll call or sign-in sheets. These methods are inefficient, as they are time-consuming and susceptible to human error. Additionally, they lack real-time capabilities, hindering the timely identification and resolution of attendance issues. Furthermore, manual methods offer limited security and privacy compared to biometric solutions. Vision Transformer (ViT) technology seeks to address these shortcomings by automating attendance, potentially reducing educator workload [2]. ViTs leverage iris recognition, a biometric approach offering greater accuracy, security, and real-time monitoring than manual methods. This transformation can streamline administrative processes and align with the ongoing integration of technology within the educational sector.

Traditional attendance tracking solutions often rely on manual methods (roll calls, sign-in sheets), card-based systems (RFID [3][4]), or biometric technologies [5][6]. While these methods offer varying degrees of utility, they frequently encounter limitations in efficiency, security, and accuracy. The ViT-based approach demonstrates a technological evolution in attendance management, leveraging sophisticated image processing and machine learning for iris recognition. This translates to superior security and precision, minimizing the potential for fraudulent activity. Furthermore, process automation makes the ViT approach a uniquely efficient and dependable solution within educational and organizational settings.Haut du formulaire.

Iris recognition technology is being integrated into student attendance systems to automate and enhance monitoring and documentation processes. This biometric approach involves capturing and analyzing the unique patterns within the iris (the colored ring surrounding the pupil) [7]. Extracted features, including crypts, furrows, and freckles, serve as the basis for generating unique biometric templates for each individual.

Integrating AI, especially Vision Transformer technology, demonstrates a commitment to technological advancement within the educational institution. It positions the institution at the forefront of leveraging innovative solutions for routine tasks.

Addressing this challenge, we propose an innovative method for handling student attendance in educational institutions through the application of Computer Vision. Our strategy involves the detection and recognition of students' irises in classrooms utilizing a VIT. The primary focus of this paper is the creation of a transformer model designed specifically for the identification and recognition of iris images.

The specific tasks were carried out according to the following steps:

- Fine-tuning various Vision Transformer models to evaluate their performance in iris image classification.
- Utilizing a dataset from CASIA-Iris-Syn to assess the effectiveness of the proposed method.
- Evaluating the performance and accuracy of different Vision Transformer models, including ViT-B16, ViT-B32, ViT-L16, and ViT-L32, for the identification and classification of iris images.
- The results achieved demonstrated high performance, with an accuracy rate of 95.69% for iris image classification.

The subsequent sections of this paper are organized as follows: Section 2 offers a review of the existing studies correlated to iris image recognition in attendance systems and investigates ViT applications in image processing. Section 3 outlines the materials and methods utilized in the experimental approach. Moving forward to Section 4, the paper examines the results obtained and conducts a performance evaluation. Section 5 provides a comparative analysis of the proposed models. Lastly, Section 6 encapsulates the conclusions derived from this study.

II. Related Work

Various studies have explored different methods for monitoring attendance, Okokpujie et al. [8] implemented a Student Attendance System that utilizes Iris Biometric Recognition. The experimental findings indicate that the system operates through a web-based platform. Student identification is achieved by comparing the acquired iris image with the database entries. The system assigns an integer value of (1) for a successful match and (0) for no match, with these outcomes are then stored in a MySQL-created database.

Shaban et al. [9] proposed a multimodal system utilizing ear and iris biometrics at the feature fusion stage to recognize students in electronic examinations (E-exams) amid the COVID-19 pandemic. The approach attained a precision rate of 92.6%.

Hassan et al. [10] devised a technique for iris segmentation comprising two stages. Initially, it identifies the outer iris boundary, followed by the detection of the inner iris boundary in the second stage. The method underwent testing on CASIA iris image datasets V1 and V4, yielding accuracy results of 100% and 99.16% respectively.

Trabelsi & Shuaib, [11] proposed a biometric attendance system using fingerprint and iris recognition to improve accuracy and security in educational settings. This system addresses limitations of manual methods by offering reliable and efficient student identification, enhancing overall attendance recording processes. Similarly, Adamu, [12] introduced an advanced system integrating fingerprint and iris biometrics for attendance management in higher education. This system replaces traditional methods with a secure, efficient, and accurate approach. Utilizing fingerprint and iris scanners at lecture entrances, it verifies student identities against stored biometric data, enabling real-time tracking and reporting.

Kadry & Smaili, [13] implemented a wireless attendance management system incorporating Daugman's algorithm (Daugman, 2003) for iris recognition. This biometrics-based system, integrated with wireless technology, addresses issues related to inaccurate attendance records and surpasses the challenges associated with establishing a dedicated network for this purpose.

Khatun et al. [14] introduced the Iris Recognition Attendance Management System, which employs a camera to capture real-time images of the human iris, and storing this data in a database. The system utilizes the Gray-coding algorithm in MATLAB data analysis software to compute the iris radius. Employing MATLAB, it compares the radius of each individual with the previously stored value and automatically sends the attendance report to a predefined email address, eliminating the need for human intervention.

Sujatha et al. [15] proposed a solution for a biometric-based attendance system utilizing iris recognition, interfaced with NI MYRIO. The proposal emphasizes the robustness of iris recognition, highlighting its reliability, accuracy, and efficiency attributed to the unique and immutable characteristics of the iris. Furthermore, NI LABVIEW, a graphical user interface-based software, facilitates real-time monitoring and attendance management. The integration of features such as SMS notifications for absentees and the generation of Excel sheets enhances the overall functionality of the system.

Joshy & Jalaja. [16] introduced a biometric authentication system based on the Internet of Things (IoT), and emphasizes the use of iris recognition for its unparalleled accuracy and security. The proposed system incorporates a hybrid encryption algorithm (Blowfish and RSA) for securing data transmitted over the Internet and implements a two-step authentication process. Developed as an embedded system for secure employee authentication.

Lad & More, [17] developed a student attendance system leveraging iris detection technology, which is acknowledged as the most reliable and accurate form of biometric identification. This initiative aims to address the shortcomings of commercial systems by offering an open-source alternative. The system employs the Hough transform for automatic iris segmentation, normalizes the iris region, and uses 1D Log-Gabor filters for feature extraction. These steps are designed to enhance the efficiency and accuracy of attendance tracking in educational contexts.

In [18], the authors presented a multimodal biometric system utilizing Convolutional Neural Networks (CNN) and transfer learning for iris recognition. It aims to overcome limitations in unimodal biometric methods by focusing on deep learning models for analyzing both left and right irises. Employing back-propagation with Adam's optimization, the system demonstrates high accuracy on public datasets, IITD and CASIA-Iris-V3 Interval, achieving up to 99% accuracy. This study underscores the effectiveness of combining CNN characteristics and transfer learning in real-time iris recognition, enhancing security and identification processes in various conditions.

In recent studies, the Vision Transformer has been employed for image classification and identification, representing a neural network architecture tailored specifically for image processing in computer vision applications [19].The ViT is a neural network crafted for image processing in computer vision. It employs a self-attention mechanism commonly found in natural language processing, setting it apart from traditional image processing architectures like CNNs and RNNs. Introduced to address limitations in handling image data, ViT offers robust image feature representation and requires fewer computational resources for training compared to CNNs [20].

Elpina & Kusuma,[21] introduced a Swin Transformer model for feature extraction in food image classification, incorporating an SVM classifier. The methodology underwent training and evaluation utilizing the Food-101 Dataset, resulting in an impressive accuracy (ACC) of 97.61%.

Mehta et al.[22] introduced a method for ear recognition that exercises the ViT network architecture, attaining a recognition accuracy surpassing 99.36%.

Latif et al.[23] introduced a hybrid model combining ViT and Convolutional Neural Network (CNN) for the identification and verification of iris images. The hybrid model demonstrated an accuracy of up to 93.66% in recognizing iris patterns.

Ha et al.[24] employed the Vision Transformer architecture to extract data features and categorize X-ray images as either pneumonia-positive or negative. Experimental findings reveal that the Vision Transformer algorithm consistently yields favorable classification outcomes, achieving an accuracy of approximately 94%.

III. Materials and Methods

A. Proposed Methodologies

This paper investigates the enhancement of student attendance management through a novel ViT-based iris recognition approach. This approach leverages automation to improve the accuracy and efficiency of attendance tracking.

Fig. 1 illustrates our proposed Vision Transformers approach for iris identification and recognition.

B. Dataset

Our study utilized a dataset sourced from CASIA-Iris-Syn, featuring 8533 artificially generated iris images distributed across 50 classes, as illustrated in Fig. 2. The textures of these iris images were automatically synthesized from a subset of CASIA-IrisV1.Subsequently, the iris ring regions were incorporated into authentic iris images, augmenting the realism of the artificial iris images. Intra-class variations, including deformation, blurring, and rotation, were introduced into the synthesized iris dataset. The training dataset comprises 5814 iris images in JPG format. The validation and test sets were assessed using new databases, consisting of 1027 images and 1692 images, respectively. A graphical illustration of the configuration of this dataset as depicted in Fig. 3.

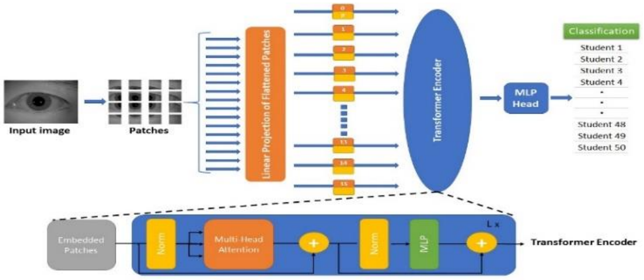

Fig. 1. Visualization of our proposed Vision Transformer (ViT) model for identifying and recognizing iris images. Initially, the input image undergoes segmentation into fixed-size patches, which are subsequently flattened. Following this, position embeddings are introduced, and the resulting sequence of vectors is then passed through a standard Transformer encoder. The inspiration for this illustration is derived from [2].

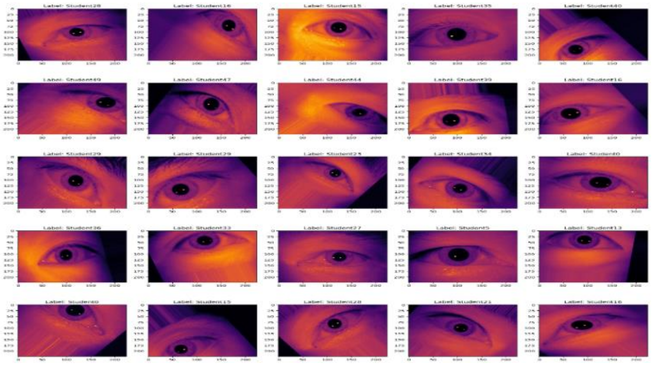

Fig. 2. Example of iris images in the Iris Dataset (50 classes).

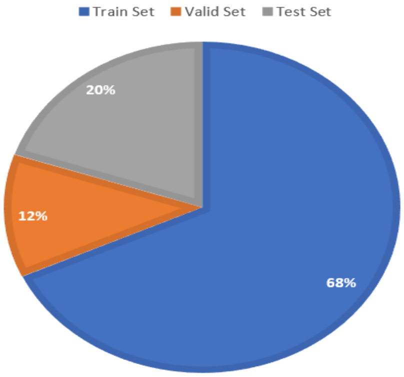

Fig. 3. Distribution of the Iris dataset (50 classes).

C. Data Augmentation Technique

Data augmentation serves as a pivotal technique in machine learning, aimed at artificially expanding the scale of a training dataset through the application of diverse transformations to the existing data. This strategy proves instrumental in enhancing the generalization and resilience of machine learning models. Its significance becomes more pronounced when dealing with a restricted training dataset size. By creating novel variations to pre-existing data, data augmentation serves a dual purpose of mitigating overfitting risks and enabling the model to capture more resilient features. Widely utilized across domains like image classification, object detection, and segmentation, data augmentation emerges as a fundamental tool for bolstering the performance and adaptability of machine learning models.

In this research, our emphasis was directed towards various data augmentation methods. The precise parameters selected for each operation are detailed in Table I.

The Table I outlines the specific parameters employed for various data augmentation operations. Rotation is set at 30 degrees, shearing at 0.2 radians, and zooming within a range of 0.2. Horizontal and vertical flips are enabled, and brightness is varied within the range of 0.4 to 1.5. These meticulously chosen parameters contribute to the augmentation of the training dataset, and ultimately bolstering the model's robustness and performance.

TABLE I. DATA AUGMENTATION PARAMETERS

Operations	Values
Rotation	30 degrees
Shearing	0.2 radians
Zooming (range)	0.2
Horizontal flip	True
Vertical flip	True
Brightness	[0.4, 1.5]

D. Vision Transformer (ViT)

The Vision Transformer presents a revolutionary deep learning architecture designed to tackle computer vision tasks, challenging the conventional prominence of convolutional neural networks. Originating from the paper titled "An Image is Worth 16x16 Words: Transformers for Image Recognition" by Alexey Dosovitskiy et al.[2], ViT extends the transformer architecture, initially crafted for natural language processing, into the realm of images. This adaptation involves the incorporation of self-attention mechanisms, enabling the model to adeptly capture long-range dependencies within the input data. ViT's introduction marks a paradigm shift, opening up new possibilities for image recognition and paving the way for diverse applications beyond the confines of traditional CNN-based approaches.

In contrast to processing the entire image in a holistic manner, the Vision Transformer adopts a strategy of partitioning the input image into fixed-size, non-overlapping patches. Subsequently, each of these patches undergoes a linear embedding, transforming it into a flat vector and composing the input sequence for the transformer. To preserve spatial information, positional embeddings are introduced to the patch embeddings. This addition enables the model to discern the spatial relationships existing between distinct patches, ensuring a nuanced understanding of the overall image structure. The incorporation of such mechanisms enhances ViT's capacity to effectively process and interpret intricate spatial features within images.

ViT models are typically pre-trained on large datasets, such as ImageNet, using a contrastive learning framework. This pre-training helps the model learn rich visual representations. The pre-trained ViT model is fine-tuned for specific tasks by adding a linear classification head on top. The model can be fine-tuned for various computer vision tasks such as image classification, object detection, and segmentation.

ViT has shown good scalability, performing well on both small and large datasets. This scalability is advantageous for adapting the model to different tasks.

In this research, the Vision Transformer architecture is crafted with adjustable dimensions to suit specific requirements. Additionally, each parameter in the vision transformer holds a crucial role, and their descriptions are outlined as follows:

- image_size=224: This parameter defines the preferred dimensions (width and height) of the input images for the model. In this instance, the images are expected to have dimensions of 224x224 pixels.
- patch_size=16: The images undergo segmentation into smaller patches, and this parameter determines the size (width and height) of each patch. In this case, each patch measures 16x16 pixels.
- num_classes=50: This parameter signifies the number of classes involved in the classification task. In this particular example, the model is configured to categorize inputs into 50 classes.
- dropout=0.2: This parameter governs the dropout rate, a regularization technique employed to mitigate overfitting. It involves randomly setting a fraction of input units to 0 during training.

E. Evaluation Metrics

The assessment of prediction algorithms in this study relies on various performance metrics. The paper examines the subsequent evaluation metrics to gauge the efficacy of the proposed model:

1) Accuracy score: The accuracy score is a performance metric used to measure the overall correctness of a predictive model. It is calculated by dividing the number of correct predictions by the total number of predictions and is often expressed as a percentage[25]. The formula for accuracy is shown in equation (1).

$$\text{Accuracy} = (\text{TP} + \text{TN})/(\text{TP} + \text{TN} + \text{FP} + \text{FN}) \quad (1)$$

2) Precision: Precision is a performance metric used in classification tasks to assess the accuracy of the positive predictions made by a model. It is defined as the ratio of true positive predictions to the total number of positive predictions (both true positives and false positives) [25].The formula for precision is shown in equation (2).

$$\text{Precision} = (\text{TP})/(\text{TP} + \text{FP}) \quad (2)$$

3) Recall: Recall, also known as sensitivity or true positive rate, is a performance metric used in classification tasks to evaluate a model's ability to correctly identify all relevant instances of a particular class. It is the ratio of true positive predictions to the total number of actual positive instances (including both true positives and false negatives) [25].The formula for recall is shown in equation (3):

$$\mathrm{Recall} = (\mathrm{TP})/(\mathrm{TP} + \mathrm{FN}) \qquad (3)$$

4) F1-score: The F1 score is a metric commonly used in classification tasks that combines both precision and recall into a single measure. It is particularly useful when there is an uneven class distribution (imbalanced datasets) and provides a balance between the precision and recall metrics [25].The formula for the F1 score is shown in equation (4):

$$\mathrm{F1} = 2 * (\mathrm{precision} + \mathrm{recall})/(\mathrm{precision} + \mathrm{recall}) \qquad (4)$$

5) Matthews correlation coefficient: The Matthews correlation coefficient (MCC) is a metric used to evaluate the performance of binary classification models, particularly when dealing with imbalanced datasets. It takes into account true positives, true negatives, false positives, and false negatives. The formula for Matthews correlation coefficient is shown in equation (5):

$$\mathrm{MCC} = \frac{\mathrm{TP}\times\mathrm{TN}-\mathrm{FP}\times\mathrm{FN}}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}} \times 100 \qquad (5)$$

IV. Results and Discussions

The primary objective of this research is to develop a transformer model designed for the identification and recognition of iris images. The model underwent training using both regular and augmented images, with where data augmentation employed to enhance the training dataset. Training involved 5814 images, validation with 1027 images, and testing utilized 1692 images. The network layers were subsequently frozen and fine-tuned with dense layers containing 1024, 512, 256, and 50 neurons, respectively.

Table II summarizes the performance metrics of different ViT models, each trained for 50 epochs, in the context of iris image identification and recognition. Notably, the ViT-L16 model emerges as the top performer with an accuracy score of 95.69%, demonstrating its effectiveness in accurately classifying iris images. ViT-L32, ViT-B32, and ViT-B16 also exhibit commendable performance, achieving accuracy scores of 94.03%, 93.26%, and 92.02% respectively. In terms of precision, recall, F1 score, and Matthews Correlation Coefficient (MCC), ViT-L16 consistently outperforms the other models, emphasizing its robustness in various evaluation criteria. These results indicate that the ViT-L16 model, with its customizable dimensions and advanced architecture, proves to be particularly effective in iris recognition tasks, demonstrating its potential for applications such as student attendance using Vision Transformer technology.

A. Experimental Setup

The experimental setup utilized Jupyter Notebook along with Python technologies such as NumPy, Pandas, and OpenCV for image processing tasks. For implementing classifiers, Scikit-Learn, Anaconda, and Python 3.9 were employed. The Vision Transformer model underwent training and testing processes using TensorFlow and Keras, leveraging Google Colab PRO T4-GPU with reported memory at 51GB and storage space at 166.77GB for refined computational capabilities.

TABLE II. Accuracy Score, Precision Score, Recall Score, F1 Score and MCC of our Vision Transformers Models

Model	Number of epochs	Accuracy Score (%)	Precision Score (%)	Recall Score (%)	F1Score (%)	MCC (%)
ViT-B16	50	92.02	93.83	92.02	91.85	91.91
ViT-B32	50	93.26	93.87	93.26	9327	93.14
ViT-L16	50	95.69	96.08	95.69	95.64	95.61
ViT-L32	50	94.03	94.65	94.03	93.88	93.93

B. Loss and Accuracy

1) Loss: serves as an indicator of the model's performance on training data, gauging the discrepancy between predicted values and actual ground truth. The training objective involves minimizing the loss, with a lower value indicating closer alignment between model predictions and actual values.

2) Accuracy: serves as a metric for the overall correctness of the model, determining the ratio of correctly predicted instances to the total instances. The goal in both training and testing phases is to maximize accuracy, as a higher value signifies a greater proportion of correct predictions.

In Fig. 4, the evaluation of loss and accuracy is depicted for the ViT-B16, ViT-B32, ViT-L16, and ViT-L32 models. The results clearly indicate that the ViT-L16 model exhibits superior performance, confirming its heightened effectiveness when compared to the other models.

C. Confusion Matrix

An additional evaluation metric, the Confusion Matrix, was utilized to assess the overall effectiveness of a classification model. The Confusion Matrix serves as a tabular summary, offering a detailed breakdown of the model's predictions in comparison to the actual class labels. The evaluation outcomes for the mentioned algorithms, using these criteria, are illustrated in Fig. 5.

Fig. 5. Confusion Matrix of ViT-B16 (a), ViT-B32 (b), ViT-L16 (c), and ViT-L32 (d).

Fig. 5(a) presented the recognition outcomes achieved using the ViT-B16 model. The average count of accurate recognitions for each category was 31.16. The expected correct recognition count ranged between 33 and 34. As a result, the average accuracy attained by the ViT-B16 model was 92.02%.

In Fig. 5(b), the ViT-B32 model's recognition results were presented. The mean correct recognition count for each category was 31.56, with the expected correct recognition count ranging 33 and 34. As a result, the average accuracy of the ViT-B32 model was 93.26%.

Moving to Fig. 5(c), it demonstrated the recognition outcomes of the ViT-L16 model. The mean correct recognition number for each category was 32.44, with the expected correct recognition number ranging between 33 and 34. The ViT-L16 model achieved an average accuracy of 95.69%.

In Fig. 5(d), the recognition results of the ViT-L32 model were depicted. The mean correct recognition number for each category was 31.82, and the expected correct recognition number ranged between 30 and 34. The average accuracy of the ViT-L32 model was 94.03%.

D. Classification Report

Fig. 6(a) displays the classification report for the ViT-B16 model, indicating precision values for iris classes ranging from 0.47 to 1. Additionally, the recall performance values for iris classes fall within the range of 0.35 to 1, with corresponding support values between 33 and 34. F1 scores for the iris classes vary from 0.52 to 1. The ViT-B16 model achieves an accuracy of 0.92 (92%) based on the F1 score, considering 1692 support values. The macro and weighted averages for precision and recall are 0.94, 0.92, 0.94, and 0.92, and the f1 scores are 0.92 and 0.92, each with support values of 1692.

Fig. 6(b) exhibits the classification report of the ViT-B32 model, revealing precision values within the range of 0.73 to 1 for iris classes. The recall performance spans from 0.65 to 1 across iris classes, accompanied by corresponding support values ranging from 33 to 34. F1 scores for the iris classes vary from 0.73 to 1. The ViT-B32 model attains an accuracy of 0.93 (93%) based on the F1 score, taking into account 1692 support values. The macro and weighted averages for precision and recall stand at 0.94, 0.93, 0.94, and 0.93, with f1 scores of 0.93 and 0.93, respectively, supported by 1692 instances.

Fig. 6(c) illustrates the ViT-L16 model's classification report, delineating precision values for iris classes ranging from 0.84 to 1. Likewise, the recall performance for iris classes spans from 0.53 to 1, accompanied by support values ranging between 33 and 34. F1 scores for the iris classes vary between 0.69 and 1. The accuracy of the ViT-B16 model stands at 0.96 (96%) based on the F1 score, considering 1692 support values. The macro and weighted averages for precision and recall are 0.96, 0.96, 0.96, and 0.96, respectively, with f1 scores of 0.96 and 0.96, supported by 1692 instances.

In Fig. 6(d), the classification report of the ViT-L32 model illustrates precision values for iris classes spanning from 0.57 to 1. Moreover, recall performance values for iris classes range from 0.32 to 1, with corresponding support values falling between 33 and 34. F1 scores for the iris classes are distributed within the range of 0.46 to 1. The ViT-B16 model attains an accuracy of 0.94 (94%) based on the F1 score, taking into account 1692 support values. The precision and recall values for both macro and weighted averages are 0.95, 0.94, 0.95, and 0.94, with F1 scores of 0.94 and 0.94, respectively, supported by 1692 instances.

(d)

Fig. 6. Classification report of ViT-B16 (a), ViT-B32 (b), ViT-L16 (c), and ViT-L32 (d).

The research team faced challenges during the fine-tuning process due to intra-class variations within the synthesized iris dataset. To address these limitations, data augmentation techniques such as deformation, blurring, and rotation were employed. These augmentations significantly enhanced the robustness of the Vision Transformer models, particularly the ViT-L16, by introducing artificial variations within the training data. This resulted in improved model performance on real-world iris patterns with diverse characteristics, leading to higher accuracy and reliability in iris recognition tasks. These findings demonstrate the effectiveness of data augmentation in mitigating the effects of intra-class variations and highlight the adaptability of Vision Transformer architectures for tasks like student attendance monitoring using iris recognition.

This research explored the implementation of various Vision Transformer models (ViT-B16, ViT-B32, ViT-L16, and ViT-L32) for iris-based student attendance tracking. The ViT-L16 model demonstrated the highest performance in terms of accuracy, precision, and recall. Additionally, the study confirmed the adaptability of Vision Transformer architectures for iris recognition, underscoring the importance of data augmentation in improving model robustness.

V. Comparative Analysis

Table III presents a comparative examination of outcomes derived from our approach, employing Vision Transformer models ViT-L16 and ViT-L32, juxtaposed with findings from a preceding investigation utilizing ViT with CNN. The assessment hinges on pivotal metrics, including accuracy, precision, recall, and F1 score, observed across a span of 50 epochs.

In the study delineated by [23], the ViT+CNN model attained an accuracy of 93.66% after 50 epochs, although explicit figures for precision, recall, and F1 score remain undisclosed. Our methodology, leveraging ViT-L16, outperformed these results, manifesting an elevated accuracy of 95.69%. Furthermore, precision, recall, and F1 score for ViT-L16 registered at 96.08%, 95.69%, and 95.64%, sequentially. This signifies an amelioration in our model's capacity to accurately discern and categorize instances.

The ViT-L16 model's exceptional performance likely stems from its architecture, which excels at processing global image features – a vital aspect of accurate iris recognition. Unlike hybrid ViT+CNN models, which may introduce redundancies or inefficiencies through convolutional layers, the ViT-L16 relies exclusively on self-attention mechanisms. This enables a more direct and focused learning process that emphasizes the most pertinent features without the limitations inherent in convolutional operations.

Comparative results across the ViT-L16, ViT-L32, and ViT+CNN models demonstrate a clear pattern: the pure transformer-based models (ViT-L16, ViT-L32) consistently outperform the hybrid ViT+CNN model in accuracy, precision, recall, and F1 score. This finding suggests that self-attention mechanisms within transformers may be intrinsically better suited for iris recognition in attendance systems compared to a hybrid approach. Furthermore, these results highlight the potential of pure transformer models for driving improvements in biometric recognition systems.

TABLE III. Comparison of Results with Previous Works

Authors	[23]	**Our method**	
Model	ViT+CNN	**ViT-L16**	ViT-L32
Epochs	50	50	50
Accuracy (%)	93.66	**95.69**	94.03
Precision (%)	--	96.08	94.65
Recall (%)	--	95.69	95.64
F1 score (%)	--	94.03	93.88

VI. Conclusions

In this research, we formulated diverse models utilizing Vision Transformers, including ViT-B16, ViT-B32, ViT-L16, and ViT-L32, to manage student attendance in educational institutions. The most effective model turned out to be ViT-L16. ViT-L16 underwent fine-tuning to perform identification and recognition of students' iris images, leveraging a dataset comprising 8533 iris images.

Furthermore, this research has formulated four models using the Vision Transformer methodology. An evaluation of all the models revealed that, although ViT-B16, ViT-B32, and ViT-L32 performed satisfactorily, the ViT-L16 transformer outshone all the models in terms of accuracy. A comparison of F1 score, precision, and recall provides supporting evidence that the ViT-L16 transformer surpasses all other models. Additionally, when compared with all the models, the ViT-L16 transformer required less training time with an equal number of epochs.

The Vision Transformer model demonstrated the effectiveness of ViT-L16 in identifying and recognizing students' iris patterns. The proposed method represents a notable contribution to advancing the development of a student attendance system capable of recording and monitoring attendance through iris images.

Our experiments manifested the inherent adaptability of Vision Transformer architectures to iris recognition tasks. ViT models displayed robust feature extraction capabilities, allowing for accurate and reliable identification of unique iris patterns. The incorporation of data augmentation techniques, including deformation, blurring, and rotation, played a crucial role in enhancing the robustness of the models. This approach effectively mitigated the effects of intra-class variations within the synthesized iris dataset.

Future research avenues could explore the integration of additional biometric modalities to enhance the overall security and accuracy of attendance systems. Additionally, the refinement of the Vision Transformer architecture, specifically tailored to the unique requirements of educational settings, holds potential for advancing the continuous improvement of biometric-based attendance solutions.

***Abstract*—This paper discusses the critical relevance of precise forecasting in liver disease, as well as the need for early identification and categorization for immediate action and personalized treatment strategies. The paper describes a unique strategy for improving liver disease classification using ultrasound image processing. The recommended technique combines the properties of the Extreme Learning Machine (ELM), Convolutional Neural Network (CNN), along Grey Wolf Optimisation (GWO) to form an integrated model known as CNN-ELM-GWO. The data is provided by Pakistan's Multan Institute of Nuclear Medicine and Radiotherapy, and it is then pre-processed utilizing bilateral and optimal wavelet filtering techniques to increase the dataset's quality. To properly extract significant visual information, feature extraction employs a deep CNN architecture using six convolutional layers, batch normalization, and max-pooling. The ELM serves as a classifier, whereas the CNN is a feature extractor. The GWO algorithm, based on grey wolf searching strategies, refines the CNN and ELM hyperparameters in two stages, progressively boosting the system's classification accuracy. When implemented in Python, CNN-ELM-GWO exceeds traditional machine learning algorithms (MLP, RF, KNN, and NB) in terms of accuracy, precision, recall, and F1-score metrics. The proposed technique achieves an impressive 99.7% accuracy, revealing its potential to significantly enhance the classification of liver disease by employing ultrasound images. The CNN-ELM-GWO technique outperforms conventional approaches in liver disease forecasting by a substantial margin of 27.5%, showing its potential to revolutionize medical imaging and prospects.**

Keywords*—Liver disease prognosis; convolutional neural network extreme learning machine; grey wolf optimization; patient care

I. Introduction

The liver, which is the most significant internal organ in the human body, is essential to many physiological functions. It is situated under the diaphragm in the upper-right region of the abdomen. The liver possesses a special capacity for regeneration and carries out a variety of essential tasks that maintain the body healthy [1]. It has a role in digestion, detoxification, metabolism, and the control of several biochemical procedures. The major functioning cells of the liver are called hepatocytes, and they are responsible for the organ's extensive blood supply [2]. Numerous vital processes that the liver performs are necessary to preserve homeostasis. It handles nutrition from the food people eat, which is one of its main metabolic functions. When glucose is required, the liver releases glucose from storage and manages its production of glycogen for energy. It produces albumin, which aids in maintaining blood pressure and volume, and blood-clotting components [3]. It also processes down lipids into energy or accumulates them as triglycerides through metabolism. In addition, the liver breaks down medications, detoxifies hazardous compounds, and changes ammonia into urea, which the kidneys may then eliminate. Additionally, it is essential to digestion because it produces bile, which facilitates the dissolution of lipids [4].

Hepatitis, Cirrhosis, and non-alcoholic fatty liver disease are among the most common illnesses classified under the category of liver diseases. Hepatitis, which often comes on by viral infections (such as Hepatitis A, B, or C), damages and inflames the liver [5]. The primary feature of cirrhosis is the damage of the liver cells, which is often caused by viral hepatitis, chronic drinking, or other conditions. As the designation implies, non-alcoholic fatty liver disease is characterized by the build-up of fat in liver cells and has the potential for progression [6]. Chronic liver illnesses can lead to the development of liver cancer, particularly hepatocellular carcinoma. Numerous symptoms, such as weariness, jaundice (a yellowing of the skin and eyes), stomach discomfort, black urine, and unexplained weight loss, might be indicative of liver disease. If these medical conditions are not addressed, they might deteriorate and have a significant impact on general health [7]. For instance, cirrhosis can result in liver failure and its complications, which include hepatic encephalopathy and bleeding from oesophageal varices [8]. Liver fibrosis and an increased probability of liver cancer are two outcomes of hepatitis. It's essential to have an early diagnosis and treatment for these illnesses in order to prevent them from becoming fatal. Establishing a healthy routine with a balanced diet, using alcohol in moderation, and receiving a hepatitis virus vaccination are preventive strategies for liver illnesses [9].

In contemporary medicine, the ability to detect liver disorders early and accurately is critical. Liver diseases are a broad category of illnesses [10]. The quality of life and consequences for patients can be significantly improved by immediate treatment and diagnosis. Furthermore, because liver illnesses have a significant negative impact on society and healthcare systems, early detection is a practical and life-saving approach [11]. The application of several cutting-edge technology and data analysis techniques is necessary for predicting liver disorders. In this field of study, machine learning and artificial intelligence approaches have become more popular [12]. A growing number of academics and medical professionals are analysing clinical and patient information utilizing machine learning methods, such as support vector machines, logistic regression, and artificial neural networks, to produce accurate predictions [13]. To determine the probability of liver diseases, these models take into consideration a variety of factors, such as previous medical information, outcomes of blood tests, imaging information, and more. There are significant clinical consequences for accurate liver disease prediction. It makes it possible to create individualized treatment programs and for early intervention [14]. For instance, individuals that are particularly susceptible to liver disease may benefit from attentive observation, lifestyle counselling, and hepatitis virus immunization recommendations. In situations of end-stage liver diseases, early identification can also help ensure a timely liver transplant. Predictive models lessen the overall load on healthcare systems by helping recognize at-risk patients and allocating healthcare resources optimally [15]. By utilizing predictive analytics, healthcare professionals may proactively address the international problem of liver disease.

Current liver disease prediction approaches are unable to fully capitalize on the promise of cutting-edge technology like deep learning and metaheuristic optimization since they frequently rely on conventional machine learning techniques. Conversely, the paper Liver Disease Prediction utilizing Convolutional Extreme Learning Machine offers a novel strategy that gets over the drawbacks of traditional techniques. The research leverages the capabilities of deep learning and non-adjustable hidden nodes by utilizing a hybrid model that includes an ELM for rapid categorization and a CNN for feature extraction. This integration takes advantage of ELM's faster learning rate while also improving prediction accuracy. In addition, by fine-tuning the hyperparameters with GWO, the models become more appropriate for the particular position.

The key contributions of the paper are given as follows:

- The paper presents a unique pre-processing technology for liver disease prediction that combines the capabilities of Combination Wavelet as well as Bilateral Filter. This hybrid technique seeks to efficiently decrease noise and increase significant characteristics in medical pictures or data connected with liver illness, providing a stable platform for additional investigation.
- The research contains innovative feature extraction algorithms that take advantage of Convolutional Neural Networks (CNN) capabilities. By using CNNs' structured and spatial learning abilities, the study improves the extraction of complicated patterns and discriminative characteristics required for effective liver disease categorization.
- For categorization tasks, Extreme Learning Machines (ELM) are used. ELMs are noted for their high efficiency in learning and clarity, making them ideal for dealing with big datasets commonly found in clinical studies. The use of ELM provides an efficient and accurate categorization of liver disease according to extracted characteristics.
- The study uses the Grey Wolf Optimization technique to improve the classification model's accuracy. This optimization strategy, influenced by the social structure of grey wolves, attempts to improve the ELM model's convergence speed and accuracy, hence increasing the overall efficiency and efficacy of the liver disease forecasting system.
- The study assesses the suggested approach for detecting liver illness using important metrics such as precision, sensitivity, accuracy, and the F1 score. It employs 10-fold cross-validation to ensure robustness and gives a thorough grasp of the model's performance in various phases and settings, offering vital insights into its dependability and adaptability in everyday life medical contexts.

The rest of the section is organized as shown below. Section II illustrates literature works on liver disease prediction. Section III gives the Problem Statement. Section IV covers the proposed framework for the liver disease prediction. Section v illustrates the performance measures and summarizes the findings. Section VI provides the conclusion.

II. Related Works

Methods involving machine learning are being used more and more frequently in the modern day in the fields of medical research to identify numerous disorders, such as liver disease. This fatal illness claims a significant number of lives around the world [16]. Early therapy can be beneficial to the patient's recovery if the condition is diagnosed when it is in its early stages. Utilizing supervised machine learning categorization methods to detect liver disease is provided in the study article. In order to recognize the features of liver illness that are most significantly linked together, the study also used a least absolute contraction and selection operator characteristic selection approach on the dataset it had access to. The algorithms' estimations for the illness are evaluated for preciseness, sensitivity, accuracy, and f1-score values using 10-fold cross-validation. With LASSO included, it has been found that the decision tree approach performs optimally. A comparison with contemporary studies is also made to demonstrate the relevance of the suggested system. The possible difficulties of applying the results to various patient demographics or medical environments are not discussed in the research, though. It is critical to recognize the study's relevance to actual clinical practice's limits.

Individuals with chronic liver illness may experience acute-on-chronic liver failure, a clinical condition characterized by sudden hepatic decompensation and a significant short-term death rate. Organ failure, severe generalized inflammation, and a terrible outcome are its defining features [17]. Triaging and prognosticating patients with ACLF is feasible with certain liver-specific prognosis ratings and organ dysfunctions. The purpose of the research is to determine how well artificial neural networks, which functionally resemble biological neural systems, are capable of predicting the mortality associated with liver disease after ninety days. In the study, ANN was assessed in ACLF patients. A significant factor in accurately forecasting patients' short-term mortality is artificial neural networks. Its use with ACLF individuals can be beneficial since it simplifies and automated the process for recognizing individuals who are more likely to die. Artificial neural networks have a great deal of promise to help doctors make decisions, prioritize patients who need liver transplants right away, and forecast death and side effects. Even while the ANN model shows excellent precision, it might not be very interpretable. Understanding the variables that affect forecasts is essential for anyone working in the medical industry. Insufficient interpretability could undermine the model's acceptability and confidence among clinicians [18].

Even with the most recent and advanced equipment, medical professionals still have difficulties in accurately and early predicting liver disease in their patients. In the medical field, support vector machines are extensively utilized. Its effectiveness in generating quality diagnostic variables has been demonstrated. Support vector machine hyperparameter optimization may additionally enhance these outcomes. The suggested approach is predicated on using the crow search technique to optimize support vector machines. With the use of an improved support vector machine classifier, liver illness information from India may be accurately diagnosed. To demonstrate the effectiveness of the suggested method, a comparison with other comparable state-of-the-art algorithms is made. For every metric used for comparison, the efficacy of CSA-SVM is determined to be exceptional when compared to all other techniques. On the other hand, the dataset, code, and repeatability model are not made available in the work. In research related to science, repeatability and transparency are crucial [19].

Accessible medical facilities are essential for individuals in today's world, since healthcare is becoming an increasingly crucial component of daily life. The primary goal of this work is to use feature selection and categorization techniques in software engineering to forecast liver disease. The liver patient's dataset's various characteristics are utilized to forecast the degree of risk for liver disease. The Liver Patients dataset is used to test the accuracy of many methods of categorization. Numerous classifiers outputs are compared, both with and without the utilization of characteristic selection methods. Selection of characteristics and categorization estimation approaches based on software engineering concept are used in the creation of smart liver disease detection software. The article addresses using several categorization algorithms; however, it refrains from going into detail on how these algorithms' hyperparameters were adjusted or improved. Optimizing the parameters of the algorithm is crucial to attaining optimal outcomes [20].

Any condition that has the potential to damage, destroy, or impair the liver's normal function is referred to as liver disease. The death rate from liver illness has increased significantly in the world community. Numerous variables, including human behaviours, awareness problems, inadequate medical care, and delayed discovery, might be responsible for this. Early identification is essential to lower dangers and enhance treatment outcomes in order to address the ever-growing hazards posed by liver disease. As demonstrated in the present research, modern technologies like machine learning might be used to help improve its detection and diagnosis. To help in early identification, evaluation, and lowering of dangers and mortality related to the illness, a more effective approach for timely estimation of liver disease utilizing a hybrid extreme Gradient Boosting algorithm that includes hyperparameter adjustment is presented. The findings showed that the accuracy levels attained by the regression trees and chi-square automated interaction identification and categorization models were significantly higher than the traditional approach. The proposed treatment would help doctors and patients address the issue of liver damage, making sure that instances are identified earlier to avoid cirrhosis and to improve patient survival. The study demonstrated machine learning's assure in the medical field, particularly in the areas of illness monitoring and predictions [21].

The reviews of the literature investigate several machine learning techniques for the diagnosis and prognosis of liver disease. Stressing the value of early diagnosis, they address issues with interpretability and accuracy. Promising outcomes are demonstrated by strategies including CNN-ELM-GWO integration, CSA-SVM optimization, artificial neural networks for acute-on-chronic liver failure, and feature selection in intelligent software engineering applications. Even though these techniques show improved predictive power, there isn't much talk on how to apply these methods to specific demographics, how to interpret models, how to make code transparently available, and how to optimize algorithm parameters. Overall, the research highlights the promise of machine learning in enhancing the identification of liver illness, underscoring the necessity of more development and thorough investigation in clinical settings.

III. Problem Statement

Conventional machine learning algorithms for liver disease prediction have constraints concerning accessibility, transparency, and adaptation to a wide range of patient profiles and medical settings. These models frequently lack the potential to give useful information into ways to make decisions, limiting their use in clinical practice. Furthermore, more robust solutions are required to overcome the difficulties of noise as well as transparency in information from medical imaging [17]. The suggested technique, a hybrid CNN-ELM with GWO optimization, seeks to address these drawbacks. The CNN-ELM hybrid takes use of the capabilities of feature extraction and classification, while GWO optimization refines model hyperparameters. This comprehensive strategy enhances prediction accuracy while simultaneously addressing interpretability and transparency problems. Although the methods used with machine learning seem promising, there are certain obstacles that must be overcome before they can be successfully incorporated into clinical practice. The hybrid method's emphasis on optimizing learning and picture quality makes it a viable solution for obtaining accurate, early diagnosis of liver disease, eventually contributing to better outcomes for patients and lowering the worldwide effect of this life-threatening condition.

Existing methods for forecasting liver disease often rely solely on either CNNs or ELMs, but each approach has its limitations. CNNs excel at extracting hierarchical features from image data but may struggle with non-image data and require large amounts of labeled data for training. On the other hand, ELMs offer fast learning and good generalization but may not capture complex spatial relationships in image data effectively. Thus, there is a need for a hybrid approach that leverages the strengths of both CNNs and ELMs to improve the precision of liver disease forecasting. However, integrating these two disparate techniques poses challenges in terms of model architecture design, feature extraction, and optimization to ensure effective fusion of information from both modalities while mitigating overfitting and computational complexity.

IV. Liver Disease Prediction Using Convolutional Extreme Learning Machine

In the paper, an experimental analysis is conducted to thoroughly investigate the proposed method of employing a hybrid CNN and ELM for precision liver disease forecasting. To begin, a comprehensive dataset comprising a diverse range of liver disease cases, including various imaging modalities such as MRI, CT scans, and ultrasound images, as well as clinical data such as patient demographics, laboratory test results, and medical histories is curated. This dataset serves as the foundation for training, validating, and testing the hybrid model, ensuring that it is representative of real-world scenarios encountered in clinical practice.

Subsequently, the experimental setup is meticulously designed to systematically evaluate the performance of the hybrid CNN-ELM model against baseline methods and individual CNN and ELM models. The dataset is partitioned into training, validation, and testing sets, ensuring proper stratification to maintain the distributional characteristics of the data. The hyperparameters of the CNN and ELM components are then fine-tuned separately before integrating them into the hybrid framework. Throughout the experimentation process, rigorous cross-validation techniques are employed to mitigate potential biases and ensure the robustness of the findings. By systematically varying key experimental factors such as the size of the training dataset, the complexity of the model architecture, and the choice of hyperparameters, insights are gained into the effectiveness and scalability of the proposed method for precision liver disease forecasting. Ultimately, the experimental results provide empirical evidence supporting the utility and efficacy of the hybrid CNN-ELM approach, demonstrating its superiority over existing methods in accurately predicting liver disease outcomes.

This study's approach includes an extensive procedure for predicting liver disease using a dataset of 101 liver ultrasound images. In order to decrease noise and improve the clarity of the images preprocessing is employed using a hybrid technique that combined bilateral filtering and optimum wavelet transformation. Then, in order to extract crucial data from the ultrasound images, a Convolutional Neural Network with six convolutional layers, batch normalization, and max-pooling was created. Using this CNN as the feature extractor, 256 discriminant characteristics were produced for the prediction of liver disease. In order to take use of an Extreme Learning Machine's (ELM) accelerated learning speed and non-adjustable hidden node settings, these characteristics were subsequently introduced into the machine for categorization. By combining the processes of feature extraction and categorization, the hybrid CNN-ELM method improves accuracy. Lastly, to further enhance the effectiveness of the system, the CNN and ELM models' hyperparameters were adjusted using the Grey Wolf Optimization (GWO) technique. This all-encompassing method uses deep learning, metaheuristic optimization and sophisticated image processing to accurately forecast liver disease. The general framework of the proposed method is depicted in Fig. 1.

A. Data Collection

There are 101 liver ultrasound images in the collection. Of them, 57 have liver abnormalities such as FLD or heterogeneous liver texture, while 44 images show healthy subjects. A Toshiba Aplio 500 B-mode digital ultrasound scanner was used to obtain all of the images at the Multan Institute of Nuclear Medicine and Radiotherapy, located in Multan, Pakistan. For tissue harmonic imaging, a convex probe was utilized at a frequency of 5 MHz [22]. Each captured image had a resolution of 560 by 450 pixels and was stored as a bitmap file. The medical expert chose 114 64×64-pixel region of interest (ROIs) for categorization into normal and abnormal for these 101 images. These chosen ROIs serve as the basis for all further processing.

B. Hybridization of Optimal Wavelet and Bilateral Filter for Preprocessing

By hybridizing the best wavelet and bilateral filter for sophisticated preprocessing, liver disease prediction can be optimized, improving diagnostic accuracy and dependability. Ultrasound preprocessing is crucial because, in contrast to other imaging modalities like CT and MRI, ultrasound images are more probable to have noise components. Essentially, a speckle noise mostly distorts the ultrasound images. Higher categorization and segmentation accuracy cannot be obtained from a noisy image. For this reason, removing noise from medical ultrasound images is an essential step. For noise reduction in the study, bilateral filters and optimum wavelet hybridization were employed. The input image is first decomposed using the bi-orthogonal 3.7 wavelet transform in the study. After then, it produces four sub-bands, including LL, LH, HL, and HH. It uses the oppositional gravitational search algorithm (OGSA) to ideally acquire the wavelet coefficient in order to enhance the overall appearance of the denoised image. Newton's law of universal gravity and mass interactions serve as the foundation for gravitational search algorithms (GSAs), which are evolutionary heuristic optimization algorithms. To improve the search performance of the GSA algorithm, combining it with an adversarial learning method. Following the decomposition, the bilateral filter is applied to eliminate any noise from the input image. One nonlinear filter that appears to be effective in denoising images is the bilateral filter, which provides spatial averaging without flattening edges. Two Gaussian filters are combined to create this filter. Fig. 2 illustrates the preprocessing procedure.

C. Feature Extraction and Classification Using Convolutional Extreme Learning Machine

1) Feature extraction employing convolutional neural network: Feature extraction is the most critical part of the categorization issue as a model's achievement is based on how effectively the key characteristics from the ultrasound images are retrieved. To enhance the model's effectiveness in categorization, it is imperative to extract the favourable aspects that have enabled discrimination between the two classes. Convolutional Neural Network feature extraction includes employing a deep architecture including convolutional layers to find and highlight relevant patterns and features in data, hence improving analysis and classification. A method for converting higher dimensional information into lower dimensional, useful, and non-redundant information is called feature extraction. It makes it possible to process information more effectively and handle it better. Because the features for these pictures are more complex, a unique deep CNN has been developed to extract 256 significant characteristics for liver disease predictions utilizing the ultrasound images.

Fig. 3 shows the suggested CNN model. The suggested CNN model consists of six convolutional layers, with batch normalization and a max-pooling layer applied after two successive convolutional layers. Because batch normalization re-centres and re-scales the layer inputs, it improves the model's stability and speed of operation. In between two consecutive convolutional layers, there is a pooling layer. The most important elements of the images may be extracted by using max-pooling with 2 × 2 filters, which choose the biggest value from each cluster's whole neuron at the convolutional layers. Since the output is determined through adding the filters to each image tuple, the "SAME" padding has been added to the first two convolutional layers. Because border components frequently include important properties, they have been examined. Zero padding was used in the computation of the border components. The border components, however, were disregarded by the 'VALID' padding.

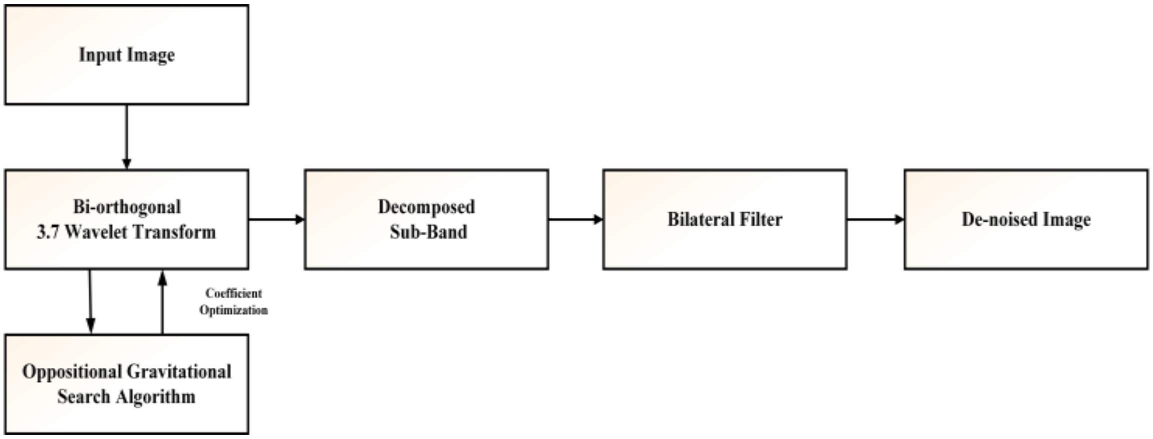

Fig. 2. Process of pre-processing.

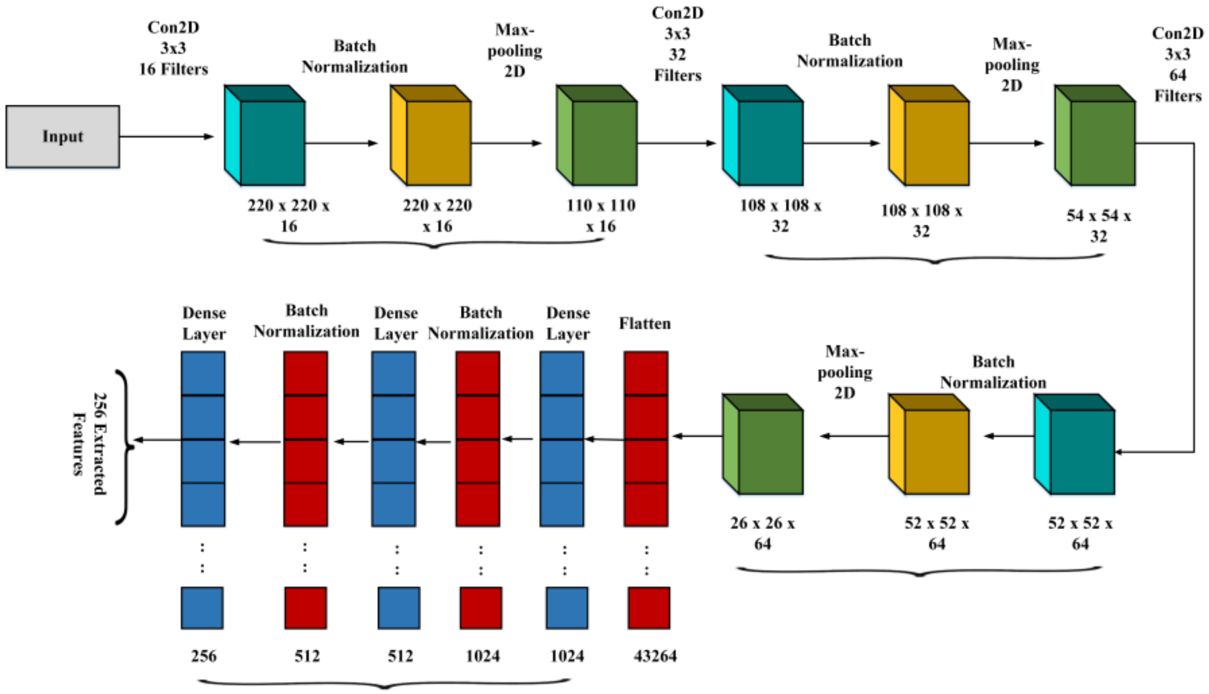

Fig. 3. Proposed CNN model.

ReLU has been used as an activation function in order to prevent the gradient from fading. There are two dropout layers that have been employed, one after the initial fully connected layer and the other after the last max-pooling layer. Both dropout layers have a probability of 0.5. Here, the training time increases significantly by using the dropout layers to reduce overfitting by frequently not training every node in every layer during the training stage. Because the Adam optimizer operates better while training on huge quantities of information and is extremely accurate for CNNs, it has been selected. Lastly, the 512 discriminant characteristics from each picture have been extracted using the final dense layer.

2) Classification using extreme learning machine: A feed-forward neural network with a number of layers of concealed nodes is called an ELM, and is typically used for pattern learning, regression, clustering, small estimate, compression as well, and categorization. It does not require the adjustment of hidden node variables, such as biases and weights. Conversely, the characteristics of hidden nodes can be transmitted down from their ancestors without modification, or they can be assigned at random and never altered. Comparing these models to networks trained using backpropagation, they learn far more quickly. In feed-forward neural networks, the learning process that is most frequently employed is backpropagation, which allows gradients to propagate from the output to the input. Backpropagation, however, has a lot of issues. In most applications, the training procedure takes an extended amount of time since biases and weights must be justified after each iteration. This approach ignores the weight magnitude in order to obtain maximum accuracy, which leads to decreased output over time. The update of weights and biases is no longer a barrier as a result of ELM, a feed-forward network. In order to maximize this model's overall effectiveness, it additionally concentrates on obtaining the lowest weight requirements in addition to the least training error. Simple alternatives are used for addressing the challenge of catching in local minima, hence eliminating such insignificant problems. Fig. 4 shows how ELM functions.

Let S be the arbitrary samples(q_i, r_i), and let $q_i = [q_{i1}, q_{i2}, \dots \dots q_{im}]^R \in P^m$ and $r_i = [r_{i1}, r_{i2}, \dots \dots r_{in}]^R \in P^n$, the standard single- concealed layer feedforward neural networks (SLFNs) with H concealed nodes and an activation function $f\ (\cdot)$ is expressed using Equation (1).

$$\sum_{u=1}^{H} w_u f_u(q_v) = \sum_{u=1}^{H} w_u f(b_u \times q_v + d_u) = o_v, (v = 1,2, \dots S) \qquad (1)$$

In this case, $b_i = [a_{i1}, a_{i2}, \dots \dots a_{im}]^R$ and $w_i = [w_{i1}, w_{i2}, \dots \dots w_{im}]^T$ is the weight vector that connects the u^{th} concealed node to the input nodes.d_i is the hidden node threshold, and $o_v = [o_{v1}, o_{v2}, \dots \dots o_{vm}]^R$ is the weight vector connecting the i^{th} concealed node to the output node. R is an example of an SLFN's v^{th} output vector.

Standard SLFNs with H concealed nodes and activation function $f\ \ (\cdot)$ can estimate these R illustrations with zero error, which means that $\sum_{v=1}^{H} \|o_v - r_v\| = 0$ and that there exist $\omega_u, b_i, and\ d_r$ such that

Using H hidden nodes and an activation function of $f\ (\cdot)$, standard SLFNs can calculate these R representations with zero error. This implies that $\sum_{v=1}^{H} \|o_v - r_v\| = 0$ and that $\omega_u, b_i, and\ d_r$ exist and it is given in Equation (2).

$$\sum_{v=1}^{H} w_u f(b_u \times q_v + d_u) = r_v, (v = 1,2, \dots S) \qquad (2)$$

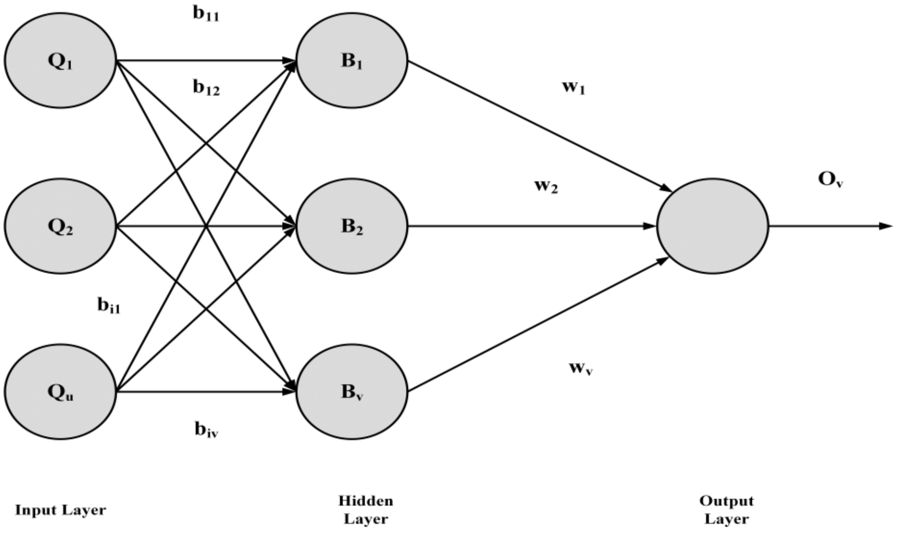

Fig. 4. Working of extreme learning machine

Equation (3), (4), (5) and (6) is an expanded version of the equation mentioned previously.

$$Nw = R \tag{3}$$

Where Equation (4),

$$N(a_1, \dots, a_H, d_1, \dots, d_H, x_1, \dots, x_H) = \begin{bmatrix} f(b_1 \times x_1 + d_1) & \dots & f(b_H \times x_1 + d_H) \\ \vdots & \dots & \vdots \\ f(b_1 \times x_S + d_1) & \dots & f(b_H \times q_S + d_H) \end{bmatrix}_{S \times H} \tag{4}$$

$$w = \begin{bmatrix} w_1^R \\ \vdots \\ . \\ w_M^R \end{bmatrix}_{H \times m} \tag{5}$$

$$R = \begin{bmatrix} r_1^R \\ \vdots \\ . \\ r_M^R \end{bmatrix}_{H \times m} \tag{6}$$

Where, the j^{th} column of N represents the outcome of the j^{th} hidden node based on inputs$x_1, x_2, \dots \dots x_S$, and N is referred to as a matrix of outputs of hidden layer. The linear technique's solution is given in Equation (7).

$$w = N^{-1}R \tag{7}$$

Where, the Moore–Penrose extended inverse of matrix N is denoted by N^{-1}.

Equation (8) defines the ELM's output function.

$$h(x) = q(x)w = q(x)N^{-1}R \tag{8}$$

3) Hybrid CNN-ELM algorithm: The Hybrid CNN-ELM technique combines the strengths of Extreme Learning Machine (ELM) for effective classification and Convolutional Neural Network (CNN) for reliable feature extraction from liver disease-related data. The combination of the CNN-ELM model improves liver disease prediction accuracy by combining CNN's effective visual feature extraction with ELM's fast learning. Its benefits include increased accuracy, faster learning, and more sensitivity, demonstrating efficiency in making exact predictions for liver illness and excellent performance and dependability. By giving a thorough method for identifying relevant characteristics and correctly categorizing liver disease a prerequisite for successful medical intervention this integration improves prognosis accuracy. Fig. 5 below provides a representation of the CNN-ELM hybrid algorithm. CNN and ELM are the two primary designs; CNN was once a characteristic extractor and ELM was a classifier. A single convolutional layer and a single pooling layer constitute the suggested CNN architecture. The study needs one hidden layer for the ELM, which is located between the input and output layers.

The image that reaches the convolutional layer is the first step in the CNN-ELM's main flow. Next, the image matrix that ReLU activates enters the pooling layer. Every processed image matrix then became a one-dimensional vector that could be entered into the ELM's input layer. The neural network uses a generic computation to generate the flattened image information before it enters the ELM concealed layer and is stimulated by the sigmoid function. Following the activation of values, the procedure proceeds to calculate the ELM from the layer that is concealed to the output layer, utilizing the following formula to obtain the categorization outcome, which is Equation (9).

$$W_{s-0} = (Y^R Y)^{-1} Y^R x \tag{9}$$

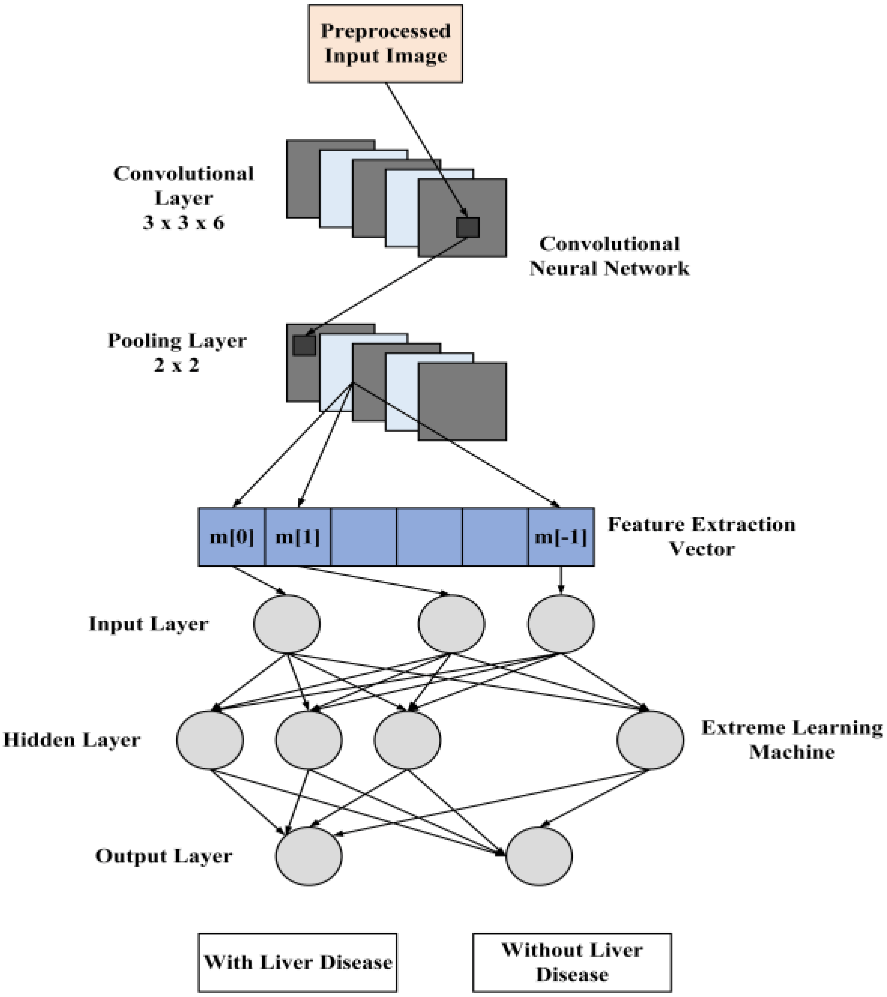

Fig. 5. CNN-ELM hybrid structure.

D. Grey Wolf Optimization Framework for Fine-tuning the Parameters

The Grey Wolf Optimization (GWO) framework optimizes the Convolutional Neural Network (CNN) and Extreme Learning Machine (ELM) components by fine-tuning parameters post-Hybrid CNN-ELM algorithm. Through appropriate parameter modifications in the feature extraction and classification process, the model is gradually enhanced for a better prognosis of liver illness, imitating the hunting behaviours of grey wolves. This iterative technique also improves accuracy. The GWO algorithm mimics the wolf's approach to hunting, which consists of circling the target and working together to make selections. Specifically, GWO is used to improve model hyperparameters including regularization factors, network design, and learning rates when it comes to parameter modifications. Two primary stages comprise the implementation of GWO in this hybrid CNN-ELM architecture. The CNN's architecture and hyperparameters, such as the number of convolutional layers, filter sizes, and learning rates, are first optimized using GWO. This ensures that pertinent characteristics are efficiently extracted from the ultrasound images by the CNN. The ELM model's hyperparameters, including the quantity of hidden nodes, activation functions, and regularization terms, are then adjusted using GWO. Through methodical parameter space exploration and utilizing wolves' cooperative decision-making approach, GWO assists in setting the system's feature extraction (CNN) and categorization (ELM) components, resulting in improved prediction accuracy for diseases of the liver.

GWO, a meta heuristic technique, was proposed [23]. The killing tactic and pack organization of grey wolves had an impact on the technique. Grey wolves live in packs and have an exceptionally hierarchical culture. Decision-making has been handed over to the alphas (α), the wolves' rulers. Alpha wolves are assisted in their tasks by beta (β) wolves, who fall within the following level. The victim in this system is the last individual, known as Omega (ω). If a wolf does not fit into any of the above-mentioned classifications, it is occasionally referred to as a delta (δ) wolf. In line with this well-defined hierarchy, grey wolves try to encircle a food supply, attack, and kill, then search for other prey. The way that wolves hunt is defined as follows: (i) a way to enclose prey; (ii) a way to locate and kill animals; and (iii) a way to battle a prey. Equations (10) and (11) describe how grey wolves circle their prey during a hunting expedition.

$$\vec{K} = \left|\vec{f} \cdot (\overrightarrow{X_w}(n) - \vec{X}(n)\right| \tag{10}$$

$$\vec{X}(n+1) = \overrightarrow{X_w}(n) - \vec{Q} \cdot \vec{K} \tag{11}$$

Where $\vec{X}$ depicts wolf's location in round configuration; $\overrightarrow{X_w}$is the prey's vector position; n is present time; $\vec{Q}$ and $\vec{K}$ are effective vectors that have the following definitions is shown in Equation (12) and (13).

Equations (12) and (13), where $\vec{X}$ represents the wolf's location in a circular configuration, $\overrightarrow{X_w}$ represents the prey's vector position, n denotes the current time, and $\vec{Q}$ and $\vec{K}$ represent effective vectors with the corresponding definitions.

$$\vec{Q} = 2\vec{p} \cdot \overrightarrow{c_1} - \vec{p} \tag{12}$$

$$\vec{f} = 2 \cdot \overrightarrow{c_2} \tag{13}$$

Random vectors equally distributed between 0 and 1 are included in $\overrightarrow{c_1}$ and $\overrightarrow{c_2}$ where the element d is progressively decreased from 2 to 0. The $\alpha, \beta, and\ \delta$ wolves are thought to comprehend it better since the location of the meal is never evident in advance. Equations (14), (15), and (16) are used to determine the victim's location by utilizing the wolves' positions.

$$\vec{K}_\alpha = \left|\vec{f}_1 \cdot \vec{X}_\alpha - \vec{X}\right|,\ \vec{K}_\beta = \left|\vec{f}_2 \cdot \vec{X}_\beta - \vec{X}\right|,\ \vec{K}_\delta = \left|\vec{f}_3 \cdot \vec{X}_\delta - \vec{X}\right| \tag{14}$$

$$\vec{X}_1 = \vec{X}_\alpha - \vec{Q}_1 \cdot \vec{X}_\alpha,\ \vec{X}_2 = \vec{X}_\beta - \vec{Q}_2 \cdot \vec{K}_\beta,\ \vec{X}_3 = \vec{X}_\delta - \vec{Q}_3 \cdot \vec{K}_\delta \tag{15}$$

$$\vec{X}(n+1) = \frac{\vec{X}_1 + \vec{X}_2 + \vec{X}_3}{3} \tag{16}$$

Assuming the study have an estimated position, the next step is to stalk the victim (exploitation). Since the condition of wolves grows closer to the prey's site as p in Equation (11) lowers from 2 to 0, the vector $\vec{Q}$ can be employed to achieve this purpose. Furthermore, variables f and Q both help preserve the method's exploring capabilities intact while eliminating the need for local averages. The variable f can change the location of food and the challenge of foraging, but it can also have an impact on a Q value greater than one, that is, $|Q| > 1$ which forces the wolves to stray from their food and seek it out. After applying the approach to a pack of wolves for a predetermined number of repetitions, Equation (13) will eventually show the location of the prey or the best area in the globe.

Grey Wolf Optimization (GWO) works in collaboration with Extreme Learning Machine (ELM) and Convolutional Neural Network (CNN) to forecast liver illness. GWO refines ELM and CNN hyperparameters by utilizing grey wolf searching algorithms. This two-stage optimization technique gradually increases the model's accuracy. By combining the capabilities of ELM along with CNN and GWO, the unified system of CNN-ELM-GWO obtains improved precision in liver disease categorization. The cooperative approach collaboration of GWO improves the model's resilience, allowing for effective adjustment and optimization, ultimately improving the system's overall effectiveness in forecasting.

V. Results and Discussion

The findings of the suggested method have been addressed in this section. A comprehensive process for predicting liver disease utilizing a collection of liver ultrasound images constitutes a component of the methodology used in this investigation. Preprocessing is done employing a hybrid approach that combines bilateral filtering and optimal wavelet transformation to minimize noise and increase the resolution of the image. Then, a CNN with six convolutional layers, batch normalization, and max pooling was developed in order to obtain important information from the ultrasound images. 256 discriminant features were generated for the prediction of liver disease employing this CNN as the feature extractor. These features were then added to the machine for classification in order to utilize an ELM enhanced learning speed and non-adjustable hidden node settings. The hybrid CNN-ELM technique enhances accuracy by fusing the feature extraction and classification procedures. Finally, the GWO approach was used to modify the hyperparameters of the CNN and ELM models in order to further improve the system's efficacy. This comprehensive approach forecasts liver disease accurately by combining deep learning, metaheuristic optimization and advanced image processing.

A. *Performance Evaluation*

Evaluation metrics are crucial for evaluating categorization performance. The method that is most frequently used for this is an accuracy measurement. The accuracy of a classifier for a given dataset may be determined by looking at the proportion of testing datasets that it properly classifies. Since selecting the best decisions is not possible simply by using the accuracy measure. Researchers also used a few more criteria to assess the classifier's effectiveness. Metrics including F1-score, accuracy, recall, and precision were utilized to evaluate the efficacy of the suggested approach. The following is a description of each measure's definition:

T_{pos} (True Positive) is used to describe the amount of information that has been effectively categorized.

The term $Fpos$ (False Positive) explains the amount of accurate information that was incorrectly categorized.

False negatives (F_{neg}) are situations where inaccurate information has been categorized as authentic.

The erroneous information values are categorized and referenced to as T_{neg} (True Negative).

1) Accuracy: The classifier's accuracy indicates how frequently it arrives at an appropriate conclusion. The ratio of accurate estimates to all other possible possibilities is known as accuracy. It is demonstrated by Equation (17).

$$Accuracy = \frac{T_{pos} + T_{neg}}{T_{pos} + T_{neg} + F_{pos} + F_{neg}} \tag{17}$$

2) Precision: The precision, or level of accuracy, of a classifier is employed to determine how many results are correctly classified. While lower precision results in many more false positives, higher accuracy reduces the number of false positives. The percentage of instances correctly assigned to all occurrences is known as precision. It is defined by Equation (18).

$$P = \frac{Tpos}{Tpos+Fpos} \tag{18}$$

3) Recall: The recall of a categorization defines its sensitivity, or the amount of pertinent information it produces. The overall amount of $Fneg$ is reduced through recall enhancement. The concept of recall is the ratio of correctly identified cases to the entire number of expected occurrences. This is demonstrable by Equation (19).

$$R = \frac{Tpos}{Tpos+Fneg} \tag{19}$$

4) F1-Score: The F1-Score, which is the weighted mean of recall and accuracy, is the result of combining recall and precision measures. It is characterised by Equation (20).

$$F1\ measure = \frac{2\times precision \times recall}{precision\times recall} \tag{20}$$

5) ROC Curve: In deep learning and machine learning, area under the ROC curve, or AUC, is a popular assessment statistic for binary categorization issues. The Area under the Curve (AOC) is a visual depiction of the Receiver Operating Characteristic (ROC) curve that shows how effective the binary recognition technique is. In a binary classified issue, the classifier determines whether the incoming data is part of a positive or negative division. The ROC curve displays the $Tpos$ vs. the F_{pos} for different categorization criteria. AOC values are between 0 and 1, where larger values indicate higher effectiveness. An optimum classifier has an AOC of one, whereas a totally randomized classifier has an AOC of 0.5. Since the approach takes into account every conceivable level of identification and provides just one statistic for comparing the effectiveness of various classifiers.

The training and testing accuracy levels of the suggested model throughout several training epochs are shown in Fig. 6. The model performed better and better during the course of 100 epochs of training. The training accuracy was 76.6% and the testing accuracy was 74.5% at the beginning, after only 10 epochs. However, training and testing accuracy levels steadily improved as the model learned and adjusted across additional training epochs. After 100 epochs of training, the model performed admirably, with a testing accuracy of 99.7% and a training accuracy of 99.3% towards the end of the procedure. With the testing accuracy showing the model's ability to produce correct predictions on data that has never been observed before and the training accuracy showing how well the model matches the training information, the graphic illustrates the model's capability to learn and generalize.

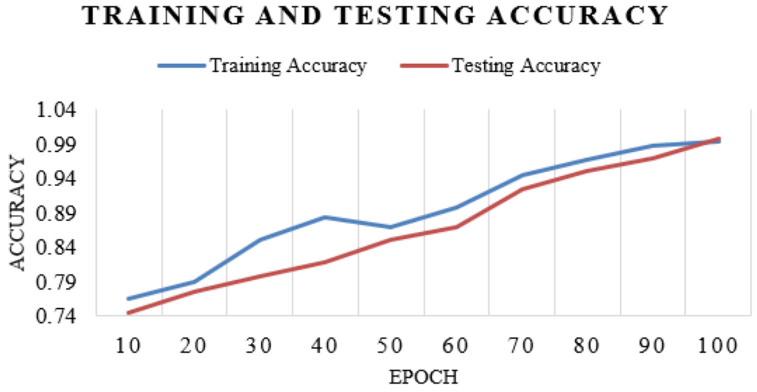

Fig. 6. Training and testing accuracy.

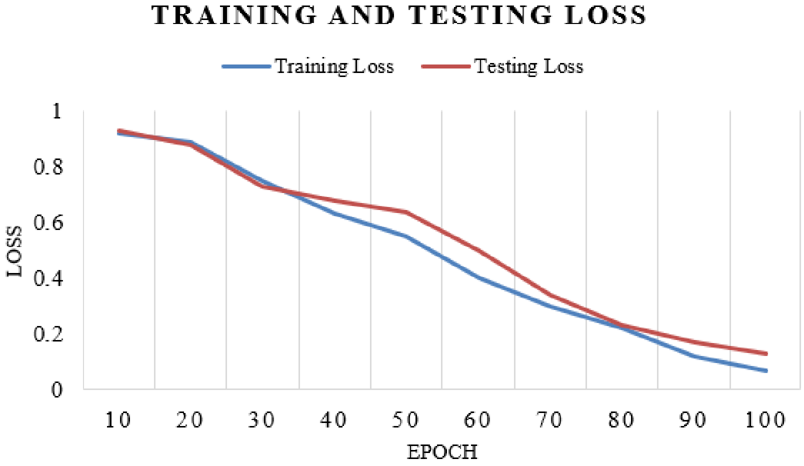

Fig. 7. Training and testing loss.

The suggested model's training and testing loss values are shown in Fig. 7 as it endures several training epochs. It displays the effectiveness of the model and its capacity to reduce mistake. The training loss was very significant at 0.92 at the start of training, with only 10 epochs, suggesting that the model's projections on the training information had a substantial margin of error. Concurrently, the testing loss was additionally slightly elevated at 0.93, indicating that the model did not perform much better on unobserved information. Training and testing losses reduced in an uninterrupted way as the model learned additional epochs, indicating that the model was getting better at generating predictions. The model reached low training and testing loss values of 0.07 and 0.13, respectively, towards the end of the training procedure, which lasted 100 epochs. These low loss values demonstrate the model's capacity to effectively decrease mistakes and generalize, since it has trained to generate extremely precise forecasts on both the training and testing datasets.

In terms of accuracy, precision, recall, and F1-Score for liver disease prediction, Table I and Fig. 8 provide a thorough comparison of the effectiveness of the proposed CNN-ELM-GWO method with other existing approaches, such as MLP (Multi-Layer Perceptron), RF (Random Forest), KNN (K-Nearest Neighbours), and NB (Naive Bayes). The outcomes show that the suggested CNN-ELM-GWO approach performs noticeably better than any other methods.

It demonstrates its capacity to provide incredibly precise forecasts by achieving an amazing accuracy of 99.7%. Additionally, the approach performs very well in terms of accuracy, recall, and F1-Score, all of which are continuously above 99%, indicating its resilience in accurately detecting liver disease cases. The conventional machine learning techniques, on the other hand, show consistently lower performance measures. These include MLP, RF, KNN, and NB. The table highlights the enhanced predictive capability of the suggested CNN-ELM-GWO technique, rendering it an exceptionally efficient and dependable solution for the categorization of liver illness.

The True Positive Rate and False Positive Rate for a binary classification model are shown at different threshold settings in Fig. 9. The fraction of real negative instances that the model mistakenly classifies as positive is represented by the False Positive Rate, which is displayed in the right column. The True Positive Rate shows the percentage of true positive cases that the model properly recognized. The True Positive Rate increases in conjunction with the incremental increase in the threshold from 0 to 0.6 for categorizing occurrences as positive, indicating enhanced sensitivity in accurately identifying positive situations. Concurrently, as the threshold gets more compressed more negative instances are mistakenly categorized as positive, according to the growing False Positive Rate. The relationship between True Positive and False Positive Rates at various categorization thresholds can potentially be evaluated using Fig. 9, which is a useful tool for choosing the best threshold for a particular categorization task.

TABLE I. COMPARISON OF PERFORMANCE OF PROPOSED METHOD WITH OTHER EXISTING APPROACHES

Methods	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
KNN [19]	62.90	56.60	55.80	56.19
NB [21]	69.20	70.15	60.16	64.53
MLP [16]	71.59	58.25	70.76	63.89
RF [17]	72.20	62.10	68.80	65.25
Proposed CNN-ELM-GWO	99.7	99.4	99.4	99.2

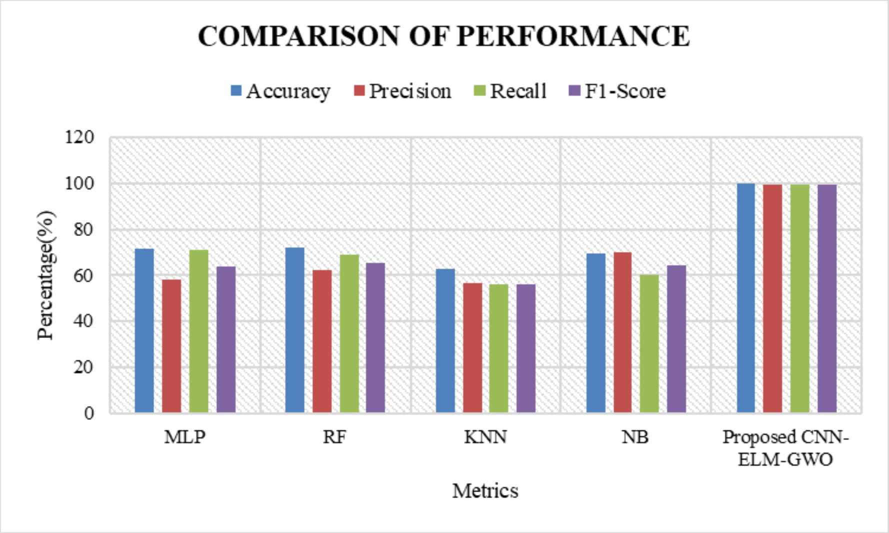

Fig. 8. Comparison of performance of proposed method with other existing approaches.

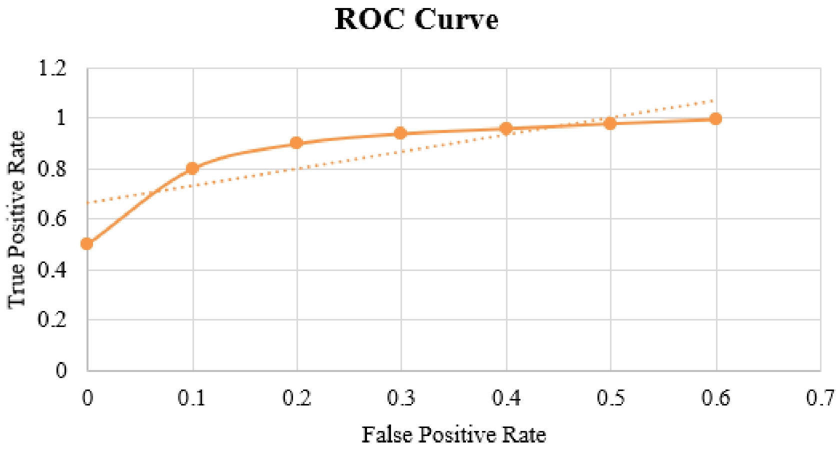

Fig. 9. ROC curve.

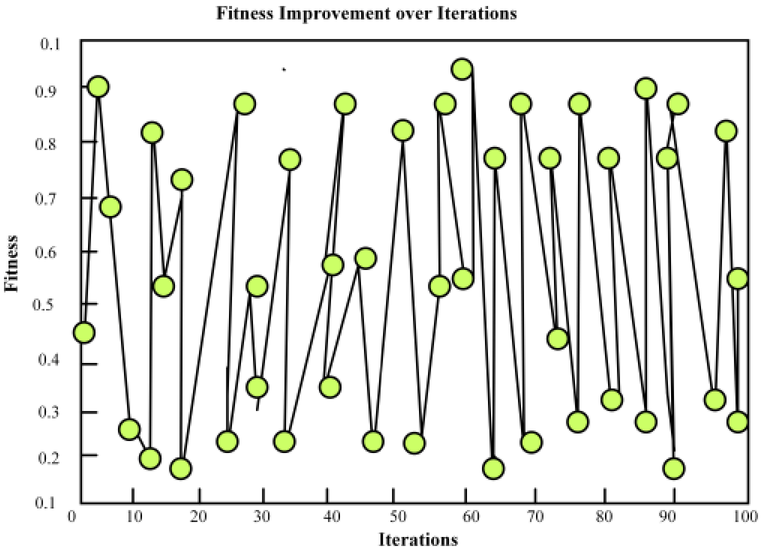

Fig. 10. Fitness improvement over iterations.

The progress of fitness improvement attained by the Grey Wolf Optimization method over several iterations is shown in Fig. 10 shows the Fitness Improvement over Iterations. It serves as an indication for how well the GWO algorithm improves its results over time. The y-axis denotes the fitness level of the algorithm's solutions, which is often a measure of how practically the algorithm's output is to the ideal or intended outcome. The x-axis shows the number of iterations or optimization cycles. The graph's decreasing pattern in fitness values as the iterations go on illustrates that the GWO algorithm is gradually improving and perfecting its solutions. While the decrease in fitness becomes lower in subsequent iterations, it indicates that achieving additional improvements is becoming more difficult.

The high decline in fitness early in the iterations shows that the algorithm is swiftly converging towards better solutions. This graph is crucial for assessing the effectiveness and pace of convergence of the GWO procedure. It also aids in deciding whether to stop the algorithm when the required level of fitness is attained.

A comprehensive evaluation of many datasets, including the Liver Disorder Dataset, Indian Liver Patient Dataset, and the Proposed Liver Ultrasound Images, is shown in Table II and Fig. 11 when compared to important performance metrics, such as accuracy, precision, recall, and F1-Score. The accuracy of the Liver Disorder Dataset was 70%, while the equivalent values for precision, recall, and F1-Score were 68%, 68%, and 69%, respectively. On the other hand, the Indian Liver Patient Dataset performed better, scoring 81% in terms of F1-Score, precision, and recall, and 80% in terms of accuracy. The suggested Liver Ultrasound Images dataset performed significantly superior to the others, with high values for precision, recall, and F1-Score (99.4%, 99.2%, and 99.7%, respectively). In comparison to current datasets, the proposed results demonstrate the higher predictive capabilities of the proposed technique when applied to Liver Ultrasound Images, indicating its potential as a diagnostic tool for liver illness.

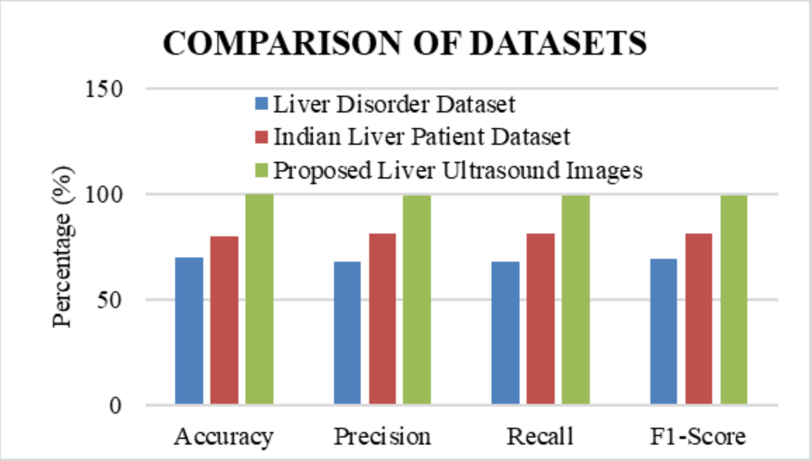

Fig. 11. Comparison of datasets of proposed method with other existing approaches.

TABLE II. COMPARISON OF DATASETS OF PROPOSED METHOD WITH OTHER EXISTING APPROACHES

Datasets	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
Liver Disorder Dataset	70	68	68	69
Indian Liver Patient Dataset	80	81	81	81
Proposed Liver Ultrasound Images	99.7	99.4	99.4	99.2

B. Discussion

The suggested liver disease prediction approach uses sophisticated preprocessing, bilateral filtering, and effective wavelet transformation to improve picture quality. When used with an ELM, a six-layer CNN retrieves 256 discriminant features, which optimizes learning. GWO improves the model's efficacy through hyperparameter tweaking. Evaluation measures show remarkable results, with 99.3% along with 99.7% accuracy in testing as well as training, respectively. Traditional constraints in liver disease forecasting include poor accessibility within artificial neural networks, feasible prejudices in dataset depiction, and the difficulty of current time application [20]. The CNN-ELM-GWO method surpasses previous approaches in a comparative analysis, demonstrating its dependability for liver disease categorization. Fitness Improvement across Iterations as well as ROC curve evaluations validate the model's effectiveness and convergence rate. This integrated technique shows potential for reliable liver disease prediction, outperforming alternative approaches. Despite its efficacy, the suggested liver disease prediction approach is limited. The dependence on ultrasound pictures may restrict applicability to other types of imaging. The model's effectiveness may be impacted by the dataset's consistency from a single medical institute. Furthermore, the substantial computational of the CNN-ELM-GWO method may provide difficulties for real-time applications. Further validation on varied datasets, as well as consideration of computing efficiency, are critical to assuring the method's broad application and usefulness. Future research should focus on improving the liver disease forecasting model. Exploring varied datasets collected by various medical institutes will result in greater application. Integrating with additional imaging modalities may increase generalization. Reducing computational complexity will improve real-time application practicality. Investigating interpretability and adding specific patient information might improve customized treatment techniques. Validation in clinical settings, as well as collaboration with healthcare experts, will help to make the model more practical, increasing its influence on liver disease detection and treatment.

VI. CONCLUSION AND FUTURE WORK

This study proposes a unique technique for identifying liver disease based on ultrasound images that takes advantage of the combined abilities of an integrated CNN-ELM-GWO model. The proposed technique surpasses standard machine learning methods with an incredible 99.7% accuracy, emphasizing the critical need for rapid and precise detection of liver disease, which is critical for effective patient treatment. The model provides an effective and innovative architecture by combining an Extreme Learning Machine for classification, a Convolutional Neural Network for feature extraction, and Grey Wolf Optimization for hyperparameter tuning. The CNN-ELM-GWO model's outstanding accuracy emphasizes the need for early detection, which is required for immediate treatment. This result may influence future research that employs advanced algorithms based on machine learning to enhance the identification of various illnesses, advancing the area of medical image evaluation. The findings motivate more research and advocate for more extensive deployment and development of the approach, which ought to result in improved patient outcomes and more informed healthcare decisions. Future research paths might include merging CT or MRI images alongside other types of imaging to increase diagnostic accuracy. Predictions might be made more personalized by using patient-specific information and medical history. The model's practical use would be enhanced if bigger, more diverse datasets were employed for assessment and practical clinical application. Obtaining credibility and adoption of the proposed technique by healthcare professionals necessitates exploring interpretability alternatives for the model's findings. Future research should focus on expanding the dataset to increase model generalization across different populations and medical circumstances. Furthermore, for practical significance, ongoing capability and incorporation into clinical processes must be studied. Improving the CNN-ELM-GWO model's comprehension and removing any biases will assist healthcare professionals in accepting and believing in it.

Personalized Recommendation Algorithm Based on Trajectory Mining Model in Intelligent Travel Route Planning

Jingya Shi, Qianyao Sun*
Department of Management Engineering,
Inner Mongolia Vocational and Technical College of Communications, Chifeng, 024005, China

***Abstract*—With the increasing demand for personalized travel, traditional travel route planning methods are no longer able to meet the diverse needs of users. In view of this, on the ground of the analysis of user trajectory data at the temporal and spatial levels, a new scenic spot recommendation model is proposed by combining personalized recommendation algorithms. Meanwhile, improved genetic algorithm and minimum spanning tree algorithm were introduced to adjust the structure of the personalized recommendation model. After matching the visit sequence of scenic spots, the final new personalized tourism route recommendation model was proposed. The experiment demonstrates that the optimal pause time for the personalized scenic spot recommendation model is 45 minutes, the pause distance is 15 meters, and the clustering radius is 500 meters. And the model has the highest accuracy in the Tok-10 testing environment, with a maximum value of 90%. In addition, the new personalized tourism route recommendation model has the highest accuracy of 85.6%, the highest recall rate of 88.7%, the highest F1 value of 92.4%, and an average convergence rate of 88.9%. In summary, the new scenic spot and route recommendation model proposed in the study can achieve more intelligent and personalized travel route planning, providing new guidance for the intelligent development of travel route recommendation.**

***Keywords*—Trajectory mining; personalized recommendations; travel routes; genetic algorithm; visiting sequence of scenic spots**

I. INTRODUCTION

As the boost of intelligent technology and people's increasing pursuit of personalized experiences, personalized recommendations have become an indispensable part of smart travel route planning to enhance the travel experience of travelers [1]. Many domestic and foreign researchers have conducted varying degrees of exploration to address the problems in this field. And relevant researchers have successively developed route planning techniques using global positioning systems and geographic information systems, and proposed personalized recommendation models for travel route planning [2]. These technical models can to some extent meet the line planning requirements of users. But with the diversification of demand, these technologies have also exposed issues such as slow real-time performance, poor accuracy, and low interactivity [3]. With the continuous development of trajectory mining technology, it is widely used in location services, logistics management, and other areas due to its superior real-time data monitoring and efficient data-driven characteristics [4]. In view of this, the study attempts to innovatively introduce user data trajectory mining technology on the basis of existing personalized recommendation algorithms. By analyzing the trajectory changes of users in time and space and adjusting the structure of recommendation algorithms, a new intelligent travel route planning model can be achieved. The rationale for this initiative lies in the lack of solutions in the current market that can provide personalized travel advice by taking into account users' historical behavioral data and real-time location information. Its significance is reflected in its ability to greatly enhance the user's travel experience and plan more personalized and reasonable travel routes for travelers through intelligent data analysis. The core research questions and objectives are closely centered on how to effectively use trajectory mining techniques to achieve personalized recommendations, as well as to improve algorithms to optimize the structure of the recommendation model to improve the accuracy and applicability of real-world travel planning. This directly addresses the core challenges in the field of intelligent travel planning, such as dealing with large spatio-temporal datasets and providing personalized travel recommendations that match user needs. The study first outlines the progress and limitations of related research and clarifies the research objectives. Then, the process of constructing a personalized recommendation model based on spatio-temporal trajectories is introduced. The validity of the model is verified through experiments. Finally, the research results are summarized, its application in the field of smart travel planning is discussed, and future research directions are proposed.

II. RELATED WORKS

With the continuous development of technology, intelligence has penetrated into every aspect of people's lives, and the travel industry is no exception. Yao Z et al. found that existing tourism route planning techniques have lower planning accuracy when facing complex environments. In view of this, the research team proposed a new travel route map matching method by combining mobile phone trajectory switching data under 5G networks. The experiment demonstrates that this method has high accuracy in planning user travel routes, and can switch to view parallel roads with smaller spacing at any time through mobile phones [5]. Huang F et al. found that existing travel route planning methods mainly focus on single planning problems for specific tasks, but cannot be applied to other tasks. In view of this, the research team proposed a multi task deep travel route planning framework by combining interest attributes, user preferences, and historical route data. The experimental results show that the framework is more effective in general path planning compared to similar planning methods and better meets user needs [6]. Khamsing N et al. proposed a novel optimal decision model for family tourism route planning by combining adaptive large neighborhood search method to explore the optimal solution in daily family tourism route planning problems. The experiment demonstrates that the average total travel cost of the optimal route under this decision model is relatively low, and the average travel satisfaction is 89% [7]. Zhu S proposed a multi-objective mixed linear programming model for circular tourism to maximize the utilization of tourist attractions by cyclists and minimize the total travel time by combining multi-objective algorithms. The experiment demonstrates that the model can continuously update the optimal path plan in actual bicycle tourism path planning, greatly increasing the service level of bicycle tourism path planning [8].

With the development of position sensing technology and the popularization of smart devices, the acquisition of trajectory data has become easier. The application fields of trajectory mining technology are also becoming increasingly widespread. To achieve accurate prediction of flight delays, Shao W et al. proposed a flight prediction model combining trajectory mining technology by utilizing various vehicle trajectories and related sensor data on the airport apron. The experimental results show that the error rate of the test results of the model in the simulation environment is only 2.56% [9]. Jiang L et al. found that when trajectory data shows low quality, the map matching effect cannot achieve satisfactory results. In view of this, the research team proposed a trajectory data augmentation technique that combines deep learning. The experiment demonstrates that this technology, with its superior migration mode and high-quality trajectory data expression, performs far better than other data augmentation models of the same type. With the rapid development of the Internet and the explosive growth of information, users often feel confused and anxious when facing massive amounts of information. The emergence of personalized recommendation algorithms provides an effective solution to this problem [10]. Chen et al. found that users find it difficult to find resources of interest in large capacity interactive calligraphy experience devices. In view of this, the research team proposed a hybrid personalized recommendation algorithm that combines content and coordinated filtering. The experiment demonstrates that the algorithm can accurately predict user selection, demonstrating certain effectiveness and superiority [11]. Zou F et al. found that traditional recommendation systems only ensure the accuracy of recommendations and lose the diversity of recommendations. In view of this, the research team proposed a two-stage recommendation algorithm that combines collaborative filtering (CF) and multi-objective teaching decomposition. The experiment demonstrates that this method is highly effective and efficient on the Movielens dataset [12].

In summary, although the previous studies have made progress in the field of smart travel planning, they mainly focus on static user preferences and do not sufficiently consider the complexity of spatio-temporal data, resulting in the inability to accurately capture users' real-time behaviors. In addition, traditional recommendation algorithms suffer from inefficiency when dealing with large-scale spatio-temporal trajectory data. And the study proposes a personalized recommendation algorithm using trajectory mining aims to address these limitations. By deeply analyzing users' spatio-temporal trajectory data, the algorithm can dynamically capture changes in user preferences. Combining the improved genetic algorithm and the minimum spanning tree algorithm, the study optimizes the recommendation structure, enhances the planning efficiency and accuracy, and achieves intelligent and personalized travel route planning, overcoming the key gaps in existing research.

III. Construction of a Smart Travel Route Planning Model Combining Trajectory Model and Personalized Recommendation Algorithm

To improve the overall performance of the final smart travel route planning model, this study first mined user trajectory data and obtained a recommendation model for the user's target attractions through personalized algorithm data analysis. Secondly, on the ground of the personalized attraction recommendation model, improvements were made and the final personalized intelligent travel route planning model was proposed.

A. *Construction of Personalized Recommendation Model on the Ground of Spatiotemporal Trajectory*

In this era of information explosion, personalized recommendations have become an important way for the public to obtain information and enjoy services [13]. Data mining is nothing but the best personalized recommendation method, among which web scraping technology is the most classic. This technology simulates browser behavior by writing programs to automatically obtain information on the Internet. The working steps are shown in Fig. 1.

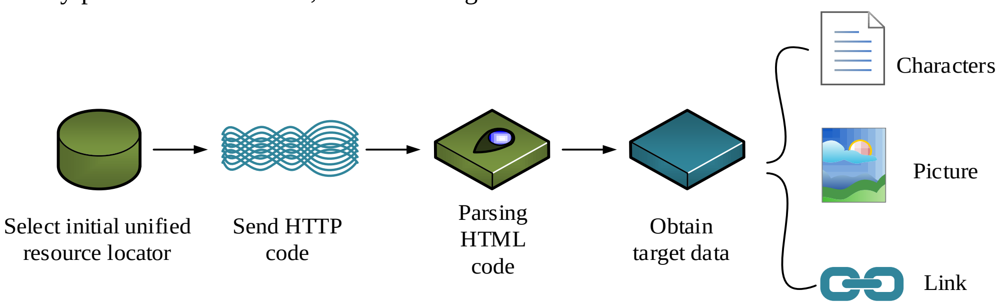

Fig. 1. Crawler technology workflow.

As shown in Fig. 1, the process of web crawling technology can be roughly divided into four steps. That is, sending HTTP code requests, parsing HTML code, extracting target data and storing it in the database. After completing the data crawler, the spatiotemporal trajectory analysis algorithm can analyze the user's temporal and spatial data, thereby strengthening the preference judgment of the user's historical data. The general spatiotemporal trajectory analysis uses Euclidean distance as a measurement unit to determine two similar data objects [14]. For different time nodes on two trajectories, it calculates the corresponding Euclidean distance meanwhile. The calculation formula for this process is shown in Eq. (1).

$$Dist(P,Q)=\sum_{i=1}^{n} dist(p_i,q_i) \tag{1}$$

In equation (1), p_i and q_i represent the nodes on the p and q trajectories at time point i, respectively, and n represents the total time point. The specific calculation of $dist(p_i,q_i)$ is shown in Eq. (2).

$$dist(p_i,q_i)=\sqrt{(p_{ix}-q_{ix})^2+(p_{iy}-q_{iy})^2} \tag{2}$$

In equation (2), (p_{ix},p_{iy}) represents the two-dimensional coordinates of node p_i, and (q_{ix},q_{iy}) represents the two-dimensional coordinates of node q_i. For the convenience of analysis, the Euclidean distance is converted into similarity calculation, as shown in Eq. (3).

$$sim(P,Q)=1-\frac{Dist(P,Q)}{\min(m,n)} \tag{3}$$

In equation (3), m and n represent the length values of trajectories p and q. Therefore, the similarity value interval after conversion can be determined as $(0,1)$, and the larger the value, the greater the similarity between the two trajectories. However, when faced with relatively large computational data, spatiotemporal trajectory analysis algorithms still face certain challenges. Therefore, the study focuses on scenic spots as recommendation objects and introduces the Mean Shift clustering algorithm to construct the user core access matrix [15]. It takes the location and time of each user's stay as a pause point, and after connecting all the pause points, it generates the user's travel path. The reasoning process of the pause point is shown in Eq. (4).

$$\begin{cases} L_i=\{l_1,l_2,l_3,\cdots,\mathrm{l_n}\} \\ \mathrm{l_n}=\{long_n,latt_n\} \end{cases} \tag{4}$$

In equation (4), L_i represents all pause records of the user, and $\mathrm{l_n}$ represents the pause location at time n. $long_n$ and $latt_n$ represent the longitude and latitude of the pause point, respectively. To avoid the calculation of the maximum number of nearest pause points, the study first excludes pause points for users with shorter time and distance, as shown in Eq. (5).

$$\begin{cases} \min long_s=\frac{1}{s}\sum_{i=1}^{s} long_i \\ \min latt_s=\frac{1}{s}\sum_{i=1}^{s} latt_i \end{cases} \tag{5}$$

In equation (5), s represents all pause points of shorter time and shorter distance. After excluding these pause points, the corresponding clustering labels are established using the Mean Shift clustering algorithm, and a user core access matrix is constructed [16]. The process of this matrix is shown in the Fig. 2.

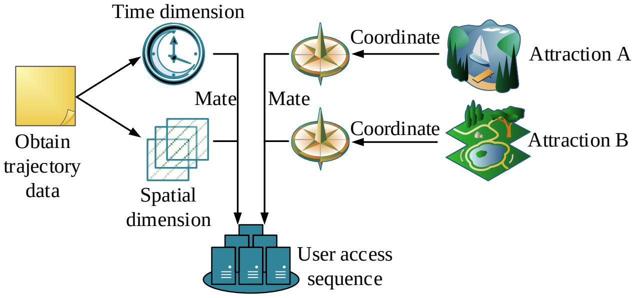

Fig. 2. User core access matrix flow.

As shown in Fig. 2, it first collects user access data and performs pause point analysis. It then establishes clustering labels for pause data in both temporal and spatial dimensions. In addition, it establishes a dataset of urban tourist attractions and classifies them through longitude and latitude coordinates [17]. Finally, it matches the pause data points after the label with tourist attractions, and the user access point at this point is the target point. It assumes that the vector of any point in the d-dimensional space after Mean Shift offset is shown in Eq. (6).

$$\begin{cases} M_h(x)=\frac{1}{k}\sum_{x_i\in S_h}(x_i-x) \\ S_h(x)=\{y\,|(y-x)(y-x)^T\le h^2\} \end{cases} \tag{6}$$

In equation (6), x_i is the i-th point, x represents any point, S_h is a low latitude sphere with a radius of h, T represents the number of iterations, and k represents the convergence center value. The entire algorithm obtains the final position that stabilizes the sphere by continuously approximating the offset vector towards any point x. The vector representation of the optimal point position at this time is shown in Eq. (7).

$$M_h(x)=\frac{\sum_{i=1}^{n} G(\frac{x_i-h}{h_i})w(x_i)(x_i-x)}{\sum_{i=1}^{n}\sum_{i=1}^{n} G(\frac{x_i-h}{h_i})w(x_i)} \tag{7}$$

In Eq. (7), h represents an element in a positive definite diagonal matrix, and h_i represents an element. $w(x_i)$ represents sample weight, $G(x)$ represents unit kernel function. To match the format of label data for the established visit sequence of scenic spots, the study abstracts any scenic spot, and the expression for this process is shown in Eq. (8).

$$\begin{cases} latt_{x`} \le latt_l \le latt_{y`} \\ long_{y`} \le long_l \le long_{x`} \end{cases} \tag{8}$$

In Eq. (8), l represents any pause point, and $(x`, y`)$ represents the coordinates of any scenic spot S_i. If the coordinate interval of the pause point is exactly within this range, it indicates that the pause point has visited scenic spot S_i. After similar frequent mining, a large number of tourist attraction visit sequences can be established, as shown in Eq. (9).

$$\varepsilon \le \frac{sum(l_{ck}^i \in vk)}{sum(ck)} \tag{9}$$

In equation (9), ε represents the critical threshold, ck represents the clustering sequence with many pause points, vk represents the clustering sequence with many pause points visiting scenic spot S_i, and l_{ck}^i represents the clustering pause point with time i. In summary, the personalized recommendation model combining user spatiotemporal trajectory data is shown in Fig. 3.

As shown in Fig. 3, the model structure can be roughly divided into five parts. The first part is the target users, who have unique ideas about tourist attractions and path planning and prefer intelligent recommendations. Secondly, through spatiotemporal trajectory analysis, the second part can be obtained, which is the user pause data sequence, which records the user's spatiotemporal historical browsing data. After analyzing these pause point data through clustering algorithms, the third part, namely the user access matrix, was obtained. Meanwhile, it establishes visit sequences for frequently followed attractions, and finally personalized recommendations are made by matching the similarity between the two.

B. Construction of Travel Route Planning Model Combining Personalized Recommendation Algorithm and Improved Genetic Algorithm

In practical life, to improve the functionality of personalized recommendation algorithms, this study not only needs to construct a recommendation model for scenic spots, but also needs to substantially propose route planning methods for these scenic spots [18]. To avoid user resistance caused by the large number of personalized recommended attractions and the scattered distribution of attractions, the study introduced the Minimum Spanning Tree (MST) clustering method to prioritize the segmentation of attractions. The schematic diagram of MST is shown in Fig. 4.

Fig. 4 shows that after MST segmentation, the distance between recommended tourist attractions within the established range is significantly reduced, enabling users to visit multiple tourist attractions within a specific time range, improving the quality of travel and saving time. In addition, unlike recommending tourist attractions, the problem of recommending tourist routes is complex and variable, that is, there are multiple possibilities for planning a route to a certain location [19]. Therefore, the study introduced an improved genetic algorithm (GA) on the ground of personalized recommendation algorithms. The traditional GA is shown in Fig. 1.

Fig. 5 shows that the traditional GA in tourism route planning can be roughly divided into nine steps, including recommending a set of tourist attractions, encoding recommended attractions, determining the population, calculating individual fitness, cross mutation, selecting the best individual, updating the population, condition judgment, and outputting the best route. Traditional GAs tend to construct initial populations randomly. If a smaller initial population appears, it will affect the convergence of subsequent algorithms, leading to lower individual fitness. Therefore, the study introduced the Greedy Algorithm to improve the initialization process of the population. The improved initialization population calculation formula is shown in Eq. (10).

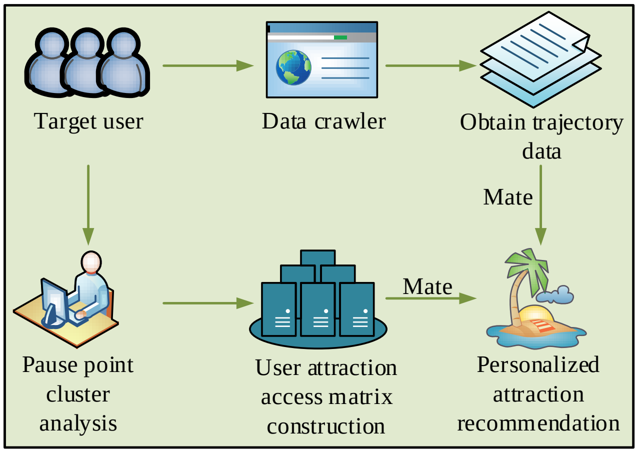
$$t_i = random(T), T - S \ne \varnothing \tag{10}$$

In Eq. (10), t_i represents a randomly selected attraction, T represents a set of all attractions, and S represents the initial population. At this point, the selection of nearby attractions is shown in Eq. (11).

$$\begin{cases} returnS = S.insert(t_j) \\ t_j = \min\_dis\tan ce(T - S, t_i) \end{cases} \tag{11}$$

In Eq. (11), t_j represents other attractions that are closer to the first attraction, and $S.insert(t_j)$ represents all the best individual attractions. At this point, to stabilize the individual's fitness value, the study introduced a fitness function with multiple constraints. This function includes two parts: the shortest route and the optimal access time. The fitness function calculation for the shortest route problem is shown in Eq. (12).

$$f_1(C) = \sum_{i=1}^{n`-1} d(c_i, c_{i+1}) + d(c_{n`}, c_1) \tag{12}$$



Target user
Data crawler
Obtain trajectory data
Mate

User attraction access matrix construction
Mate
Personalized attraction recommendation

Fig. 3. Personalized recommendation model structure diagram.

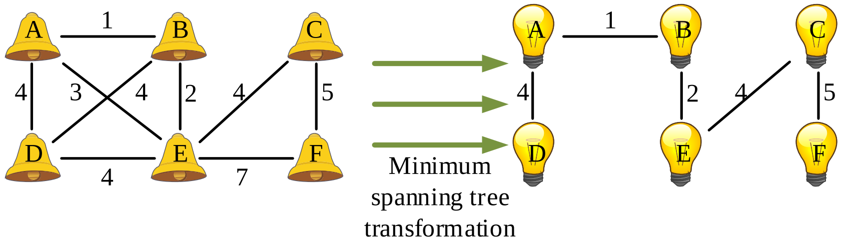

Fig. 4. MST schematic diagram.

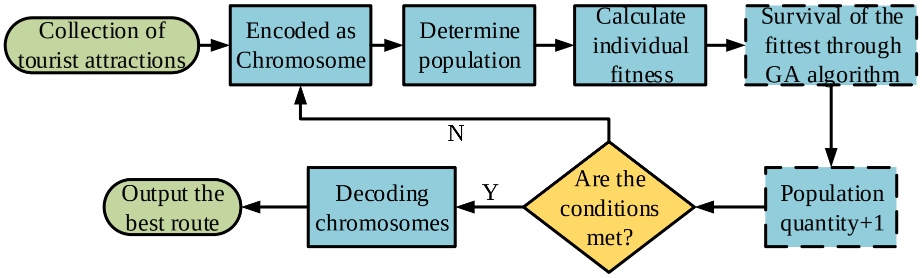

Fig. 5. The process of traditional GA.

In Eq. (12), C represents the collection of scenic spots, $n`$ represents the number of paths that satisfy user preferences, and $d(c_i, c_{i+1})$ represents the sum of distances between c_i and c_{i+1} paths. The optimal visit time needs to be planned in conjunction with the designated opening hours of the scenic spots. Due to the different opening hours of each scenic spot, the study divided the optimal visit time into three different visit times as dividing points [20]. The expression is shown in Eq. (13).

$$R(ci,t)=\begin{cases}\dfrac{2t-2t_{io}}{t_{ic}-t_{io}}, t_{io}\le t\le \dfrac{t_{io}+t_{ic}}{2}\\ \dfrac{2t_{ic}-2t}{t_{ic}-t_{io}}, \dfrac{t_{io}+t_{ic}}{2}\le t\le t_{ic}\\ 0, t<t_{io}\ \&\ t>t_{ic}\end{cases} \tag{13}$$

In Eq. (13), t_{io} represents the opening time of the attraction, t_{ic} represents the closing time of the attraction, c_i represents the attraction, and the user's visit time is t_i. Although the user's stay time at each attraction cannot be estimated, the visit time can be calculated on the ground of the popularity of the attraction. The calculation formula for conversion estimation is shown in Eq. (14).

$$t_{is}=T_N+\frac{count(c_i)}{\max(count(c_1),count(c_2),\cdots count(c_n))} \tag{14}$$

In equation (14), $count(c_i)$ represents the number of popular searches for attraction c_i, and T_N represents the time constant. By using this formula, the visit time and stay time of each attraction in a set of attractions C can be calculated. The optimal fitness function of the GA at this time is shown in Eq. (15).

$$\begin{cases}f_2(C)=\dfrac{1}{n}\sum_{i=1}^{n}R(c_i,t)\\ f(C)=\alpha f_1(C)+\beta f_2(C)\end{cases} \tag{15}$$

In Eq. (15), α and β represent the limiting weights of the fitness function for the shortest route and optimal access time, respectively. The best individual selected, crossed, mutated, and determined through GA is the optimal travel planning route for user needs. In summary, a new intelligent travel route recommendation model has been proposed by combining personalized recommendation algorithms and improved GAs. The structure of the model is shown in Fig. 6.

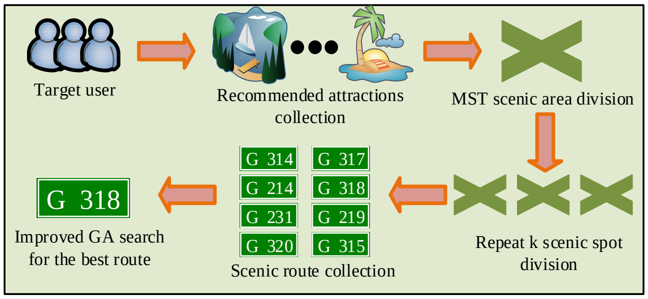

Fig. 6. Smart travel route recommendation model structure diagram

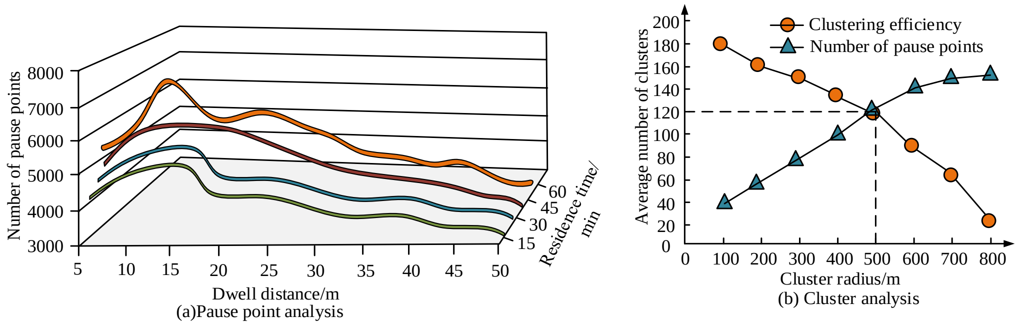
Fig. 6 shows that the entire smart travel route planning model consists of six parts. Firstly, it obtains the trajectory data information of the target user and their preferences. Secondly, it filters the target node set that best meets the user's needs through a personalized recommendation model. Then, the MST algorithm is used to divide the collection of scenic spots into regions, to reduce the recommended target. After k repeated reductions, multiple path planning schemes were finally obtained to determine the distance between scenic spots. Finally, an improved GA algorithm was used to select the optimal path set and output the best route.

IV. Results

To verify the performance of the proposed new intelligent personalized recommendation model, this study first tested the scenic spot recommendation model and determined the optimal operating parameters of the algorithm. Then it was compared with similar recommendation algorithms. In addition, the new tourism route recommendation model was tested to determine its optimal iteration times and fitness function values. It was also compared with similar recommendation models.

A. *Test Results of Scenic Spot Recommendation Model*

To verify the performance of the personalized scenic spot recommendation model proposed in the study, which combines trajectory data mining, the Windows 10 operating system was used, with an Intel Core 2.5Hz dual core CPU and 16GB of memory. To ensure the authenticity of the test, this study used a global dataset of tourist attractions and routes. This dataset contains information on various tourist attractions and related routes from around the world, totaling approximately 100000 pieces. It divides the dataset into training and testing sets in an 8:2 ratio, and the training set sample data is used to train personalized recommendation models. The study introduced two variables, dwell time and dwell distance, to analyze the pause points of users. Meanwhile, to prevent model training caused by too large or too small variables, the study sets the dwell time to within 1 hour and the dwell distance to within 50 meters. In addition, the Mean Shift clustering radius is used as a variable to detect changes in the number of clusters. The specific test results are shown in Fig. 7.



(a)Pause point analysis

(b) Cluster analysis

Fig. 7. Pause point analysis and cluster analysis parameter testing.

Fig. 7(a) shows the changes in the pause time and pause distance parameters of the pause point, and Fig. 7(b) shows the changes in the clustering radius parameters of the clustering analysis. As shown in Fig. 7, the pause change curve is most stable when the pause time is 45 minutes, and the maximum number of pauses at this time is 6000 when the pause distance is 18 meters. In addition, as the clustering radius increases, the average number of clusters gradually decreases, while the number of pause points gradually increases. When the clustering radius is 500m, that is, at the intersection, the number of the two performs best. Therefore, in subsequent research, the set parameters include a pause time of 45 minutes, a pause distance of 15 meters, and a clustering radius of 500 meters. To verify the performance difference between the personalized recommendation model proposed in the study and existing models of the same type, Tok-k accuracy was used as a reference indicator. This indicator represents the proportion of the top k results with the highest probability in the prediction results that contain correct labels, for example, Tok-5 is a test environment with 5 recommended sets. Meanwhile, the content attribute personalized recommendation model (Item based), rating personalized recommendation model (Mark based), and image personalized recommendation model (Graphics based) were introduced. The test results are shown in Fig. 8.

Fig. 8 shows that the personalized recommendation method proposed in the study generally has high accuracy in three testing environments. The highest accuracy rate in Tok-5 is 88% for the study of the proposed model, 90% for the study of the proposed model in Tok-10, and 84% for the study of the proposed model in Tok-15. In Tok-10, the accuracy of the proposed model is 33% higher than that of the content attribute personalized recommendation model and 31% higher than that of the rating personalized recommendation model. In summary, it can be concluded that the personalized scenic spot recommendation model proposed in the study, which combines temporal and spatial data trajectory mining, has the best performance. In addition, with accuracy, recall, F1 value, and recommendation similarity as reference indicators, comparative tests were continued on the four models, and the test results are shown in Table I.

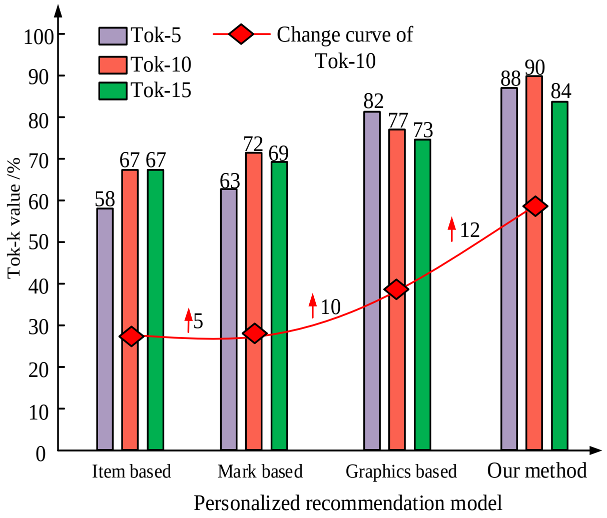


Fig. 8. Comparison results of Tok-k accuracy of different recommendation models.

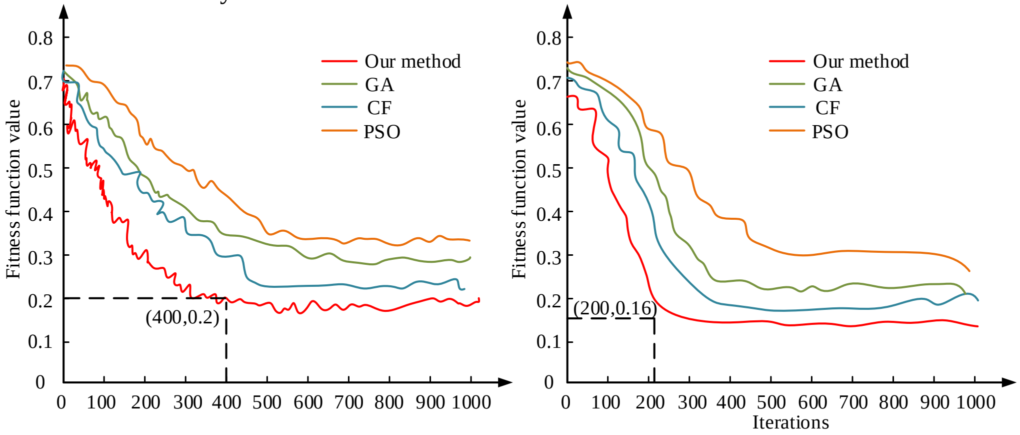
TABLE I. COMPARATIVE TEST RESULTS OF PERSONALIZED RECOMMENDATION MODELS

Model	Precision/%	Recall/%	F1/%	Recommended similarity/%
Item based	64.8	65.3	67.1	68.5
Mark based	68.4	71.6	74.8	77.9
Graphics based	74.2	75.3	76.7	79.5
Our method	82.4	84.6	85.9	89.3

As can be seen from Table I, the Item based model has generally low indicators in various categories, with its highest P value of 64.8%, highest R value of 65.3%, highest F1 value of 67.1%, and highest recommendation similarity of 68.5%. In contrast, the study proposes that the recommendation model performs the best, with the highest accuracy of 82.4%, the highest recall of 84.6%, the highest F1 value of 85.9%, and the highest recommendation similarity of 89.3%. The values rose 17.6%, 19.3%, 18.8% and 20.8% respectively compared to the lowest Item based model. In summary, it once again proves that the model proposed in the study is more in line with user choices, with higher recommendation and usage rates.

B. Test Results of Route Recommendation Model

Due to the introduction of an improved GA on the ground of personalized recommendation algorithms, this study first tested the iterative performance of the improved GA. It determines the optimal number of iterations and fitness function values to facilitate subsequent model testing. In addition, to enhance the reliability of testing, traditional GAs, CF, and Particle Swarm Optimization (PSO) were introduced in the study. These algorithms were tested separately on the training and testing sets, and the test results are shown in Fig. 9.



(a)Training set

(b)Test set

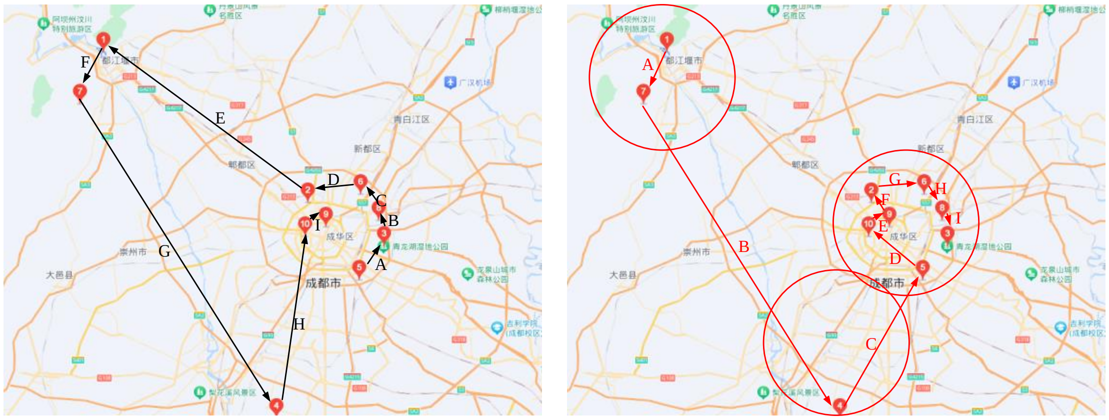
Fig. 9. Iterative performance testing of different optimization algorithms.

Fig. 9(a) shows the iterative performance test results of four optimization algorithms in the training set. Fig. 9(b) shows the iterative performance test results of four optimization algorithms in the test set. Fig. 9 shows that as the number of iterations increases, the fitness function values of all four algorithms decrease, but then tend to stabilize. The results of the training set show that the lowest fitness function value of the proposed model is 0.2 when the number of iterations is 400. In the test set, when the number of iterations is 200, the fitness function value at this point is as low as 0.16. Therefore, it is necessary for subsequent research to use the number of iterations and fitness function values as benchmarks for performance testing of similar algorithms. It conducts 50 repeated experiments on four algorithms and takes the average of the ratio of the optimal solutions obtained each time as the average convergence degree of the algorithm. Meanwhile, it continues to introduce three reference indicators: accuracy, recall, and F1 value. The test results are shown in Table II.

As can be seen in Table II, the GA algorithm has the worst performance in the metrics test, with the highest accuracy of 54.2%, the highest recall of 57.6%, the highest F1 value of 64.5%, and an average convergence of 58.8%. This is followed by PSO algorithm and CF algorithm, while the personalized recommendation algorithm proposed in the study has the highest accuracy of 85.6%, the highest recall of 88.7%, the highest F1 value of 92.4%, and the average convergence of 88.9%. To more accurately reflect the performance of the personalized tourism route recommendation model proposed in the study, the top 10 popular tourist attractions in Chengdu were selected as the target locations. They are 1) Dujiangyan Irrigation Project Water Conservancy Project, 2) Chengdu Happy Valley, 3) Qinglong Lake Park, 4) Huanglongxi Ancient Town, 5) Sansheng Flower Town Scenic Spot, 6) Giant Panda Base, 7) Qingcheng Mountain, 8) Eastern Suburb Memory, 9) Wenshu Academy and 10) Du Fu Thatched Cottage. The actual results of comparing the traditional personalized recommendation route and the new personalized recommendation route are shown in Fig. 10.

TABLE II. PERFORMANCE TEST RESULTS OF DIFFERENT OPTIMIZATION ALGORITHMS

Model	Precision/%	Recall/%	F1/%	Mean Convergence %
GA	54.2	57.6	64.5	58.8
PSO	68.4	73.2	79.5	73.7
CF	74.2	77.7	83.8	78.6
Our method	85.6	88.7	92.4	88.9



(a)Traditional personalized recommendation routes

(b)New personalized recommendation route

Fig. 10. Comparison results of personalized recommended routes.

Fig. 10(a) shows the traditional personalized recommendation route, and Fig. 10(b) shows the new personalized recommendation route. As shown in Fig. 10, the traditional personalized recommendation route connects 10 scenic spots in pairs, resulting in a total of nine moving paths, represented by black arrows. The red arrow represents the new recommended path, while the red circle tends to indicate the clustering range of scenic spots. Considering the actual situation, the maximum daily travel itinerary for users is three scenic spots. Therefore, under traditional methods, the longest crossing path for the same day's itinerary takes more time and is not conducive to users choosing fixed accommodation. The new personalized recommendation path can select at least one and at most seven stopping points within the established stopping range, and set accommodation at the center of each circle for the most convenient. In summary, the new personalized tourism path recommendation model proposed in the study performs better.

V. Conclusion

Traditional travel planning methods are usually static, only considering the user's departure and destination, without considering the user's actual behavior and real-time location. In view of this, the study established a personalized recommendation model through mean shift clustering and trajectory analysis after decomposing user trajectory data in time and space. After introducing an improved GA, a new intelligent personalized tourism route recommendation model was proposed. The experimental results show that when the pause time is 45 minutes, the pause distance is 15 meters, and the clustering radius is 500 meters, the performance of the personalized scenic spot recommendation model is the best. Compared to personalized recommendation models of the same type, the proposed model has the highest accuracy in the Tok-10 testing environment, with a maximum value of 90%. The highest model accuracy is 82.4%, the highest recall is 84.6%, the highest F1 value is 85.9%, and the highest recommended similarity is 89.3%. In addition, testing the personalized travel recommendation route model found that compared to other models, the new route recommendation model proposed in this study has the lowest iteration number of 200 and a fitness function value of 0.16. The highest accuracy of model recommendation is 85.6%, the highest recall is 88.7%, the highest F1 value is 92.4%, and the average convergence is 88.9%. Simulation tests have shown that the new model can plan more reasonable and suitable routes for the public's actual tourism, save time on route expenses, and facilitate accommodation arrangements. In summary, the new personalized attraction and route recommendation model proposed in the study can improve the effectiveness and experience of travel planning and meet user needs. However, this study only analyzed user trajectories from time and space sequences. Further research can add more user characteristic information analysis, such as subjective requirements and preferences, to enhance the completeness of the study.

VI. Discussion

The study successfully constructed a novel attraction recommendation model and travel route recommendation model by introducing improved genetic algorithm and minimum spanning tree algorithm. These two personalized recommendation models perform well in several performance metrics, highlighting their potential in the field of intelligent travel route planning. First, the optimal stopping time of the personalized attraction recommendation model is set to 45 minutes, the stopping distance is 15 meters, and the clustering radius is 500 meters when these parameters are optimized to ensure that the model can accurately capture the actual user behaviors and deviations. In particular, the model achieves 90% accuracy in the Tok-10 test environment, which is much higher than traditional personalized recommendation models, such as content attribute personalized recommendation model, rating personalized recommendation model, and image personalized recommendation model. This result emphasizes the importance of spatio-temporal trajectory data analysis in improving recommendation accuracy, and also demonstrates that the performance of recommender systems can be significantly improved by fine-grained user behavior analysis. In addition, the personalized travel route recommendation model has the highest accuracy of 85.6%, recall of 88.7%, F1 value of 92.4%, and average convergence of 88.9%. These metrics not only reflect the model's efficiency and accuracy in the field of travel route recommendation, but also show the effectiveness of the improved genetic algorithm in dealing with complex route planning problems. By introducing the greedy algorithm to optimize the initial population and adopting the fitness function with multiple constraints, the study successfully improves the convergence speed of the algorithm and the quality of recommendations. However, there are still some potential challenges and limitations of these models. First, although the studies have achieved significant results in specific datasets and environments, their generalization capabilities still need to be validated in a wider range of scenarios and complex user behavior patterns. In addition, the performance of the model relies heavily on high-quality spatio-temporal trajectory data, and thus, it may face challenges of privacy protection and data security in data collection and processing. In response to the above discussion, future research could further explore the application of the model in different cultural and geographic contexts to validate its generalization ability. Second, considering the importance of data privacy and security, future work should focus more on the anonymization of user data and the application of encryption techniques. Finally, given the diversity and dynamics of user preferences, the development of more flexible and adaptive models will be the key to improving the accuracy and user satisfaction of recommender systems.

Animation Media Art Teaching Design Based on Big Data Fusion Technology

Rongjuan Wang*, Yiran Tao
Department of Global Fine Art, Graduate School, Kyonggi University, Suwon 16227, Korea

***Abstract*—Animation, as an ancient art expression form, still has vigorous development, and the need for animation talents in society is increasing daily. This study first introduces the definition of animation and the development of animation at home and abroad. After that, the classification regression tree algorithm's principle and function theorem are described. This study divides the data into original and new animations based on big data fusion technology. It establishes a media art teaching system with search, recommendation, and playback as the three cores. Additionally, iteration is used to calculate the optimal hidden semantic matrix, a comparison is made between the benefits and drawbacks of the Sigmoid, Tanh, and ReLU functions, and lastly, the activation function chosen is the ReLU function. Compared with the loss value in the ideal case, the experimental findings comply with the likely criteria, and the categorical regression tree algorithm model predicts an error rate that falls within acceptable limits. Practically speaking, it is known that when the hidden factor dimension is 12, the system model works best for characterizing animation features. The comparison shows that the non-standard collaborative filtering recommendation system is inferior to the recommendations filtered by the categorical regression tree algorithm model. Following the use of the system, the students' drawing and directing abilities, animation scope, and animation appreciation level all improved significantly. The questionnaire survey concluded that the teachers and students of animation majors in universities were satisfied with the system.**

Keywords*—Animation; big data fusion; classification regression tree algorithm; media art teaching system

I. Introduction

The rapid development of computer technology has generated massive amounts of data, and studying these data has, in turn, driven the development of computer technology. It is the era of big data, and along with the widespread appeal of computer mainframes and mobile phones, the amount of people using the Internet has increased dramatically. The Internet has grown quickly as a result of technological developments as well, and humans today have access to hundreds or even thousands of times more data every day than they did in ancient and modern times [1]. According to an International Data Institute report, the global data volume is anticipated to reach 56 ZB by 2030 [2]. Animation from the generation and dissemination also took advantage of the development of the Internet. They grew up, and the larger bandwidth and more rapid transmission speed both provide a broad and excellent soil for the production and dissemination of animation.

The abundance of information brings about convenience and the issue of information overload, which presents a significant obstacle for information producers and consumers. For information producers, the material they create can easily be submerged in the data of the Internet and cannot distinguish themselves from others. Much information is available to users, and separating the helpful information is challenging, wasting time and energy [3]. Universities and art colleges are particularly affected by this issue, where educators have access to abundant information resources and must exert significant effort to select only those appropriate for their teaching. Students still lack a solid worldview, life perspective, and set of values, and separating the good from the bad is challenging when they receive mixed information [4]. The search, recommendation, and viewing system for teaching animation media art based on big data fusion technology came into being, providing some convenience to users; however, users' needs are different; exceptionally productive students have specific needs for searching, recommending, and viewing animation media data [5]. Throughout human history, animation has evolved to communicate ideas and express feelings. From the eight-legged bison drawn in caves by ancient humans with black charcoal in the late Paleolithic to the continuous wrestling figure on ancient Egyptian frescoes, from the first animated film "Enchanted Pictures" to Disney's first 3D animated film "Toy Story," animation development has now become a spiritual totem for some people [6]– [9]. As the era of Big Data storage began to emerge, revolutionary changes have also occurred in the distribution media. From videotape to CD-ROM until nowadays, online streaming media and animation present accessibility, convenience, and technological development [10]. For art college and university students, especially those majoring in animation-related disciplines, searching, recommending, and viewing animation media data are critical to developing skills and knowledge.

Currently, in daily life, search engines are used extensively to offer consumers both basic and extensive search services in addition to conventional search engines. The integrated search engines of music, video streaming, social media, and knowledge quiz software are also receiving increasing attention, and this software faces a great challenge in delivering more accurate, timely, and convenient search results. The animation art teaching system assisted by big data fusion technology is the search function is the foundation, and only when the animation data is well searched can educators and learners gain from it [11]. Suggestion systems, on the other hand, have evolved from streaming services and are now most frequently applied in e-commerce applications for product recommendations. In the animation market application, incorporating a suggestion system enhances the positive user experience while increasing active product users. User stickiness rises as a result, making users see more different styles of animation works and eventually greatly improving commercial interests [12]. Viewing animation is as important for art students in animation as it is for college students in other majors to read material related to their major, sometimes even watching and analyzing an animation frame by frame, and this way of learning is called pulling a film [13]. In the teaching system of art colleges and universities, with the ongoing advancement and use of computer convergence technology, the animation industry has favored the provision of online streaming media, where teachers and students can easily access resources in a variety of ways, such as online viewing and downloading using video websites and cell phone applications. However, animation databases are becoming larger and larger, and college art students have to spend a lot of time and effort to find the right animation for them. In the past, Users were limited to searching using keywords such as name, director, and style of animation, and the variations among users were not considered in the search results, leading to biased results [14].

The growing volume of animation data and demand from students and faculty in universities and art colleges demonstrates a more difficult task for studying animation search, recommendation, and viewing algorithms. Conventional recommendation systems fall into three main categories: content-based recommendations, collaborative filtering, and hybrid recommendations combining the two. Even so, these three categories of fundamental suggestion methods have been advanced; they have serious issues, like sluggish startup times [15]–[17]. In addition, the recommendation based on sentiment status, which developed along with social media, has also come into view with the public, resulting from the computer industry's deep learning and thorough exploration of the possible interests of users. This paper, based on classification regression tree theory, starts by analyzing the characteristic data of art school teachers and students and their animation preferences to design a motion search system with accuracy, personalized music recommendation, and a virtual reality viewing system, which is the goal of every art college and which can also greatly facilitate teaching and learning for teachers and students daily. Thus, it has significant research implications and a wide range of potential applications.

1) This study innovatively applies the classification regression tree algorithm to preprocess animation data and train models. By replacing the predicted feature coefficients, effective data preprocessing of the animation video library was achieved, improving the prediction accuracy and stability of the model.

2) The research system fully utilizes the advantages of big data to achieve precise satisfaction of personalized needs of students, improving teaching effectiveness and student satisfaction. The construction of this system provides a new teaching mode and method for animation media art teaching.

3) This study compared the advantages and disadvantages of Sigmoid, Tanh, and ReLU functions, and ultimately chose ReLU function as the activation function. This choice effectively improves the training speed and performance of the model, providing strong support for the optimization of animation media art teaching models.

This study establishes a media art teaching system based on big data fusion technology, with search, recommendation, and playback as the three core elements. Section II of the study elaborates on the background of animation media art teaching based on big data fusion technology. Section III elaborates on the analysis of animation and animation applications. Animation has evolved from two-dimensional to three-dimensional, expanding its application scope. The principle and selection analysis of the classification regression tree algorithm were conducted in Section IV. The implicit feature analysis of iterative animation was conducted through a mixed model of user behavior and animation media data information. Section V conducted teaching system practice and effectiveness analysis. It uses the predicted feature coefficients of the input classification regression tree algorithm to preprocess the data of the animation video library. Through animation teaching classroom tests, the abilities of college students in related majors were tested. It shows that animation students have improved their drawing and directing skills, their animation scope, and their appreciation of animation through this system. Section VI summarizes the entire text. Students majoring in animation production have significantly improved their drawing and directing skills, animation scope, and animation appreciation level by using this system.

II. Related Work

Previous research has provided us with the development history of animation media art, from early hand drawn animation to modern digital production technology. These studies help us understand the evolution of anime art and how it combines with technological advancements. Previous research has contributed to the theoretical framework of animation art instructional design. They explore different teaching methods, strategies, and evaluation methods, providing us with a solid theoretical foundation to better design and implement animation media art teaching. With the rapid development of technologies such as big data and artificial intelligence, previous research has explored the application of these technologies in other fields. These studies provide us with valuable experience, enabling us to draw on and apply them to the design of animation media art teaching.

The teaching design of animation media art based on big data fusion technology is expected to bring revolutionary changes to animation education. Through the analysis and mining of big data, we can more accurately understand the learning needs and effects of students, and thus design more personalized and efficient teaching methods. Through real-time data analysis and feedback, we can adjust teaching strategies in a timely manner to ensure optimal teaching outcomes. This will help cultivate students' creative thinking and practical abilities, and provide more high-quality talents for the animation industry. Animation is the art of "tricking" the eye, based on the same principle as film. It is a film technique that uses the visual residuals of the human eye to create the illusion of movement of objects within the image by showing still images at a fixed frequency [18]. From its inception, animation has been an art form, combining many characteristics of painting and film. Because the location and environment do not limit it, it expresses a wild imagination.

It has broadened its application after the development of animation from a two-dimensional to a three-dimensional stage. In contemporary times, animation is mainly used in entertainment, with animated episodes, movies, special effects, games, and animated advertisements being its main battleground [19]. The field of animated episodes has been gaining momentum in recent years, making hundreds of millions of people feel the charm of animation by disseminating online streaming applications such as Netflix, Disney, and HBO. Among them, "Love, Death and Robots" has created high ratings and topics with its mature animation technology, deep thought expression, and amazing picture expression, the masterpiece of American animation in the new century [20]. Digital fusion technology, including virtual reality, augmented reality, mixed reality, etc., has brought unprecedented possibilities to visual art design. These technologies not only enable designers to present artworks in unprecedented ways, but also allow audiences to immerse themselves in them and gain a more profound artistic experience. Therefore, studying the impact of digital fusion technology on visual art design is of great significance for promoting the development of the art and design field [21]. The basic principle of digital fusion technology is to combine digital information with the physical world to create a brand new and immersive experience. For example, virtual reality technology simulates a three-dimensional environment, allowing users to experience the virtual world firsthand; Augmented reality technology adds digital elements to the real world, allowing users to observe the world from a completely new perspective [22]. These technologies provide a new creative medium for visual art design, enabling designers to present artworks in unprecedented ways. The emergence of digital fusion technology has brought about a profound transformation in the form of visual art design. Firstly, designers can utilize these technologies to create more realistic and immersive works of art. Secondly, digital fusion technology allows artworks to no longer be limited to traditional media such as painting and sculpture, but can be extended to various media such as virtual space and mobile devices. In addition, digital fusion technology also provides designers with richer creative tools, such as 3D modeling software, virtual reality editors, etc., allowing them to create art works in unprecedented ways [23].

In contrast, China's animation has been in a disadvantaged position in the world since the peak of "The Greatest Showman" at the beginning of the country's founding. The animation industry is far below Japan and the United States in terms of both artistic value and commercial output. Creating animation with its national characteristics, artistic expression, and commercial value has become the challenge and goal of every animation producer in China. This study aims to use big data fusion technology to create an animation teaching system suitable for university teachers and students and make some contribution to the animation education industry. Fig. 1 shows promotional images for the "Love, Death, Robot" series of animations.

Fig. 1. Promotional image for the animated series from Love, Death, and Robots.

III. Principle and Selection of Classification Regression Tree Algorithm

The definite regression tree algorithm is built depending on the prior distribution, the distribution set before the experiment. From there, it extracts the posterior distribution of the sample. So, the regression tree theorem, also known as the posterior probability, is the likelihood that event N will occur under the conditions after event M, which the following equation can express.

$$P(M|N) = \frac{P(M \cap N)}{P(N)} \tag{1}$$

The posterior probability is not the same as the joint or prior probability, which is the likelihood of two occurrences, M and N, occurring simultaneously. And the opposite of the posterior probability is the prior probability. The prior probability can be marginalized to give an alternative expression for the regression classification tree algorithm. That is, according to the equation that follows.

$$P(M|N) = \frac{P(M|N)P(M)}{P(N)} \tag{2}$$

Where $P(M|N)$ denotes the probability of event M occurring in the case of event N.

A. Overall Design of Animation Media Art Teaching System

The recommendation systems for text, photos, music, and videos have extensively used the categorical regression tree algorithm. This study of an animation content search, recommendation, and viewing system for art school college students is a hybrid model of recommendation based on user behavior and animation media data information. Using a classification regression tree algorithm, this search's primary objective and recommendation are to compute the implicit features of the animation media data iteratively and then obtain the data's low-dimensional vector information through marginalization. This low-dimensional vector information can be included in the search to enhance the search results. By merging them with the implicit preference features of college-going users, reasonable recommendations can also be generated. This experiment directly extracts the image and audio features from the animation video files. This can overcome the cold start problem and be as close to the user's innate sense of animation as possible. The conventional matrix-based decomposition model is the basis for this hybrid system and is enhanced algorithmically. Fig. 2 below shows the general flowchart for system design.

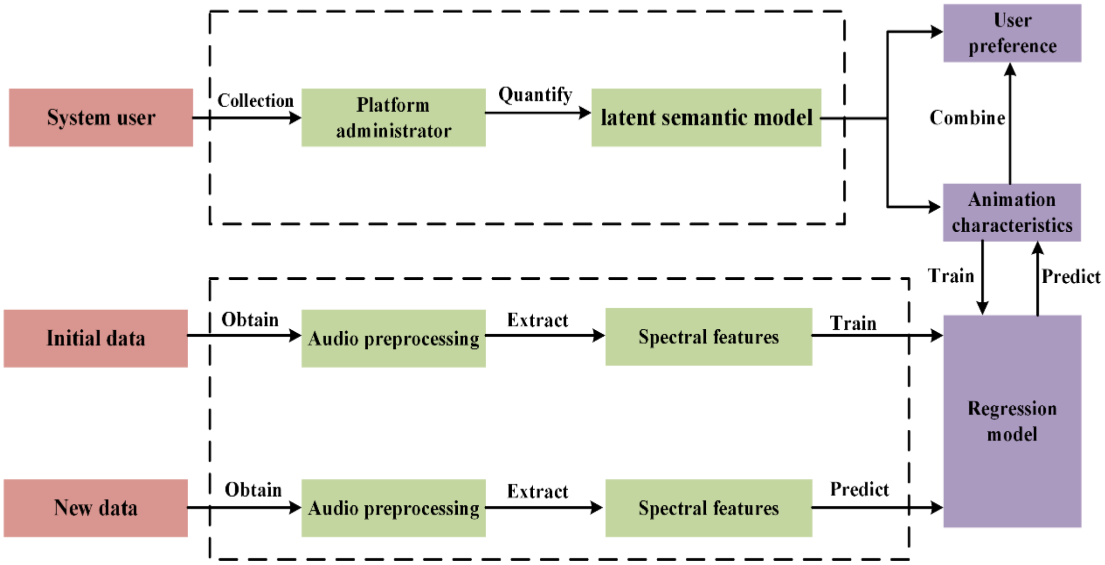

Fig. 2. Flow chart of the overall design of the animation big data management system for college students.

The above figure shows that the model utilizes a covert semantic matrix to map user-hidden traits and animation video data into a common space using a classification regression algorithm, ultimately producing search and recommendation outcomes. The animation media art teaching data system in colleges and universities includes a user features module, animation video information, a search engine module, a recommendation algorithm module, and virtual reality playback equipment. The user features module's primary responsibility is to gather and preserve student users' behavioral history data within the system and then build their preference models. Based on the extracted features, the search engine module generates customized search results for the user. Calculating the degree of matching between student users and hidden features is done through the recommendation algorithm module, and, finally, recommend animations that may be interesting for users dynamically. The two main components of the entire system operation are classification regression tree model training and search recommendation, and the processes of acquisition, prediction, and aggregation are indicated by arrows in the figure. The steps involved in the particular process are as follows: first, the system uses online streaming software to gather historical user behaviors from students and unifies them for analysis using a suitable semantic matrix; then, the raw animation data are reduced and processed to extract image and spectral features; a dynamic model of classification regression tree is constructed using the data collected in the first two stages, and then the resulting data are input and continuously. Finally, if new animation data is added to the system, the same reduction is performed to obtain the image and spectral features. Then, the perfect model is used to determine how interested a user is in the new animation data in combination with the preference of college students and, ultimately, decide whether to advise the user to use it.

The system must also categorize the original and updated animation data. Traditional animation is based on name, director, scriptwriter, Production Company, and file format classification. Certain similarities can be found in the automatic animation classification method based on style and emotion. The classification regression tree algorithm must be run through three steps to extract features, select the best features, and classify training. The two, nevertheless, are very different because the traditional animation classification's qualitative features are not the same as the abstract definitions of style and emotion in animation. The style and emotion of animation are derived from the subjective emotions of humans, which is a high-level way to describe the experience. Style is established by classifying different artists while making animation works by their starting points and common points. It can serve as a condensed synopsis of the works of specific directors. The topic of animation is expressed through emotion, has a decisive role in evoking the viewers' feelings about the work, and can be utilized as a concise overview of the shared aspects of certain animation works according to the plot and character portrayal stereotypes. More animation materials are available now than ever due to the animation business's growth. It is of great importance for the advancement of the animation industry that animation students and teachers quickly connect and enumerate the information using style and emotion classification when searching for the required materials, which determines the merits of a certain database. The animations produced by the same animation director at different times may have different ideas or styles. The subset of features obtained by the categorical regression tree algorithm can be used to form a hierarchical relationship map for the perception of animation works according to style and emotion.

B. *Constructing the Hidden Semantic Matrix*

A Basic Factorization Matrix (BFM) is the hidden semantic matrix used in the animation media art teaching system, which does not break down the scoring matrix into the form of a product of three matrices, in contrast to the traditional singular decomposition matrix. Multiple users and multiple items are broken down into a matrix of hidden factors corresponding to users and a matrix of hidden factors corresponding to items by the hidden semantic matrix. Complementing the original matrix is not necessary, and finally, the matrix is fitted using the obtained hidden factors to obtain the predicted scores. The following equation can express this process.

$$\overline{R}_{\alpha\times\beta} \approx R^2_{\alpha\times\beta} = P_{\alpha\times k} Q^T_{\beta\times k} \tag{3}$$

The variables $^{\alpha}$ andβ represent the number of student users and music, respectively, and$R^2_{\alpha\times\beta}$represent the approximate square matrix resulting from the decomposition of the two matrices, which goes by the name of the estimated rating matrix. The following formula can be used to determine an animation's expected rating by a student user.

$$p_u q_i^T = \sum_{k=1}^{K} p_{uk} q_{ki} \tag{4}$$

The hidden semantic matrix can be well used to represent the student user's preference for the underlying features of the animation using hidden factors and lessening the matrix decomposition's complexity. The next step requires computing the two hidden factor matrices$P$ and,Q initializing them, and then iterating them continuously using the stochastic gradient ascent method until a local optimum is reached. The following equation can define the error in scoring for every student user.

$$e_{ui}^2 = (r_{ui} - \sum_{k=1}^{K} p_{uk} q_{ki})^2 \tag{5}$$

This study uses squared error to lessen the discrepancy between the expected and real scores by first defining the loss function as:

$$arg\,L\,oss = \sum e_{ui}^2 = \sum (r_{ui} - \sum_{k=1}^{K} p_{uk} q_{ki})^2 \tag{6}$$

Then, find the direction of the current value's positive gradient, using two directional variables to differentiate.

$$\begin{cases} \frac{\partial}{\partial p_{uk}} e_{ui}^2 = -2q_{ki} = -2e_{ui}q_{ki} \\ \frac{\partial}{\partial q_{uk}} e_{ui}^2 = -2q_{ki} = -2e_{ui}q_{ki} \end{cases} \tag{7}$$

Update rules are then developed to iterate over the gradient up direction.

$$\begin{cases} p_{uk} + a\frac{\partial}{\partial p_{uk}} e_{ui}^2 = p_{uk} + 2ae_{ui}q_{ki} \\ q_{uk} + a\frac{\partial}{\partial q_{uk}} e_{ui}^2 = q_{uk} + 2ae_{ui}p_{ki} \end{cases} \tag{8}$$

The constant in the above equation a determines the machine learning rate's minimum value, which is a small value. The gradient ascent process is iterative and continuously performed until the smallest possible mistake is made. When the loss function's error is smaller, the iteration comes to an end, then the set threshold$e$ and two matrices are ultimately obtained as:

$$E = \sum e_{ui}^2 = \sum (r_{ui} - \sum_{k=1}^{K} p_{uk} q_{ki})^2 \leq e \tag{9}$$

Hidden Semantic Matrix Decomposition can be done using the simplest formula above, and direct loss function optimization cannot be performed due to the ease with which overfitting may result. In this experiment, the original loss function is subjected to the regularization term, i.e., after introducing regularization, the loss function is expressed as follows:

$$e_{ui}^2 = (r_{ui} - \sum_{k=1}^{K} p_{uk} q_{ki})^2 + \lambda(\|p_u\|^2 + \|q_i\|^2) \tag{10}$$

$$arg\,L\,oss = \sum \begin{matrix} (r_{ui} - \sum_{k=1}^{K} p_{uk} q_{ki})^2 + \lambda(\|p_u\|^2 \\ +\|q_i\|^2) \end{matrix} \tag{11}$$

Systematic experiments can be obtained from the above equationλ, which is the regularization parameter. Eq. (11) is optimized using the stochastic gradient ascent method, where the two matrices are first biased.

$$\frac{\partial Loss}{\partial p_{uk}} = -2(r_{ui} - \sum_{k=1}^{K} p_{uk} q_{ki})q_{ki} + 2\lambda p_{uk} \tag{12}$$

$$\frac{\partial Loss}{\partial q_{ki}} = -2(r_{ui} - \sum_{k=1}^{K} p_{uk} q_{ki})p_{uk} + 2\lambda q_{ki} \tag{13}$$

The parameters in the above two equationsp_{uk} andq_{ki} are then iteratively optimized along the minimum value of the velocity rise using alternating least squares to obtain the optimal parameter values.

$$\overrightarrow{p_{uk}} = p_{uk} + a(e_{ui}q_{ki} - \lambda p_{uk}) \tag{14}$$

$$\overrightarrow{q_{ki}} = q_{ki} + a(e_{ui}p_{uk} - \lambda q_{ki}) \tag{15}$$

The ideal hidden semantic matrix is thus obtained in this manner for this experiment, after which the parameter selection of the required functions is carried out.

C. Activation Function of Animation Media Art Teaching System

Without an activation function, the categorical regression tree model would only be comparable to a linear regression model and be unable to solve logical problems that were more complicated. When activation functions are introduced, a nonlinear processing model replaces the monotonic model in dynamic systems, allowing more complex animated data to be represented and computed. Today, Sigmoid, Tanh, and ReLU functions are the three monotonic functions that are most commonly utilized, and the accompanying function diagrams are displayed Fig. 3 below.

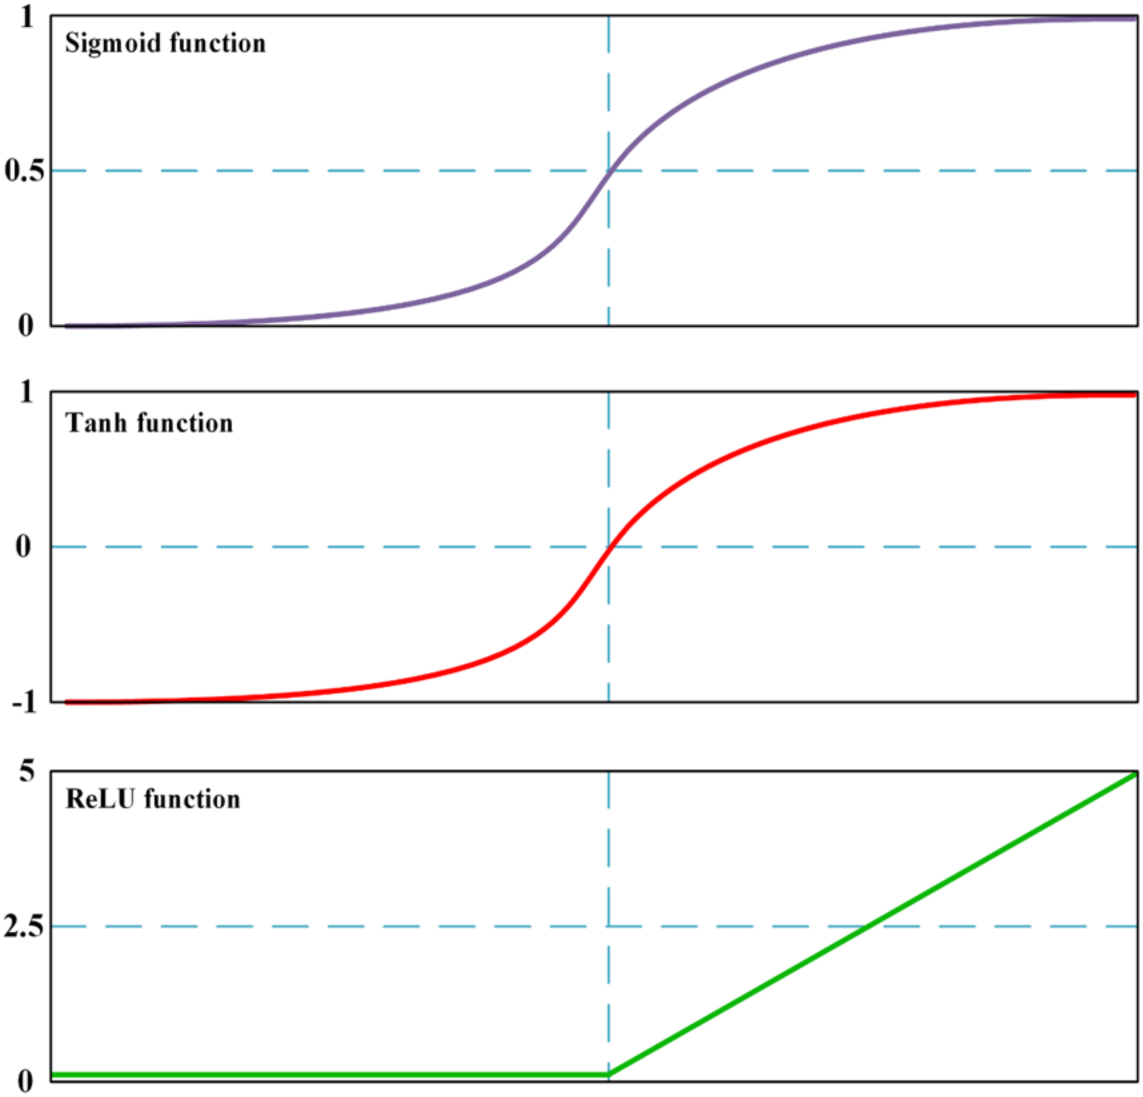

Fig. 3. Schematic diagram of Sigmoid function, Tanh function, and ReLU function.

The selection of various activation functions applied to the animation art teaching system will affect prediction and training, impacting the search and recommendation outcomes. Significant errors are produced when computing large amounts of data using the Tanh or Sigmoid functions; when utilizing the ReLU activation function, convergence can occur rapidly, reducing computation costs and increasing training effectiveness. Additionally, the ReLU function's gradient is constant for the dynamic deep animation art model, and unlike in the case of the Sigmoid function, there is no gradient disappearance. Consequently, as previously indicated, the activation function of this study's animation art teaching system is ultimately chosen to be the ReLU function.

IV. Teaching System Practice and Results Analysis

In computer deep learning, numerous open-source, free benchmark databases are available at home and abroad, but most are text, images, audio, and surveillance videos. In most cases, copyright ownership is involved in the animation data needed for this experiment, so a license was obtained with an online animation video software and applied to practical utilization of the system within an art university. First, data preprocessing is performed on an animation video library using predicted feature coefficients substituted into a classification regression tree algorithm. As previously mentioned in the section, the squared error is the loss function in this experiment. The media art teaching model is trained using the animation video data preprocessed above, and the training outcomes are displayed in the following Fig. 4.

As the resulting graph illustrates, in the early stages of training, the loss error rapidly reduces, and once the iteration round epoch surpasses 20, the function's decreasing trend is moderately delayed. Compared to the ideal case's loss value, the experimental findings align with expectations, and the classification regression tree algorithm model's prediction error falls within allowable bounds.

Then, the epoch was evaluated more comprehensively using the hidden factor dimension, and the animation video media files' number of feature vectors directly influenced the hidden factor's output dimension size. Experimentally, 248 animation students using the animation media data system were selected. When the hidden factor dimension was raised from 4 to 14, it impacted the iteration rounds, and the results are displayed in the following Fig. 5.

The greatest RMSE value can be found using the experimental findings shown in the above figure when the dimension of the hidden factor is 4, either the Epoch number is 20 or 40, which suggests that when the dimension is small, the characterization of animated images and audio features is inadequate. The RMSE value steadily drops as the dimension rises and is at its minimum when the hidden factor's dimension is 12, after which the RMSE value increases again as the dimension increases. Therefore, it can be concluded that the system model performs best for animation features when the hidden factor's dimension is 12.

The system model's accuracy and recall were tested under various recommendations and searches to verify the feasibility of this experimental categorical regression tree algorithm. The obtained results are plotted as shown below.

A comparison of the accuracy rates in the Fig. 6 shows that the accuracy rates of the recommendations using the classification regression tree algorithm model are considerably greater than those of the standard collaborative filtering recommendations after filtering the features of the animated videos and without this method. The results of the recall rate comparison between the two different algorithms are analyzed again. As the figure illustrates, the two algorithms' recall rates progressively rise as the animation search, recommendation, and viewing lists grow. An acceptable recall is attained when the recommendation list is 45, at which point the recall of the animated video data search, recommendation, and watch using the categorical regression tree model is 4.65%, while the recall of the non-standard collaborative filtering animated video data search, recommendation and watch is about 6.31%. The comparison demonstrates the influence of recommendations after filtering by the categorical regression algorithm model is superior to the irregular collaborative filtering recommendation system.

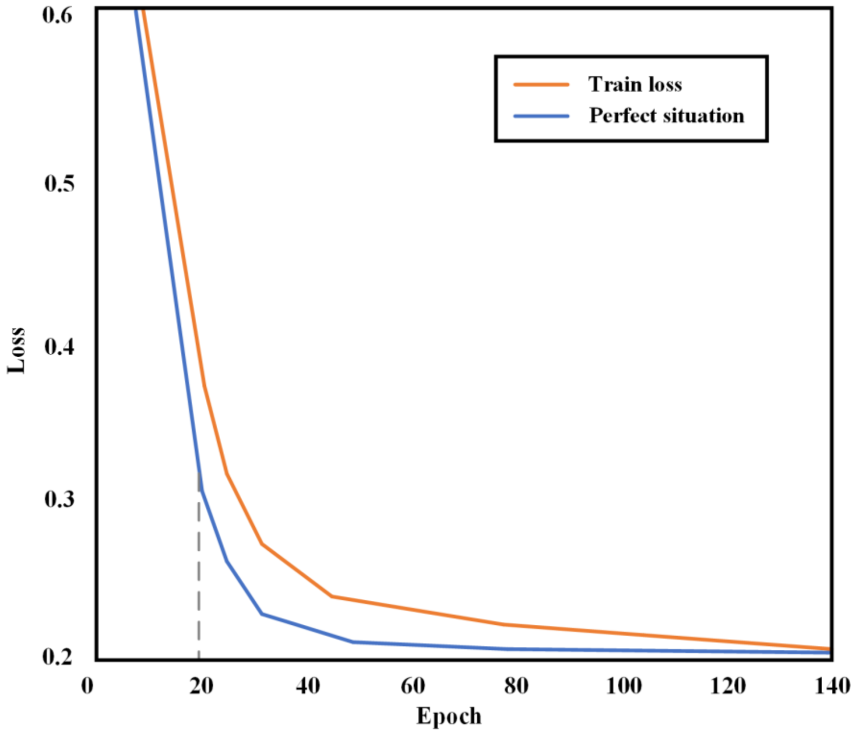

Fig. 4. The relationship between the ideal value and the loss value of the training model.

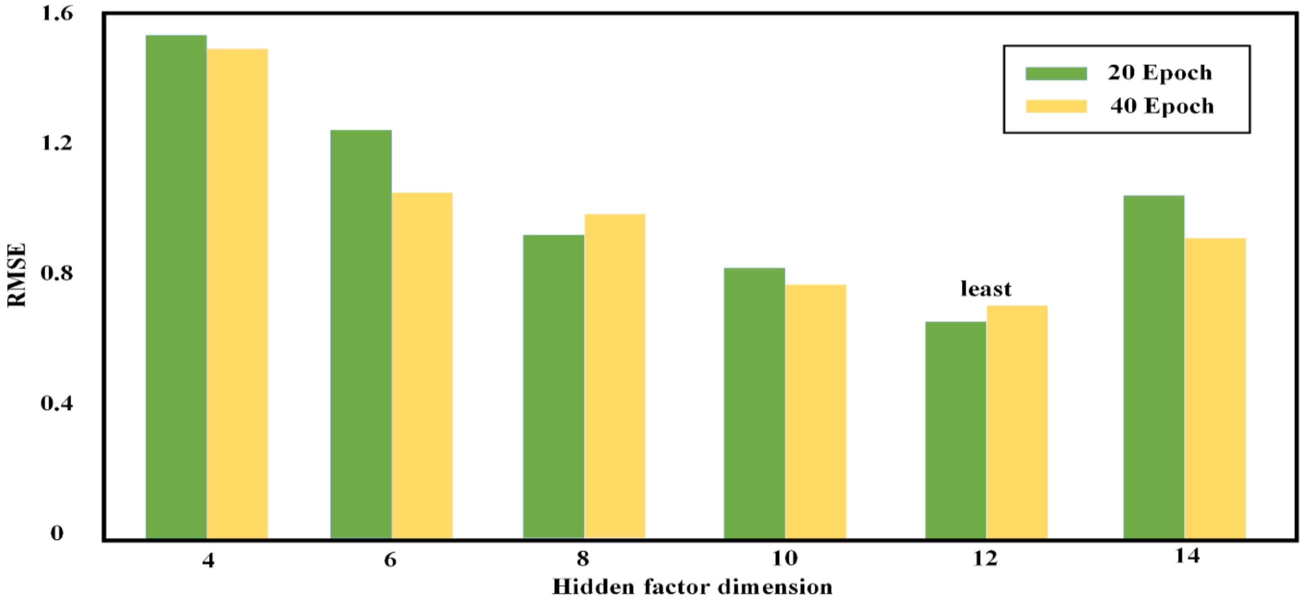

Fig. 5. RMSE of predicted scores at different k and epoch.

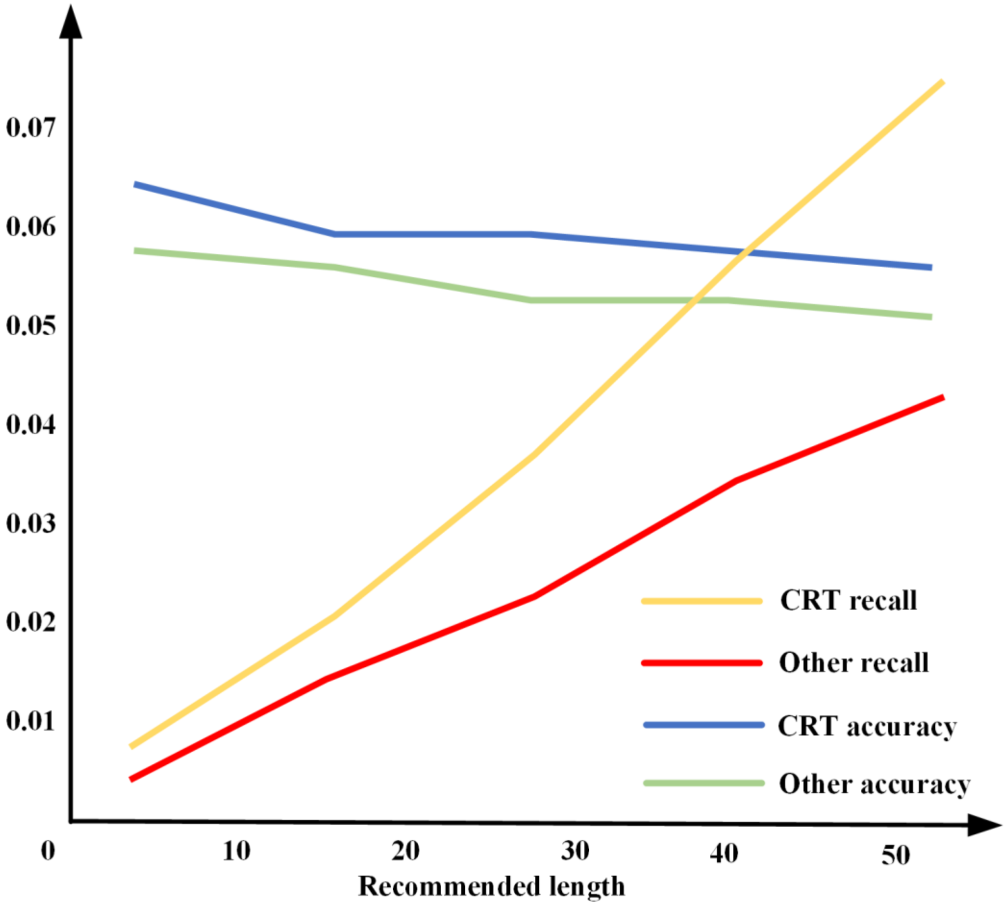

Fig. 6. Comparison plot of precision and recall for two different algorithms.

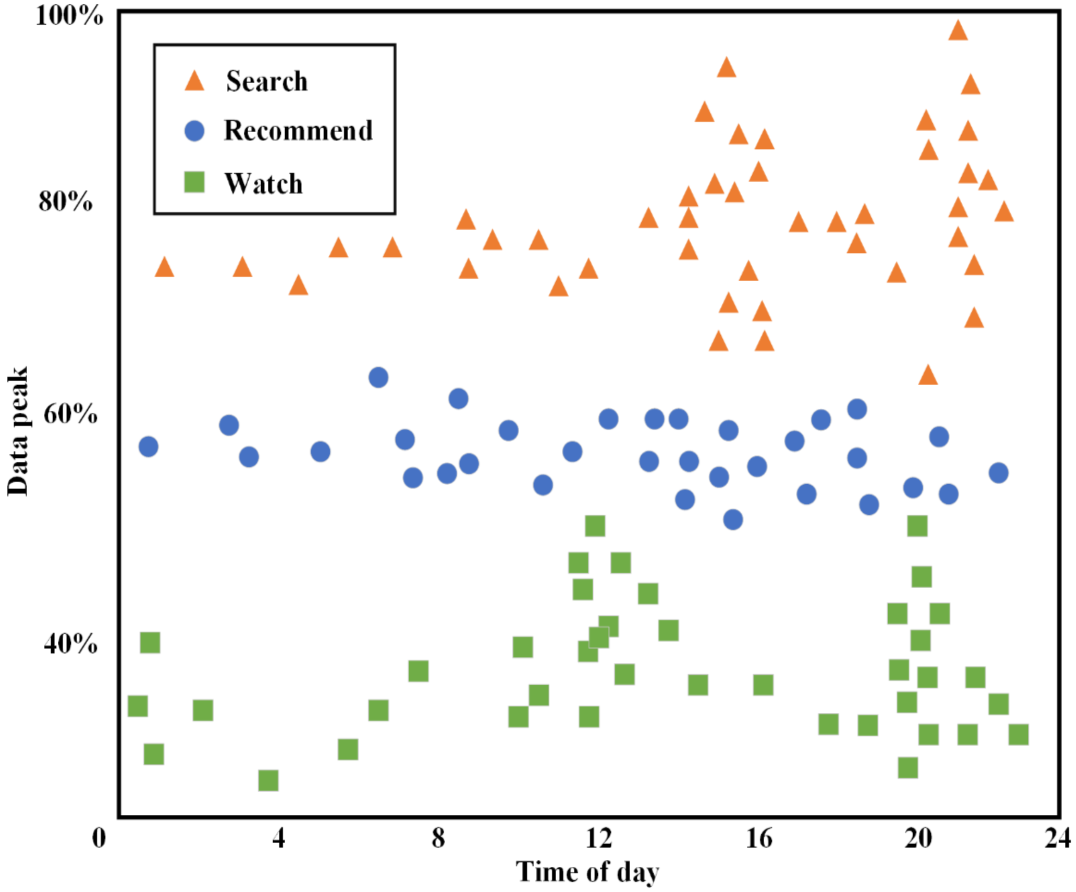

Fig. 7. Graph of peak data searched, pushed, and watched throughout the day.

The animated video data in the system has three-dimensional features. The data is dimensionally reduced to represent the database using low-dimensional data to optimize management. As shown in the Fig. 7 above, the low-dimensional data can accurately reflect the results and has no redundant features, making it faster and easier to calculate search, recommendation, and viewing results for the low-latitude data.

The above figure depicts the data peaks of the animation students searching, pushing, and watching animations during the entire day. The recommendation data peaks of the college students during the day are kept within a reasonable range without abnormal peaks and underestimations. This suggests the experiment's data system is stable and not overly resource-intensive when computing and producing recommendation results, which meets the requirements of faculty and student users. There will be two data peaks during the search, at 15:00 and 21:00. Because these two times correspond to the most frequent demands of students for entertainment and classes, this essay speculates that there might be such search peaks. The average data of the recommendation system indicates that the system makes stable recommendations at each time slot. The viewing behavior peaks at 12:00 and 20:00, which is caused by the analysis that students have the behavior habit of watching animation during lunch break and evening break time. The stability of the peak value of daytime recommendation data indicates that the system can continuously and accurately provide recommendation services to users without excessive resource occupation. The average recommendation data indicates that the system can maintain stable recommendation performance at different time periods. Through classroom testing of animation teaching, it was found that students have improved in painting, directing skills, animation scope, and animation appreciation, proving the effectiveness of the system in teaching.

After implementing the animation media art teaching system based on big data integration technology for seventy days, college students' ability in related majors was examined through animation teaching classroom tests. Fig. 8 below shows that the animation students have improved their drawing and directing skills, their scope of animation, and their appreciation of animation through the system.

The results were used for a while. The feedback from the teachers and students of the animation majors in the universities involved in the experiment was acquired using a survey. Fig. 9 below displays the results.

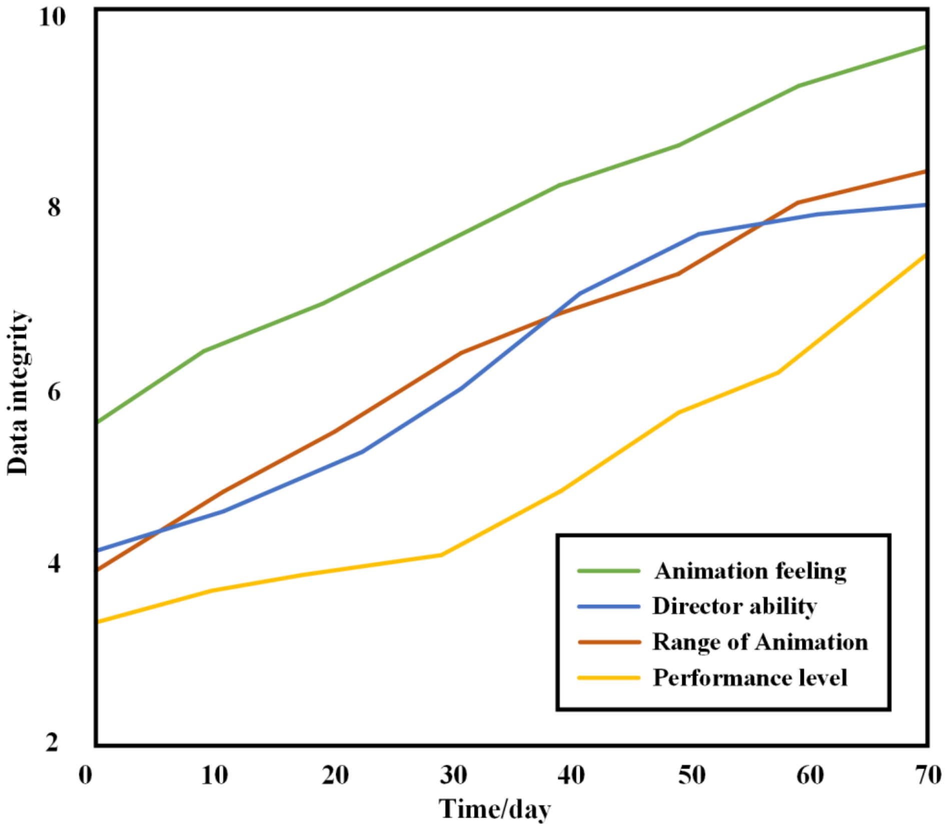

Fig. 8. The relationship between students' animation scores and days under classification regression tree model data mining.

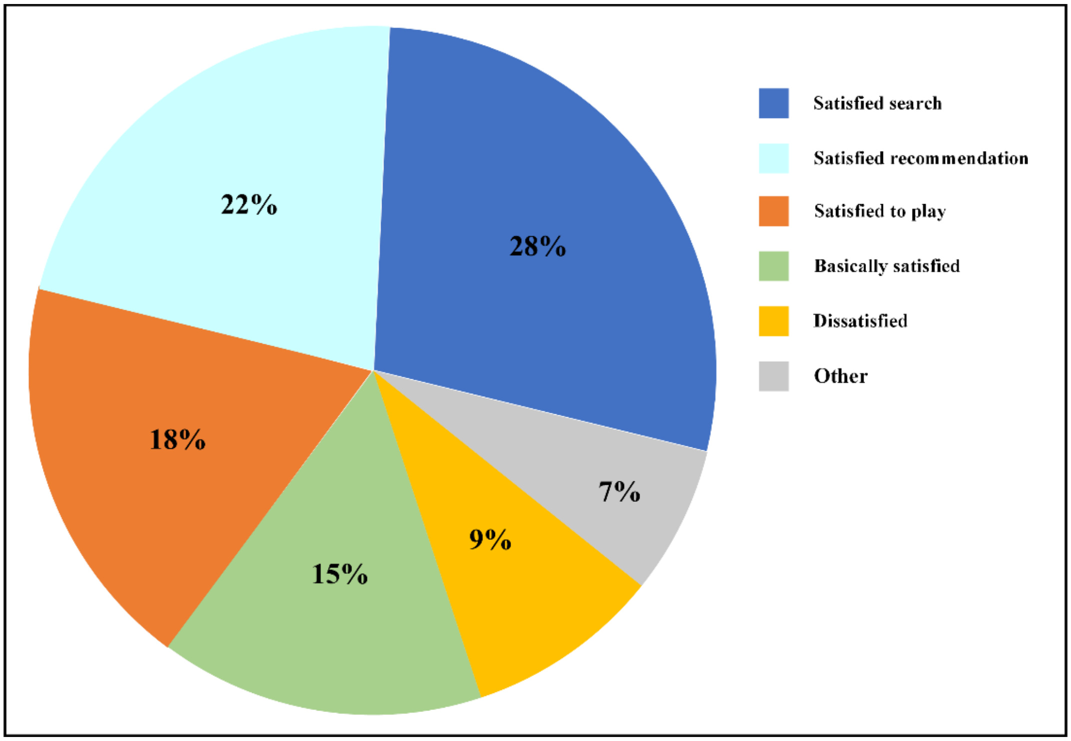

Fig. 9. The results of the teacher and student satisfaction survey of the animation media art teaching system.

V. RESULTS AND DISCUSSION

After a series of experiments and practices, the animation media art teaching system based on big data fusion technology has shown significant results. Firstly, by substituting the predicted feature coefficients of the classification regression tree algorithm into the animation video library for data preprocessing, the system can accurately extract and characterize the features of animation data, providing a high-quality dataset for subsequent teaching model training. During the training process, the loss error rapidly decreases and tends to stabilize after a certain iteration period, indicating that the model has a good fitting effect on the data and the prediction error is within an acceptable range.

When evaluating the impact of hidden factor dimensions on model performance, the experiment found that the system performed best when the hidden factor dimension was 12. At this point, the model is able to effectively extract features from animated videos and performs well in search, recommendation, and viewing. This discovery is of great significance for optimizing model structure and improving system performance.

Compared with traditional collaborative filtering recommendation systems, recommendation systems based on classification regression tree algorithms exhibit advantages in accuracy and recall. Especially in the search, recommendation, and viewing of animation video data, the classification regression tree model can more accurately filter and recommend animation content that meets user needs, improving the usability and user experience of the system.

In addition, the system optimizes data management through dimensionality reduction techniques when processing animated video data with three-dimensional features, enabling low dimensional data to accurately reflect results and improving search, recommendation, and viewing efficiency. In practical applications, the stability and performance of the system have also been verified, meeting the needs of teachers and students.

VI. CONCLUSION

This study is based on big data fusion technology and successfully constructed an animation media art teaching system, which was applied in a practical teaching environment for 70 days. By substituting the classification regression tree algorithm for data preprocessing and model training, the system demonstrated good predictive performance with errors within the allowable range. When evaluating the impact of hidden factor dimensions on model performance, it was found that when the hidden factor dimension is 12, the system performs best on animation features. In terms of recommendation and search, the accuracy of the classification regression tree algorithm model is significantly higher than that of traditional collaborative filtering recommendation methods, and the recall rate also shows superiority. In addition, the system has optimized data management through dimensionality reduction technology, enabling low dimensional data to accurately reflect results and improving the efficiency of search, recommendation, and viewing. In practical applications, the stability and performance of the system have been verified, meeting the usage needs of teachers and students. Through classroom tests and analysis of student grades in animation teaching, it was found that the system can effectively enhance students' painting and directing skills, animation scope, and appreciation of animation. The satisfaction survey results of teachers and students also show that the system has been widely applied and praised in practical teaching.

However, in research based on big data, the quality and completeness of data are crucial. In practical applications, there may be issues such as missing, incorrect, or inconsistent data. This may lead to inaccurate or biased analysis results, thereby affecting the effectiveness of instructional design. Although big data fusion technology has achieved some successful applications in other fields, its application in animation media art teaching design is still in the exploratory stage. Therefore, there may be some uncertainty in the feasibility and stability of the technology. In order to improve data quality, future research will pay more attention to the process of data cleaning, validation, and integration. By adopting advanced data preprocessing techniques, errors and inconsistencies in the data can be identified and corrected, ensuring the accuracy of the analysis results. The system will adopt more robust data storage and backup mechanisms. Meanwhile, by introducing data auditing and monitoring mechanisms, data integrity issues can be promptly identified and addressed, ensuring data integrity and credibility.

Abstract—**Human Action Recognition and Medical Image Segmentation study presents a novel framework that leverages advanced neural network architectures to improve Medical Image Segmentation and Human Action Recognition (HAR). Gated Recurrent Units (GRU) are used in the HAR domain to efficiently capture complex temporal correlations in video sequences, yielding better accuracy, precision, recall, and F1 Score than current models. In computer vision and medical imaging, the current research environment highlights the significance of advanced techniques, especially when addressing problems like computational complexity, resilience, and noise in real-world applications. Improved medical image segmentation and human action recognition (HAR) are of growing interest. While methods such as the V-Net architecture for medical picture segmentation and Spatial Temporal Graph Convolutional Networks (ST-GCNs) for HAR have shown promise, they are constrained by things like processing requirement and noise sensitivity. The suggested methods highlight the necessity of sophisticated neural network topologies and optimisation techniques for medical picture segmentation and HAR, with further study focusing on transfer learning and attention processes. A Python tool has been implemented to perform min-max normalization, utilize GRU for human action recognition, employ V-net for medical image segmentation, and optimize with the Adam optimizer, with performance evaluation metrics integrated for comprehensive analysis. This study provides an optimised GRU network strategy for Human Action Recognition with 92% accuracy, and a V-Net-based method for Medical Image Segmentation with 88% Intersection over Union and 92% Dice Coefficient.**

Keywords—Human action recognition; medical image segmentation; grated rectifier unit; V-net architecture; neural network

I. Introduction

In the fields of computer vision and artificial intelligence, human action recognition concentrates on creating systems and techniques that can automatically recognize and comprehend human actions from video footage [1] [2]. Applications such as surveillance, augmented reality, healthcare, human-computer interaction, and sports analysis depend heavily on this form of technology [3]. The main goal is to make it possible for robots to comprehend human behaviour and react accordingly, promoting more logical and instinctive interactions between people and technology. In order to recognize human actions, motion patterns, postures, and gestures made by people in a video sequence must be examined and deciphered. This frequently entails the identification and tracking of important bodily components, such as limbs and joints, as well as the extraction of pertinent characteristics that are indicative of certain movements [4]. The intricacies of the temporal and spatial dynamics of human behaviours may be captured and learned through the use of methods such as machine learning, especially deep learning. The heterogeneity in human motions across various people, contexts, and viewing situations is one of the main issues in human action recognition [5]. To be useful in a variety of real-world situations, robust techniques need to be able to generalize their learning to account for these variances. Large datasets including labelled action sequences are frequently used by researchers to train algorithms that can accurately identify a broad variety of activities.

Human action recognition may be done primarily using two methods: 2D-based and 3D-based. 2D-based techniques only take into account spatial information when recognizing actions; all other information is taken from individual video frames [6]. However, by examining the motion sequences over a number of frames, 3D-based techniques make use of both temporal and spatial information. Enhancing identification accuracy and capturing the dynamic character of actions are the main benefits of the latter technique [7]. Recognition of human actions has many real-world uses. It improves safety protocols in video surveillance systems by automatically identifying suspicious or unusual activity [8]. It can help with diagnosis and rehabilitation in the medical field by tracking and evaluating patient activities. It aids coaches and analysts in sports analysis by enabling them to assess the performance of participants and plan more skillfully. Furthermore, it makes it possible for machines to react to gestures and orders from humans, resulting in natural and straightforward user interfaces for human-computer interaction [9]. With the use of increasingly complex algorithms, better sensor innovations, and increased processing power, human action recognition keeps developing as technology progresses. Human action recognition is an important aspect in the creation of artificially intelligent machines that better comprehend and interact with the natural world. Ongoing research in this topic tries to solve issues relating to immediate analysis, scalability, and reliability [10] [11] [12].

A crucial area of study in the larger study of health care imaging is medical image segmentation, which focuses on identifying and separating certain structures or areas of interest from medical pictures. To enable a more thorough examination of different tissues, organs, or structures, this technique entails dividing a picture into meaningful and functionally relevant portions [13]. Partitioning medical images is essential for planning treatments, making diagnoses, and tracking the course of illnesses. Medical image segmentation's main goal is to give precise and accurate delineation of diseased areas or anatomical features in pictures [14]. Peptide emission tomography (PET), MRI, ultrasound, and CT are among the imaging modalities that use this technique. The creation of strong segmentation algorithms is essential for effective clinical assessments since every technique has different obstacles, such as variations in contrast, resolution, and noise [15]. The intrinsic complexity and diversity of human anatomy is one of the primary obstacles in separating medical images. The size, shape, and design of organs or other structures may vary throughout people, and diseased states may make the segmentation process even more difficult [16]. Deep learning computations, machine learning, and sophisticated processing of images approaches are used by investigators as well as practitioners to solve these issues [17]. Particularly with regard to recognizing complex patterns in medical pictures and learning centralized characteristics, deep learning has proven remarkably effective. Medical separation of images has several uses and affects different facets of health care.

Radiologists and medical professionals can more precisely detect and measure anomalies, such as tumours, lesions, or irregularities in organs, with the use of segmentation [18]. Proper segmentation is essential to target specific areas with minimal harm to surrounding healthy tissues during treatment planning, particularly in radiation treatments and surgery. Furthermore, longitudinal studies, which need medical image segmentation to follow therapy response and illness development over time, depend on it [19]. From conventional, rule-based techniques to more advanced, data-driven processes, medical imaging segmentation has evolved throughout time. Convolutional neural networks (CNNs) and other deep learning topologies are examples of machine learning systems that have demonstrated significant potential in automating and enhancing the accuracy of segmentation jobs [20]. Moreover, the use of artificial intelligence into medical picture segmentation not only improves productivity but also creates opportunities for customized treatment plans and personalized medication. Medical picture segmentation research is still ongoing, with particular issues being addressed include managing big datasets, guaranteeing robustness across different patient groups, and enhancing real-time processing capabilities [21]. Medical image segmentation continues to be essential to the creation of cutting-edge medical and diagnostic devices as technological develops, improving the results for patients and care.

The key contributions of this study are as follows:

- The research contributes a robust framework for Human Action Recognition by utilising Gated Recurrent Units (GRUs) with an advanced gating mechanism. This results in superior accuracy, precision, recall, and F1 Score when compared to existing models.
- The study offers an effective V-Net architecture-based approach for medical image segmentation. The model achieves impressive Dice Coefficient, Intersection over Union (IoU), recall, and F1 Score, pushing the state-of-the-art in precise structure delineation. It also performs exceptionally well in capturing spatial dependencies and complex characteristics in volumetric medical pictures.
- The integration of Min-Max normalization ensures equitable feature contributions, particularly valuable when dealing with datasets containing features of varying scales. Furthermore, by applying the Adam optimizer, the Human Action Recognition and Medical Image Segmentation models perform better, exhibiting flexibility in the face of different gradients and the ability to process big datasets with high-dimensional feature spaces.
- The study highlights the investigation of attention mechanisms in Human Action Recognition and the use of transfer learning and new loss functions in Medical Image Segmentation to further improve model performance and generalisation across various datasets. These valuable insights could lead to further research endeavours.

The research began with a preliminary study of the literature review and research gasps, which are presented in Section II. The research was performed according to the proposed research methodology and is presented in Section III. The results of the study are presented and discussed in Section IV. Finally, the conclusions and limitations are presented in Section V.

II. Related Works

The capacity of skeleton-based action detection to record human body motions using 3D skeletal joint data has attracted a lot of attention in the field of computer vision. One effective approach for simulating the spatiotemporal relationships in such data is the Spatial Temporal Graph Convolutional Network (ST-GCN) [22]. An extensive investigation of the use of ST-GCNs for skeleton-based action recognition is presented in this research. The suggested model makes use of both temporal and spatial graph convolutions to efficiently represent the complex interactions that develop between skeletal joints over time, allowing for reliable action identification in a variety of contexts. Although ST-GCNs have proven to be useful, one significant limitation is their susceptibility to noise and errors in skeletal joint data. The quality of the input data in real-world applications might be impacted by noise from depth sensors, occlusions, or errors in joint localization. Such noise may be too much for ST-GCNs to manage, which might result in subpar performance and possibly incorrect classifications. Resolving this constraint is essential to improving the model's resilience in real-world scenarios, particularly when handling noisy or incomplete skeleton data that is frequently encountered. Prospective research avenues may concentrate on devising techniques to enhance the robustness of ST-GCNs against noisy input, guaranteeing dependable action identification under demanding circumstances.

Zhu et al. [23] research presents a novel method for action identification in video data: Hidden Two-Stream Convolutional Networks (HTSCNs). The spatial and temporal streams that make up the two-stream architectural have shown to be successful in gathering both appearance and motion data. Nevertheless, the efficient fusion of both streams to extract distinct characteristics is frequently a difficulty for classic two-stream networks. A hidden fusion mechanism is added to HTSCNs, enabling more contextually aware and adaptable fusing of temporal and spatial data. The technique that has been suggested performs better at identifying intricate activities by utilizing the complimentary data from both sources. Although HTSCNs provide improvements in the fusion of temporal and spatial data, the hidden fusion mechanism's added computing complexity may be a disadvantage. During training and inference, the extra layers or procedures added for adaptive fusion may require more processing power. This may restrict the framework's usefulness in situations when resources are few or real-time. When implementing HTSCNs in environments with limited computing resources, it is important to balance the enhanced fusion capacities with the effectiveness of computation. In order to preserve the advantages of the concealed fusion process while reducing the computational cost and guaranteeing wider usage and accessibility of the suggested technique, future research might investigate optimizations or other approaches.

The sophisticated movement detection system presented in this study makes use of Long-Term Recurrent Convolution Networks (LTRCNs) [24], a hybrid design that combines the advantages of convolutional and recurrent neural networks. In interacting with computers, gesture recognition is essential, and the suggested LTRCN model tackles the difficulties in capturing the temporal and spatial connections in gesture sequences. The model achieves advanced performance in recognizing a selection of complicated gestures by utilizing convolutional methods to capture spatial data and recurrent layers to include long-term memory. The efficacy of the LTRCN is demonstrated by its positive outcomes in a variety of situations in real life, such as recognizing signs and human-computer interface exchanges. The LTRCN's higher processing requirements, especially during training, might be a disadvantage considering its outstanding performance. Higher resource needs and longer training periods may result from the incorporation of repetitive layers, which describe temporal relationships across lengthy sequences. This might provide problems in instances where distribution on devices with limited resources or real-time processing are critical. For real-world use, it is important to address the computing cost while maintaining the accuracy of the model. To increase the viability of implementing the LTRCN in actual, limited resources contexts, future research might concentrate on improving training efficiency, investigating model compression approaches, or creating hardware-accelerated systems.

The unique ViT-V-Net method for unsupervised dimensional imaging identification is presented in this research. It makes use of the Vision Transformer (ViT) structure [25]. Optimizing the combination of pictures from distinct sources or time periods is a crucial job in many clinical applications such as medical image registrations. In order to extract strong features for precise registration without requiring labelled training data, ViT-V-Net makes use of the self-attention mechanism built into ViT to capture long-range relationships in volumetric data. This approach has the potential to improve medical image assessment and diagnosis because of its better effectiveness in regarding accuracy and adaptability. The potential disadvantage of ViT-V-Net is its computational cost, even if it offers an attractive option for unsupervised volumetric medical picture registration. This is because Vision Transformer designs are complicated. The volumetric medical data analyzing requires managing huge input sizes, which can result in higher memory and computing needs. ViTs are notorious for being parameter-intensive. Specifically in actual time or limited resources clinical situations, the scalability of ViT-V-Net for big health data sets and the effectiveness during inferences are issues that require careful study. In order to assure ViT-V-Net's effectiveness for healthcare contexts with diverse computing resources, future study may concentrate on optimizing the computational effectiveness of the system and investigating acceleration using hardware or model compression approaches.

Liver and tumour segmentation on computed tomography (CT) images are addressed by this study, which presents a unique technique to medical picture segmentation. Using a 2.5D Fully Convolutional Neural Networks (FCNN) architecture [26], the suggested approach makes use of boundary loss. Utilizing both spatial and volumetric contexts to enhance segmentation accuracy, the 2.5D method integrates 2D and 3D data. The model's capacity to accurately define object borders is improved by the addition of boundary loss, which is important for medical imaging applications. Results from experiments using CT datasets reveal how well the suggested method works to segment liver and tumour structures with high accuracy and detail, indicating its potential to improve clinical diagnostics. The Boundary Loss-Based 2.5D FCNN technique has a potential downside in that it is sensitive to fluctuations in data quality and imaging artifacts that are frequently found in medical pictures, while its optimistic effectiveness in segmenting. Noise, artifacts, and inefficiencies in CT scans might compromise the model's resilience and ability to generalize to a variety of datasets. It is imperative to tackle this obstacle in order to implement the suggested approach in various medical imaging contexts. In order to strengthen the algorithm's dependability in practical healthcare settings, further research should examine ways for enhancing the model's resistance to noise and artifacts, such as using data augmentation tactics or creating sophisticated preparation approaches.

Y. Chen et al. [27] research, a conditional random field (CRF) and deep learning are used to propose an effective two-step method for liver and tumour segmentation on abdominal CT images. In the first stage, the liver and tumour areas are coarsely delineated with the use of a deep learning algorithm for initial segmentation. The segmentation is then further refined by enhancing the consistency of space and integrating historical data using a conditional random field. The suggested technique successfully and efficiently segments the data, as shown by the abdominal CT datasets. The aforementioned two-step procedure exhibits the potential of CRF to improve precision in medical image analysis by utilizing not just the structured modelling skills of CRF for enhanced segmentation results, but also the capability of deep computing for extracting features. The conditionally random field in the refining stage adds additional processing complexity, which might be a disadvantage even though the two-step strategy appears promising. The effectiveness of the method for segmentation may be impacted by the increased computing cost, especially in situations when immediate analysis is essential, such during critical circumstances or surgical procedures. For real-world implementation, it is crucial to strike a compromise between increased segmentation accuracy and computing efficiency. Subsequent investigations might examine optimizations, parallelization tactics, or substitute improvement methods to reduce processing requirements while preserving the superior segmentation attained via the integration of deep learning and CRF methodology.

The new methods for addressing different computer vision and imaging-related problems are presented in these publications. While conceding their susceptibility to noise, the first study highlights the efficiency of skeleton-based action identification utilizing Spatial Temporal Graph Convolutional Networks (ST-GCNs). In order to recognize actions, the second one presents Hidden Two-Stream Convolutional Networks (HTSCNs), which exhibit better performance but acknowledge higher computational cost. The third paper investigates gesture recognition using Long-Term Recurrent Convolution Networks (LTRCNs), which show promise but also have greater processing costs. The fourth study looks into volumetric medical image registration without supervision using Vision Transformer (ViT). It performs better but raises concerns about computational complexity. Lastly, a two-step conditional random field and deep learning approach to liver and tumour segmentation on CT images demonstrates effectiveness despite a greater processing cost. Overall, these studies provide valuable insights into advanced techniques for diverse applications, but they also highlight the on-going challenge of finding a compromise between computer performance and efficiency.

The present research environment emphasizes the importance of sophisticated techniques in computer vision and medical imaging, particularly when dealing with issues like noise, computational complexity, and robustness in real-world applications. There is an increasing interest in enhancing human action recognition (HAR) and medical image segmentation. While approaches like Spatial Temporal Graph Convolutional Networks (ST-GCNs) for HAR and the V-Net architecture for medical picture segmentation have showed promise, they are limited by factors such as noise sensitivity and processing need. These constraints limit their efficacy in real-world applications with noisy data and limited processing resources [23].

As a result of this, the proposed method's overarching problem is to create a framework that uses advanced neural network architectures, such as Gated Recurrent Units (GRU) for HAR and V-Net for medical image segmentation, to improve the robustness, accuracy, and efficiency of these tasks in real-world settings. This involves minimizing the impact of noise in skeletal joint data for HAR, controlling the computational complexity of fusion mechanisms in HAR models such as Hidden Two-Stream Convolutional Networks (HTSCNs), handling processing demands in Long-Term Recurrent Convolution Networks (LTRCNs) for gesture recognition, maximizing computational efficiency in Vision Transformer (ViT) for volumetric medical image registration, and enhancing resilience to noise and artifacts in liver and tumor segmentation on CT images through the use of 2.5D Fully Convolutional Neural Networks (FCNN) and conditional random field (CRF) techniques [27] [25].

III. Proposed Mechanism of HAR and Image Segmentation

The proposed approach integrates min-max normalization as a preprocessing step to standardize input data, ensuring consistent scales for subsequent tasks. In the domain of Human Action Recognition, Gated Recurrent Units (GRU) is employed to capture temporal dependencies, enabling effective modelling of sequential human actions. For Medical Image Segmentation, the proposed method utilizes the V-net architecture, a 3D convolutional neural network designed for precise delineation of structures in medical images. The optimization process is facilitated by the Adam optimizer, enhancing convergence during model training. Performance evaluation involves metrics such as accuracy, precision, recall, and F1-score to comprehensively assess the effectiveness of the proposed approach in achieving accurate and robust results in both human action recognition and medical image segmentation tasks. Fig. 1 illustrates the workflow of the proposed mechanism.

The proposed solution introduces novel advancements in both Human Action Recognition (HAR) and Medical Image Segmentation by leveraging Gated Recurrent Units (GRU) and the V-Net architecture, respectively. In contrast to existing frameworks like Spatial Temporal Graph Convolutional Networks (ST-GCNs) for HAR, the utilization of GRUs enables efficient capture of complex temporal correlations in video sequences, addressing long-range dependencies and the vanishing gradient problem. This enhances the model's accuracy and reliability in action detection tasks. Similarly, in Medical Image Segmentation, the V-Net architecture offers superior precision in identifying structures of interest compared to traditional convolutional neural networks (CNNs) or Fully Convolutional Neural Networks (FCNNs). By integrating these advanced techniques, the proposed solution provides a comprehensive approach to improving performance and resilience in both HAR and Medical Image Segmentation tasks, offering significant advancements over existing methodologies.

Performance Evaluation

Fig. 1. Mechanism of human action recognition and medical image segmentation.

A. Min-Max Normalization

A data preparation method called min-max normalization is used to rescale numerical characteristics within a certain range, usually between 0 and 1. This technique guarantees that every feature contributes equally to the model training process, which makes it very helpful when working with datasets that contain features of varying sizes. For Min-Max normalization, (1) is provided:

$$X_{Norm} = \frac{X_{max}-X_{min}}{X_{min}} \tag{1}$$

Where, X_{Norm} is the normalized value of the feature, X is the raw data, X_{min} is the minimum value of the feature in dataset and X_{max} is the maximum value of the feature in the dataset.

B. Human Action Recognition with GRU

A computer vision problem known as Human Action Recognition (HAR) entails recognizing and categorizing human actions from video footage. It may be used in many different domains, including as healthcare, human-computer interaction, and surveillance. Recurrent neural networks (RNNs), of which Gated Recurrent Units (GRUs) are a particular kind of RNN architecture, are a common method for handling HAR. One sort of recurrent neural network that is particularly good at identifying sequential relationships in data is the Gated Recurrent Unit (GRU). GRUs are equipped with a more advanced gating mechanism than typical RNNs, which helps them deal with long-range dependencies and solve the vanishing gradient issue [28]. For processing sequential input, such as video frames, in the framework of human action detection, it makes GRUs particularly effective. The input to network infrastructure in the context of HAR with GRU is a series of video frames that depict a human activity. Every frame is considered a temporal step, and temporal relationships between successive frames are captured by the GRU as it analyses each frame individually. The primary benefit of employing GRUs is their capacity to preserve a hidden state that contains data from earlier frames, allowing the network to pick up on patterns in the temporal progression of activities. The input layer, the GRU layer, and the output layer are the three primary parts of the framework of a GRU-based HAR framework.

The sequential method video frames are sent into the input layer, and the GRU layer analyses those images while preserving a hidden state that contains temporal information. The final prediction, which indicates the acknowledged human action, is produced by the output layer. Backpropagation through time (BPTT) is used to modify the weights of the GRU network as it learns from labelled video sequences input into the model. Reducing the discrepancy between the actual truth classifications and the expected behaviours is the aim. Through this approach, the temporal dynamics of different human behaviours may be captured by the GRU. Researchers frequently use strategies like data augmentation, transfer learning, and attention processes to improve the efficiency of HAR with GRU. The technique of transfer learning entails pretraining the framework on a big dataset and optimizing it for the particular HAR task, whereas data augmentation is performing random modifications to the input data to improve the variety of training samples. By aiding the model in concentrating on pertinent segments of the input sequence, attention mechanisms enhance the model's capacity to identify critical details for action detection. In summary, Gated Recurrent Units are used in Human Action Recognition using GRU to identify temporal connections in sequential video data. This framework is a potent tool for jobs requiring the interpretation of dynamic activities from video streams because of its GRU-based design, which allows it to learn and recognize patterns in the temporal development of human behaviours. Fig. 2 depicts GRU architecture.

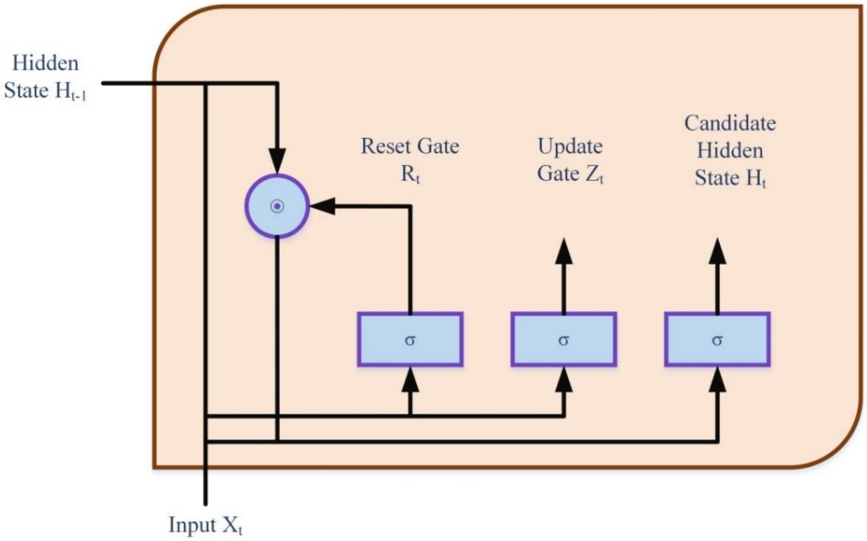

Fig. 2. GRU Architecture.

C. Sequence Modelling with GRU

An RNN type called a GRU is made specifically to identify and represent dependencies in sequential data. They work especially well with long-range interdependence, which is a critical component in comprehending how people behave over time. The update gate, reset gate, and hidden state are a GRU's essential parts. Here is how the reset gate r_t and update gate z_t are computed in (2) and (3):

$$z_t = \sigma(W_z * [h_{t-1}, x_t]) \quad (2)$$

$$r_t = \sigma(W_r * [h_{t-1}, x_t]) \quad (3)$$

Where, the input at the current time step is x_t, while the hidden state at the previous time step is h_{t-1}. The sigmoid activation function is σ.

1) Candidate hidden state calculation: The reset gate r_t and the current input x_t are used to calculate the candidate hidden state $\tilde{h}_t$ is expressed i (4):

$$\tilde{h}_t = \tan h(W_h * [r_t \odot h_{t-1}, x_t]) \quad (4)$$

Here, ⊙ denotes element-wise multiplication.

2) Update hidden state: The candidate hidden state $\tilde{h}_t$, the preceding hidden state h_{t-1}, and the update gate z_t are used to update the hidden state h_t is expressed in (5):

$$h_t = (1 - z_t) \odot h_{t-1} + z_t \odot \tilde{h}_t \quad (5)$$

3) Action recognition using GRU: A video clip is supplied frame by frame into the GRU model for HAR. Action categorization uses the final hidden state h_T obtained by analyzing the whole sequence. The one way to accomplish this is to transmit h_T across a fully linked layer and then a softmax activation function in (6):

$$Action\ Score = softmax(W_{out} * h_T + b_{out}) \quad (6)$$

Where, W_{out} and b_{out} represent the weight matrix and bias vector of the output layer, respectively. When using GRUs for Human Action Recognition, video sequences are processed using a recurrent neural network. The GRU records temporal relationships, and action categorization is done using the final hidden state. Optimizing the parameters to minimize a selected loss function is the process of training the algorithm.

D. Medical Image Segmentation with V-net

V-Net Medical Image Segmentation is an advanced method that uses deep learning techniques to identify and categorize structures of interest in medical pictures. Three-dimensional medical picture segmentation tasks are a good fit for V-Net, an extension of the U-Net architecture that is particularly made for volumetric data. In order to achieve precise and significant segmentation in the field of medical imaging, V-Net's primary strength is its capacity to capture spatial dependencies and minute features in medical pictures. In the V-Net architecture [29], structured characteristics are captured by the encoder using a sequence of 3D convolutional layers, and the segmented output is reconstructed by the decoder using 3D deconvolutional layers. Skip connections, which link matching encoding and decoding layers and aid in the retention of spatial information, define the architecture. This capability is especially useful for applications involving the segmentation of medical images where accurate localization of structures is crucial. Reversed linear unit (ReLU) activation functions, batch normalization, and three-dimensional convolutions are the processing steps that the input medical picture passes through along the encoding path. With the help of these layers, which extract hierarchical characteristics at various sizes, the incoming data is richly represented. During the encoding-decoding process, the skip connections make sure that minute information are kept. Three-dimensional deconvolutions are used in the decoding path to up sample feature maps. Each decoding layer also includes batch normalization, ReLU activation, and three-dimensional convolutions, just like in the encoding path. In order to concatenate the high-resolution feature maps from the encoding path and facilitate the reconstruction of the segmented output with better localization accuracy, skip connections are essential during the decoding phase.

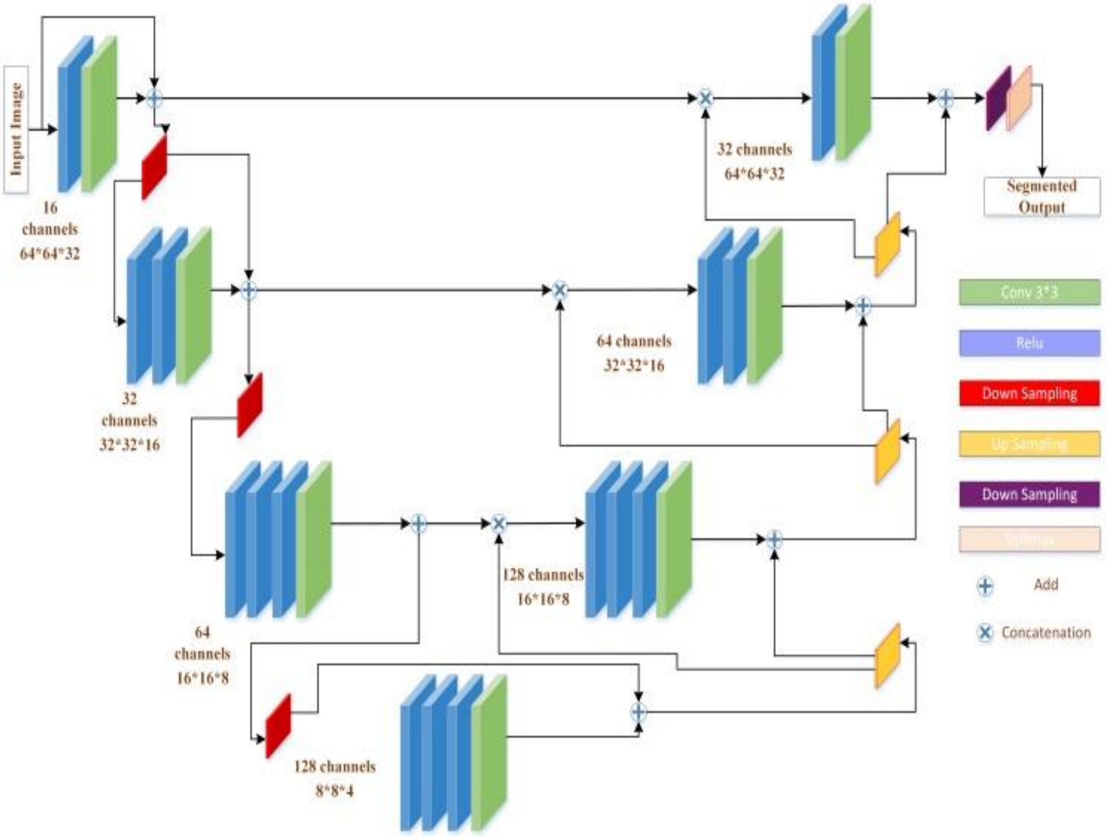

Fig. 3. V-Net architecture.

The segmentation map is usually generated via a 1x1x1 convolution in the last layer of the V-Net. To get probability scores for each class, a softmax activation function is frequently used. This allows the model to classify each voxel in the picture to the correct structure or class. Depending on the particular segmentation job, a loss function such as cross-entropy loss or dice coefficient loss may be selected during training. The V-Net model is trained on annotated medical picture datasets with ground truth segmentation masks during the training phase. The optimization method, usually Adam or SGD, minimizes the selected loss function by iteratively adjusting the model's parameters. Furthermore, methods like class-weighted loss or data augmentation may be used to resolve class imbalance, which is common in medical picture segmentation tasks. Using previously unknown medical pictures, the trained V-Net is utilized during the inference phase to create segmentation maps that identify and highlight structures of interest. To improve the segmentation result, post-processing techniques like thresholding might be used. All things considered, V-Net is a reliable method for medical picture segmentation that advances the area of medical imaging's therapeutic and diagnostic applications. Specifically created for volumetric medical picture segmentation, V-Net is an expansion of the U-Net architecture. Fig. 3 depicts V-Net Architecture and its design is made up of skip connections in an encoder-decoder configuration. Mathematically, batch normalization, ReLU activation functions, and a sequence of 3D convolutions are used in the encoding process is expressed in (7):

$$f_{encoder} = RELU\left(BatchNorm\left(Conv3D(x)\right)\right) \tag{7}$$

Here, $f_{encoder}$ represents the feature map, x is the input image, $Conv3D$ denotes the 3D convolution operation, and $BatchNorm$ represents batch normalization. The V-Net design relies heavily on skip connections, which let the model maintain fine-grained information during the encoding-decoding procedure. The skip link may be expressed mathematically as follows in (8):

$$Skip = Concatenate(x, f_{enc}) \tag{8}$$

Here, $Concatenate$ merges the input image x with the feature map f_{enc}. The decoding path entails processing by using decoding layers and more samples the feature maps using 3D deconvolutions in (9):

$$f_{decoder} = ReLU\left(BatchNorm\left(Conv3DTanspose(Skip)\right)\right) \tag{9}$$

Here, $Conv3DTanspose$ represents the 3D deconvolution operation. The segmentation map is generated by the last layer using a softmax activation function and a 1x1x1 convolution in (10):

$$SegMap = Softmax\left(Conv1 \times 1 \times 1(f_{dec})\right) \tag{10}$$

For every class, probability scores are provided by the softmax activation. The segmentation task influences the loss function selection. Frequently employed in medical picture segmentation, dice coefficient loss is described as follows in (11):

$$Dice = \frac{2 \times Intersection(G,S)}{Union(G,S)} \tag{11}$$

Here, G is the ground truth segmentation mask, and S is the predicted segmentation mask. For precise medical picture segmentation, V-Net combines encoding, decoding, skip connections, and a softmax output layer. During inference, the model is applied to unseen pictures for segmentation, with optional post-processing steps for improvement. Training entails optimizing parameters using a chosen loss function.

E. Adam Optimizer for HAR and Image Segmentation

1) Adam optimizer for human action recognition: The Adam optimizer is essential to the training of the neural network in Human Action Recognition (HAR). Recurrent neural networks (RNNs), such as the Gated Recurrent Unit (GRU), are frequently used in sequential data processing. With HAR, temporal relationships in video sequences are captured, and training over a variety of action sequences is made more efficient because to Adam's adjustable learning rates. When improving the model features during training, the optimizer may constantly modify the step sizes. This is especially useful for HAR jobs, where the complexity and length of several activities might differ. The model integrates effectively, reflecting both short-term and long-term correlations in human activities, thanks to the optimizer's flexibility in responding to the diverse gradients of various acts. Smooth parameter updates are made possible by Adam's first and second moment estimations, which are exponential moving averages. These moving averages give the optimizer assistance in navigating the complex dynamics of human motions in the context of HAR, where the detection of actions depends on subtle temporal patterns. The bias correction feature in Adam also helps to maintain the stability and dependability of the training procedure by preventing unwarranted biases in parameter estimations from being introduced during the early stages of training. However, by rapidly adapting to the temporal features of actions and guaranteeing steady convergence during the optimization process, the Adam optimizer improves the training accuracy of frameworks for Human Action Recognition.

2) Adam optimizer for medical image segmentation: The flexibility and effectiveness of the Adam optimizer make it a good candidate for Medical Image Segmentation applications, such as those using topologies like V-Net, because it can handle big datasets with extremely dimensional feature spaces. Complex spatial relationships are involved in image segmentation, and Adam's adaptive learning rates help deep neural networks be trained for reliable segmentation. 3D volumetric data is processed by the architecture in V-Net-based medical picture segmentation. The optimizer [30] may separately adjust characteristics for various spatial dimensions thanks to the adaptive learning rates, which guarantees that the model accurately represents the subtleties and spatial connections present in the health-related images. Adam's exponential fluctuations facilitate the optimization process' smooth convergence, which enables the model to pick up on and adjust to intricate patterns found in medical imagery. In medical picture segmentation, where retaining accuracy in early training phases is critical for exact segmentation, Adam's bias correction is especially relevant. The optimization process is made more solid and dependable by the correction terms, which guarantee that the optimizer begins with objective estimations. For problems involving Medical Image Segmentation, where stability during training, effective convergence, and flexibility to spatial dependencies are critical, the Adam optimizer is a good fit. In addition to exponentially average movements and bias correction, the flexible learning rate technique makes the development of deep neural networks more successful in terms of producing dependable and accurate medicinal image segmentation.

Algorithm I: Adam Optimizer

```
Step 1:  Initialize the parameters of the segmentation model, including the weights and biases, and the Adam optimizer hyper parameters $(\alpha, \beta_1, \beta_2, \epsilon)$.
Step 2:  Initialize the first moment estimate $(m_t)$ and the second moment estimate $(v_t)$ to 0.
Step 3:  For each iteration $t$:
         a. Compute the gradient of the loss with respect to the segmentation model parameters $\nabla_0 Loss$.
         b. Update the first moment estimate $(m_t)$ and the second moment estimate $(v_t)$ using exponential decay:
            $m_t = \beta_1 * m_{t-1} + (1 - \beta_1) * \nabla_0 Loss$
            $v_t = \beta_2 * v_{t-1} + (1 - \beta_2) * (\nabla_0 Loss)^2$
Step 4:  Perform bias correction to account for initialization bias in the moments:
            $\widehat{m}_t = \frac{m_t}{1 - \beta_1^t}$
            $\hat{v}_t = \frac{v_t}{1 - \beta_2^t}$
Step 5:  Update the segmentation model parameters using the bias-corrected estimates and the learning rate:
            $\theta_{t+1} = \theta_t - \frac{\alpha}{\sqrt{\hat{v}_t + \epsilon}} * \widehat{m}_t$
Step 6:  Repeat the process for a specified number of iterations or until convergence.
```

Algorithm 1 describes the Adam Optimizer. These actions together form the Adam optimization algorithm in both situations, which offers a flexible and effective method of updating model parameters when training medical image segmentation and human action recognition systems. The Adam optimizer performs best in these situations when hyper parameters are adjusted and convergence is monitored.

IV. RESULTS AND DISCUSSION

A Python tool has been developed to carry out min-max normalisation, apply V-net for medical image segmentation, use GRU for human action detection, and optimise with the Adam optimizer. Performance assessment metrics have been included for thorough examination. Robust approaches are employed in the research for both model optimisation and evaluation, namely, Medical Image Segmentation using the V-Net architecture and Human Action Recognition (HAR) with

GRU networks. Min-Max normalisation rescales numerical attributes between 0 and 1 to guarantee equal feature contributions. The GRU-based HAR framework achieves noteworthy accuracy metrics of 92%, precision of 93%, recall of 91%, and an F1 Score of 92% by utilising the advanced temporal analytic capabilities of GRUs to identify sequential patterns in video data. A Dice Coefficient of 92%, Intersection over Union (IoU) of 88%, recall of 94%, and an exceptional F1 Score of 96% demonstrate the superior performance of the V-Net-based Medical Image Segmentation. Additionally, the Adam optimizer is important for improving the training efficiency of the Medical Image Segmentation and HAR models. It can handle huge datasets with high-dimensional feature spaces and adjust to different gradients in action sequences. The study results highlight how well the suggested approaches progress the fields of medical picture segmentation and HAR.

A. Performance Evaluation

1) Performance for human action recognition: For comparison, the following evaluation criteria were used: recall, F1-score, precision and accuracy. These parameters were used to assess the model. These are depicted below:

2) Accuracy: The prediction accuracy shown in (12) that is most frequently employed to assess classification performances is second hand to measure the classifier's general usefulness.

$$Accuracy = \frac{Tp' + Tn'}{Tp' + Tn' + Fp' + Fn'} \qquad (12)$$

3) Precision: The term precision is used to describe how well a group of outcomes agree with one another. Precision is usually defined as the difference between a set of outcomes and the set's arithmetic mean. It is shown in (13).

$$Precision = \frac{Tp'}{Tp' + Fn'} \qquad (13)$$

4) Recall: The purpose of recall analysis shown in (14) is to ascertain, under a certain set of assumptions, how several morals of an autonomous alterable effect a specific reliant on flexible. This procedure is applied within prearranged bounds that are dependent on single or additional input data variables.

$$Recall = \frac{Tp'}{Tp' + Fn'} \qquad (14)$$

5) F1 Score: Outcomes additional than estimate precision had better also be assessed when assessing the performance. The F1 score that is computed for this purpose evaluates the correlation among the information's expectant information and the classifier's predictions. It is shown in (15).

$$F1\ score = \frac{2Tp'}{2Tp' + Fp' + Fn'} \qquad (15)$$

6) Performance for medical image segmentation: For comparison, the following evaluation criteria were used: dice coefficient, intersection over unit (IoU), recall (14) and F1-score (15). These parameters were used to assess the model. These are depicted below:

7) Dice coefficient: The Dice Coefficient is a similarity metric for image segmentation that quantifies the overlap between the predicted and ground truth regions, calculated as twice the area of intersection divided by the total area of predicted and ground truth regions in (16).

$$Dice = \frac{2 * Area\ of\ Intersecion}{Total\ Area\ of\ Predicted + Total\ Area\ of\ Ground\ Truth} (16)$$

8) Intersection over Unit: The Intersection over Union (IoU) is a measure of the overlap between the predicted and ground truth regions in image segmentation, calculated as the area of intersection divided by the area of union in (17).

$$IoU = \frac{Area\ of\ Intersecion}{Area\ of\ Union} \qquad (17)$$

Fig. 4 shows the training accuracy of the Human Action Recognition model, which uses GRU networks for training, is a gauge of the model's effectiveness on the training dataset. It shows the proportion of cases that are properly categorised to all training samples. The training accuracy gives information about how well the model learns from the labelled data as repeatedly changes its parameters to minimise the loss function. Testing accuracy, on the other hand, evaluates how well the model generalises to fresh, untested data. It is computed by testing the model on an independent testing dataset that was not utilised for training. In order to enable generalisation to a variety of instances outside of the training data, a successful model usually has high training accuracy, which indicates effective learning from the training set, while retaining a comparable or slightly lower testing accuracy.

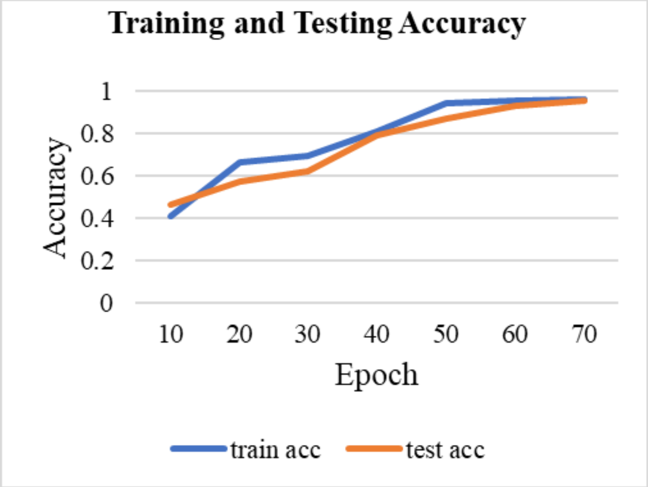

Fig. 4. Training and testing accuracy – GRU.

In order to assess the overall performance of the model and prevent overfitting or underfitting problems, it is imperative to keep an eye on both training and testing accuracy.

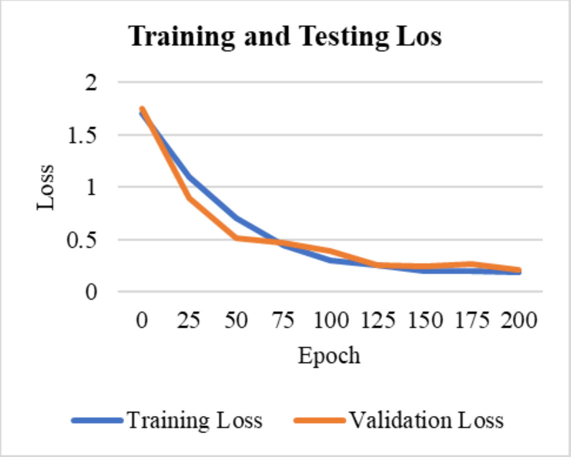

Fig. 5. Training and testing loss – GRU.

Fig. 5 shows the evaluation of a model's performance at various stages is largely dependent on the training and testing losses in the context of GRU networks and Human Action Recognition. The total error between the model's predictions and the ground truth labels on the training dataset is represented by the training loss. The goal is to minimise this loss while the model goes through training cycles by modifying the network's parameters. In contrast, testing loss is calculated using a different dataset that was not used for training the model. It functions as a crucial parameter for assessing how well the model generalises to fresh, untested data. To provide robustness and avoid overfitting, an efficient model has a comparable or slightly greater testing loss while exhibiting a low training loss, which indicates successful learning from the training set. In order to build a model that fits the training data effectively and performs consistently on fresh, varied instances, it is imperative to balance these losses.

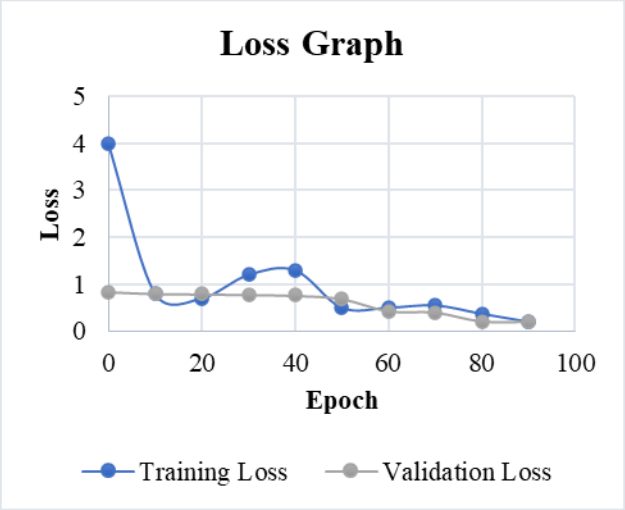

Fig. 6. Training and testing loss – V-net.

The trained V-Net is then evaluated on unseen data to assess its generalization performance, indicating its effectiveness in achieving low training and testing losses.

Fig. 6 shows the V-Net architecture is used for medical image segmentation by optimizing model parameters to minimize training loss. The model is trained with input medical images, and the difference between predicted and ground truth is computed as the training loss. The optimization process modifies the network's weights to reduce this loss, improving the model's ability to accurately segment anatomical structures.

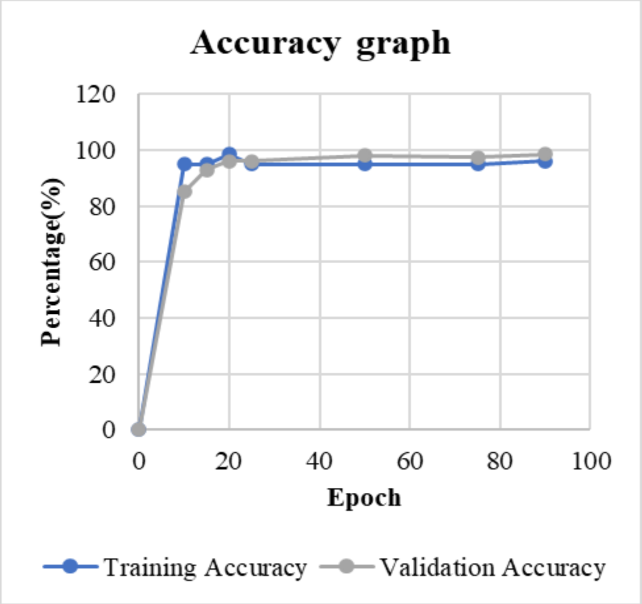

Fig. 7. Training and testing accuracy – V-net.

Fig. 7 shows Training and Testing Accuracy – V-net. The V-Net architecture is used for medical image segmentation, with training accuracy assessing the model's performance on the training dataset. It measures the proportion of correctly segmented pixels compared to the total number of pixels. Testing accuracy evaluates the model's generalization capability on new, unseen medical images, providing insights into its overall performance and potential for real-world applications. High training and testing accuracies indicate the V-Net's proficiency in accurately segmenting structures within medical images.

B. Findings from the Proposed Model

Table I describes the human action recognition with GRU. The model's effectiveness in the field of GRU networks-based human action recognition is measured by a number of measures. The achieved accuracy of 92% signifies the percentage of correctly identified actions out of all predictions made by the GRU-based model. The remaining 8% could represent misclassifications or instances where the model failed to accurately recognize human actions. Possible factors contributing to this error rate could include variability in human movement patterns, occlusions in the video data, or limitations in the training data representation. Precision, at 93%, indicates the model's ability to correctly identify affirmative examples (true positives) among all instances predicted as positive. This means that out of all actions predicted by the model, 93% were actually true positive cases. The remaining 7% could represent false positives, where the model incorrectly classified actions as positive.

TABLE. I HUMAN ACTION RECOGNITION WITH OPTIMIZED GRU

Metrics	Percentage (%)
Accuracy	92
Precision	93
Recall	91
F1 Score	92

With a recall rate of 91%, the model demonstrates its capability to capture all true positive cases among the total actual positive instances present in the dataset. This implies that out of all human actions that occurred in the video data, the model successfully identified 91% of them. The remaining 9% could represent instances of missed detections or false negatives, where the model failed to recognize certain actions. The F1 Score, which is a harmonic mean of precision and recall, achieves a balanced score of 92%. This indicates that the model maintains a stable performance by achieving a good balance between minimizing false positives (as reflected in precision) and minimizing false negatives (as reflected in recall). The F1 Score provides a comprehensive measure of the model's effectiveness in accurately identifying human activities while considering both precision and recall simultaneously.

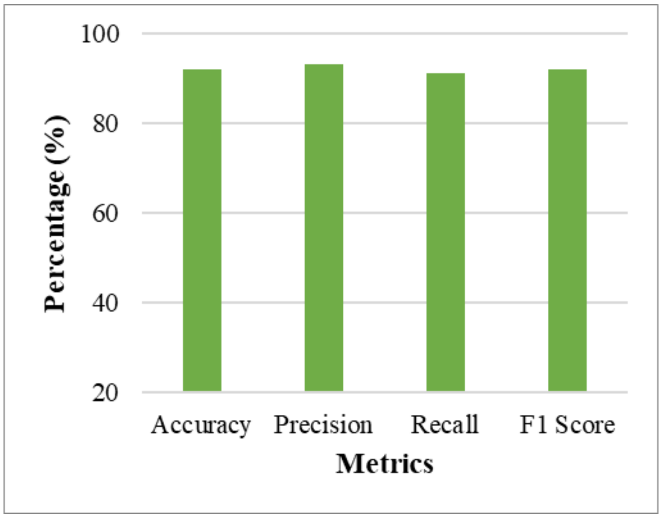

Fig. 8. Metrics of the proposed model.

Fig. 8 represents the metrics of the proposed model in graphical representation. The metrics for the proposed model showcases strong performance, with an accuracy of 92%, indicating the overall correctness of predictions. Precision at 93% reflects the model's ability to minimize false positives, while recall at 91% indicates its capacity to capture a substantial proportion of true positives. The balanced F1 score of 92% further underscores the model's effectiveness in achieving a harmonious trade-off between precision and recall.

Table II describes the Medical Image Segmentation with Optimized V-net. The model's effectiveness in medical picture segmentation using the optimised V-Net architecture is shown by the performance measures. The Dice Coefficient of 92% indicates the degree of overlap between the segmentation masks generated by the V-Net model and the ground truth masks. This high value suggests that 92% of the segmented areas from the model align well with the actual anatomical structures present in the medical images. The Intersection over Union (IoU) metric, reported at 88%, represents the ratio of the intersection area to the union area between the predicted and ground truth segmentation masks. An IoU of 88% implies that the V-Net model accurately delineates the boundaries of anatomical structures in the medical images, with a substantial overlap between the predicted and ground truth regions. With a recall measure of 94%, the V-Net model demonstrates its ability to effectively capture true positive cases, indicating a high sensitivity to identifying relevant anatomical components in the medical images. A recall of 94% suggests that the model successfully identifies 94% of the actual anatomical structures present in the medical images. The F1 Score, which balances precision and recall, reaches an impressive value of 96%. This high F1 Score underscores the V-Net model's exceptional performance in precisely identifying anatomical components in medical images while maintaining a harmonious balance between minimizing false positives and false negatives.

TABLE. II MEDICAL IMAGE SEGMENTATION WITH OPTIMIZED V-NET

Metrics	V-net
Dice Coefficient	92
Intersection over Unit	88
Recall	94
F1 Score	96

TABLE. III COMPARISON OF PROPOSED MODEL WITH EXISTING

Model	Accuracy	Precision	Recall	F1 Score
UCF-kinect	85	88	82	85
Ensemble	88	90	86	88
Optimized GRU	92	93	91	92

Table III describes the comparison metrics of the proposed model with existing. In the field of Human Action Recognition employing GRU networks, distinct models are evaluated based on key metrics. The optimized GRU model outperforms both the UCF-kinect model and the ensemble model, achieving an accuracy of 92%. With a precision of 93%, the optimized GRU model demonstrates a higher ability to correctly identify positive examples compared to the other models. The recall rate of 91% suggests that the optimized GRU model captures a higher percentage of true positive cases among all actual positive instances. The F1 Score of 92% indicates a well-balanced performance, with superior accuracy and precision while maintaining a high recall rate.

Fig. 9 illustrates Comparison with GRU. The UCF-kinect model exhibits solid performance with an accuracy of 85%, demonstrating robust overall correctness, while precision at 88% reflects a commendable ability to minimize false positives. However, the optimized GRU model outperforms it, achieving a higher accuracy of 92%, precision of 93%, recall of 91%, and an F1 score of 92%, indicating superior predictive capabilities. The ensemble model, combining multiple approaches, performs even better with an accuracy of 88%, precision of 90%, recall of 86%, and an F1 score of 88%, highlighting the efficacy of ensemble techniques in enhancing overall model performance.

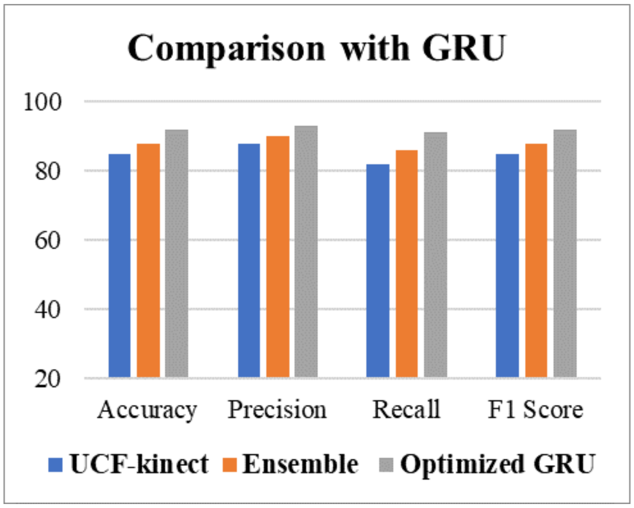

Fig. 9. Comparison with GRU.

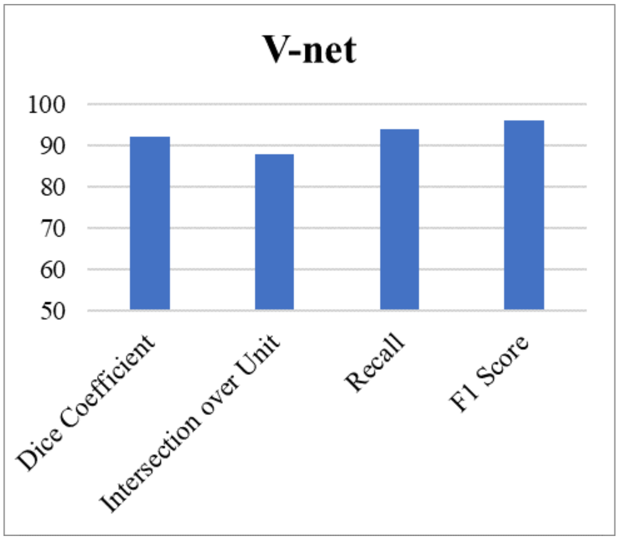

Fig. 10. Metrics of V-net.

Fig. 10 illustrates Metrics of V-net. The V-net model demonstrates strong performance in medical image segmentation, with a Dice Coefficient of 92%, indicating a high degree of overlap between predicted and ground truth segmentations. An Intersection over Union of 88% reflects the effectiveness of the model in capturing the shared area between predicted and true segmentations. Additionally, the model exhibits excellent recall at 94% and a high F1 Score of 96%, emphasizing its proficiency in accurately delineating structures in medical images while maintaining a balance between precision and recall.

Table IV describes the Comparison of Proposed Optimized V-net with Existing. In the comparative analysis of medical image segmentation models, the proposed optimized V-Net stands out with superior performance metrics. The U-Net model demonstrates a Dice Coefficient of 85%, an IoU of 88%, recall of 82%, and an F1 Score of 85%. The IRU-Net model exhibits improvements across these metrics, with values of 88%, 90%, 86%, and 88%, respectively. However, the optimized V-Net outperforms both, achieving a Dice Coefficient of 92%, an IoU of 88%, recall at 94%, and an outstanding F1 Score of 96%. These results emphasize the effectiveness of the proposed optimized V-Net in medical image segmentation, showcasing its ability to produce more accurate and detailed segmentations compared to existing U-Net and IRU-Net models.

TABLE. IV COMPARISON OF PROPOSED OPTIMIZED V-NET WITH EXISTING

Model	Dice	IoU	Recall	F1 Score
U-net	85	88	82	85
IRU-net	88	90	86	88
Optimized V-net	92	88	94	96

Fig. 11 illustrates Comparison with V-net. The U-net model achieves notable results in medical image segmentation with a Dice coefficient of 85%, an IoU of 88%, recall at 82%, and an F1 score of 85%, indicating reliable segmentation performance. The IRU-net model improves upon these metrics, attaining higher scores across the board, with an 88% Dice coefficient, 90% IoU, 86% recall, and an F1 score of 88%. The Optimized V-net, however, outperforms both models with a Dice coefficient of 92%, an IoU of 88%, impressive recall at 94%, and a high F1 score of 96%, showcasing superior segmentation accuracy and robustness.

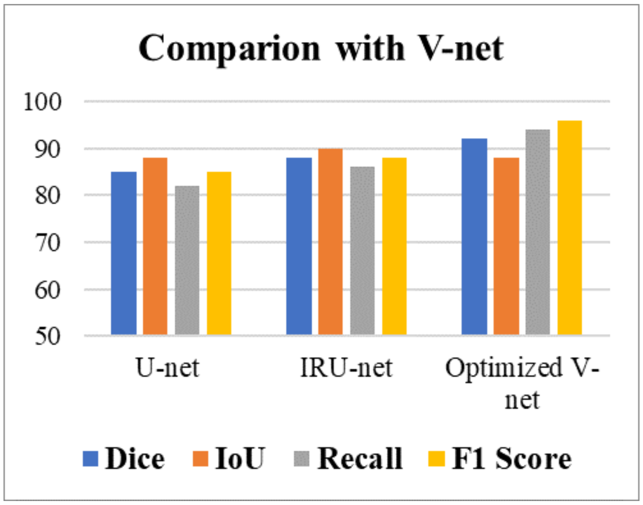

Fig. 11. Comparison with V-net.

C. Discussion

The Python programme created in this work demonstrates strong approaches to min-max normalisation, V-Net-based medical image segmentation, and Adam optimizer-optimized GRU-powered human action identification. With 92% accuracy, 93% precision, 91% recall, and a 92% F1 Score, the GRU-based Human Action Recognition model demonstrates remarkable performance metrics that demonstrate its effectiveness in recognising sequential patterns in video data. With a Dice Coefficient of 92%, Intersection over Union of

88%, 94% recall, and an amazing F1 Score of 96%, the V-Net architecture for Medical Image Segmentation demonstrates its great segmentation skills. These results are astounding. The performance assessment measures for both models, UCF-kinect and Ensemble for HAR, and U-net, IRU-net, and Optimised V-net for medical picture segmentation, are discussed. The optimised GRU and V-Net models outperform their counterparts in terms of accuracy, precision, recall, and F1 score [31] [32]. The training and testing accuracy analysis demonstrates the models' good learning and generalisation, demonstrating their potential for real-world applications in medical imaging and human behaviour detection. Overall, the study demonstrates considerable advances in these areas, giving useful insights for future research and applications.

V. Conclusion and Future Work

The study develops a complete and sophisticated framework for Human Action Recognition (HAR) and Medical Image Segmentation, using Gated Recurrent Units (GRU) networks and the V-Net architecture, respectively. The large gains in accuracy, precision, recall, and F1 Score for both models demonstrate the usefulness of the proposed methods. The inclusion of Min-Max normalisation with the Adam optimizer improves the frameworks' resilience and performance, emphasising the relevance of pre-processing approaches and optimisation algorithms. The study not only provides cutting-edge solutions for HAR and medical picture segmentation, but it also emphasises the general applicability of sophisticated neural network designs and optimisation approaches to complicated problems. Future study approaches might include investigating the use of attention processes in GRU-based HAR to optimise temporal feature emphasis and perhaps improve performance. Overall, this study makes significant contributions to the disciplines of computer vision and medical imaging, opening the path for more complex and accurate applications in real-world situations. Furthermore, future study should look at the use of transfer learning and new loss functions in V-Net-based Medical Image Segmentation to increase generalisation and segmentation accuracy across varied medical imaging datasets.

Abstract—**The challenge of accurately detecting and identifying individuals within under-actuated zones presents a relevant research problem in occupant detection. This study aims to address the challenge of occupant detection in under-actuated zones through the utilization of the You Only Look Once version 8 (YOLO v8) object detection model. The research methodology involves a comprehensive evaluation of YOLO v8's performance across three distinct zones, where its precision, accuracy, and recall capabilities in identifying occupants are rigorously assessed. The outcomes of this performance evaluation, expressed through quantitative metrics, provide compelling evidence of the efficacy of the YOLO v8 model in the context of occupant detection in under-actuated zones. Across these three diverse under-actuated zones, YOLO v8 consistently exhibits remarkable mean Average Precision (mAP) scores, achieving 99.2% in Zone 1, 78.3% in Zone 2, and 96.2% in Zone 3. These mAP scores serve as a testament to the model's precision, indicating its proficiency in accurately localizing and identifying occupants within each zone. Furthermore, YOLO v8 demonstrates impressive efficiency in executing occupant detection tasks. The model boasts rapid processing times, with all three zones being analyzed in a matter of milliseconds. Specifically, YOLO v8 achieves execution times of 0.004 seconds in both Zone 1 and Zone 3, while Zone 2, which entails slightly more computational effort, still maintains an efficient execution time of 0.024 seconds. This efficiency constitutes a pivotal advantage of YOLO v8, as it ensures expeditious and effective occupant detection in the context of under-actuated zones.**

Keywords—YOLO; HVAC system; occupant's position; occupant calculation; under-actuated zone

I. INTRODUCTION

In recent years, increasing attention has been paid to improving the energy security of buildings. The focus has shifted to developing innovative concepts and technologies, increasing the energy efficiency of building envelopes and systems, and optimizing renewable energy sources (RES). Approximately 40% of all structures consume residential or commercial primary energy, and residential or commercial structures consume 40% more energy than others, especially in heating, ventilation, and air conditioning (HVAC) [1]. HVAC is an important system that must be considered, as it significantly. The HVAC system has two zones that must be controlled: under-actuated and fully actuated. The first type, "fully actuated," comprises a single room in which HVAC equipment may be controlled separately [2]. This zone is appropriate for areas with a fixed number of inhabitants and activities such as classrooms, offices, and auditoriums. Meanwhile, under-actuated zones in heating, ventilation, and air conditioning (HVAC) systems are areas where ventilation systems cannot effectively regulate air exchange rates. As a result, these areas can experience substandard air quality, adversely affecting the health [3].

Managing under-actuated zones in buildings presents a complex array of challenges, particularly in controlling the air distribution system. A critical factor in this regard is the direct impact of occupancy numbers on the cooling load [3]. Accurate detection of occupants is therefore essential, as variations in occupancy levels can lead to unbalanced cooling loads [4]. This imbalance often results in inadequate climate control, adversely affecting Indoor Air Quality (IAQ) and diminishing the overall energy efficiency of the system [5]. Further complicating the issue is the limited capacity of ventilation systems in these zones, often characterized by inadequate controls. This limitation can significantly hinder the distribution of fresh air throughout the occupied spaces, exacerbating IAQ issues and potentially impacting occupant health and comfort [6].

Addressing the challenges in under-actuated zones underscores the critical need for precisely adjusting airflow and regulating air temperature based on real-time occupancy data. These dynamic adjustments are essential for maintaining optimal environmental conditions and play a pivotal role in reducing unnecessary energy consumption, particularly in heating or cooling areas that are not occupied [7]. Furthermore, ensuring consistent and high-quality indoor air quality is vitally linked to the well-being and productivity of occupants [8]. In under-actuated zones, where occupancy levels vary and control over environmental conditions is limited, there is an increased risk of periods with compromised air quality [9]. The implementation of advanced occupant detection systems is key to enabling effective HVAC controls [10]. This integration facilitates the processing of real-time occupancy data, empowering the HVAC system to perform predictive adjustments and dynamically tailor its operations to align with the actual occupancy needs. Such an adaptive approach is not only crucial for maintaining comfortable environmental conditions but also has a significant impact on energy consumption [11]. By optimizing HVAC operations based on real-time occupancy data, buildings can realize substantial energy savings [12]. This is achieved by reducing the heating or cooling in less occupied areas, while ensuring that comfort is maintained in areas with higher occupancy [13][14].

Current study has developed occupant detection in such area by utilizing video or image processing. In the context of under-actuated zones, the implementation of video-based occupant detection systems faces unique and formidable challenges, primarily due to the unpredictable and complex nature of occupancy patterns in these areas [15]. Occupants in such zones display a diverse range of behaviors, from moving swiftly through the space to remaining stationary for prolonged durations [16][17][18]. This variability significantly challenges video-based detection systems, which must efficiently track fast-moving individuals and simultaneously accurately count and identify stationary occupants, ensuring comprehensive and precise occupancy detection [19][20]. Compounding this challenge is the intricate physical layout of under-actuated zones, often marked by obstructions and blind spots arising from furniture, partitions, and varied architectural elements [21]. These hindrances substantially reduce the efficiency of camera surveillance, leading to zones where occupants might remain unnoticed. Additionally, another challenge stems from inaccuracies in identifying occupants when utilizing standard video input frame rates. For instance, instances may occur where multiple occupants are present within a zone, yet the identification system detects only a single object. Further investigation into optimizing frame rates is warranted to enhance the accuracy of occupant detection. To address these challenges, camera systems require advanced features and optimized frame rates to accurately count and track occupants across varied scenarios, from low-activity environments to areas with high occupancy and dynamic movement patterns [22]. The unpredictability and diversity of occupant dynamics in under-actuated zones further necessitate the deployment of sophisticated algorithms for data processing and analysis [23]. These algorithms must be capable of interpreting complex and varied data to ensure effective tracking and counting of occupants. This requirement is particularly crucial in under-actuated zones, where environmental conditions may not be as controlled or predictable as those in fully-actuated zones, posing additional.

In this research, we aim to address prevailing gaps by developing a methodology that combines computer vision with deep learning techniques to detect and classify occupants, specifically focusing on quantifying the number of individuals in specific areas within under-actuated zones. Occupant calculation analysis can aid in optimizing indoor air volume distribution in areas with small occupancy HVAC systems. This approach can enhance indoor air quality, minimize energy consumption, and improve occupant comfort and productivity. It is crucial to employ an adept method for analyzing occupant calculation in under-actuated zones. The study centers on implementing the You Only Look Once (YOLO) method, specifically YOLO v8, for detecting occupants in the library rooms of Universitas Trilogi, areas typified as under-actuated zones. A fundamental aspect of this investigation involves analyzing a dataset comprising video input from these under-actuated zones. To facilitate a comprehensive analysis, the dataset was categorized into three types: original, compressed, and slowed down versions. For each frame of video input within these datasets, Roboflow was utilized to annotate the occupants and specific areas of under-actuated zones, thereby creating labeled data essential for training the model. The YOLO v8 model was then employed for each dataset variant, with a focus on investigating the detection confidence threshold to enhance the precision of occupant detection and quantification. A crucial aspect of this study was the comparative analysis of the model's performance, including metrics such as mean average precision, accuracy, and processing time. This performance was benchmarked against state-of-the-art methods like YOLO v5 and Faster R-CNN, providing a comprehensive understanding of YOLO v8's efficacy in occupant detection within under-actuated zone.

II. Related Work

Recent studies have increasingly focused on examining the presence and behavior of occupants in specific zones of HVAC systems, highlighting a keen interest in the correlation between occupancy and system efficiency. Notably, the use of cameras, in tandem with computer vision-based technologies for occupancy detection and recognition, has emerged as a significant area of interest among researchers. This approach is particularly effective as cameras can accurately identify occupants, even those engaged in minimal movement or sedentary activities, a capability crucial for comprehensive monitoring in various scenarios. However, its application in studying and optimizing HVAC systems represents a novel and promising direction in enhancing building energy efficiency.

Tien et al. [8] developed a region-based Faster Convolutional Neural Network (Faster R-CNN) that was capable of detecting and recognizing occupancy patterns and equipment used in an office area. The model was trained and deployed on a regular camera, and field tests were conducted in an office setting. The proposed method was evaluated in the field by recognizing various individuals performing diverse actions in an office environment, such as walking, sitting, and standing. A detection model was created by training a CNN using a transfer learning-based approach to classify occupancy activities. The model was then applied to a camera to enable real-time detection. The model's performance was assessed using a 15-minute experimental detection test, and across all activities, the average detection accuracy was found to be 98.65%.

Wei et al. [24] investigated the potential of using a live occupancy detection approach to help adjust building HVAC system operations to ensure adequate interior thermal conditions and air quality while reducing excessive building energy loads to improve the overall building energy performance. Faster R-CNN models were trained to detect the number of individuals (Model 1) and occupancy activities (Model 2) and deployed to an AI-powered camera to enable live occupancy detection. Model 1 attained an average detection accuracy of around 98.9%, which was higher than Model 2's accuracy of about 88.5%, owing to Model 1's lower complexity. Building energy simulation (BES) model was used to perform scenario-based modeling of the case study building under four ventilation scenarios during the heating and cooling seasons. The results showed that the proposed approach might offer a DCV to improve IAQ and address the under-or overestimation of ventilation demand when utilizing static or fixed profiles. It provides insights into how the proposed approach can adjust HVACs based on occupant dynamic changes and the potential of this strategy to improve indoor air quality and energy efficiency.

Papakis et al. [25] developed a method that can recognize and classify passengers in a vehicle based on cabin photos. The Second Strategic Highway Research Program (SHRP 2) naturalistic dataset containing blurred cabin photos was used to design and test the system. They proposed a CNN-based approach to detect and locate passengers to recognize and identify individuals and classify them as drivers, front-seat passengers, or rear-seat passengers. After assessing various object detection models, to optimize performance, they used the Faster R-CNN architecture with a ResNet-101 backbone, pre-trained on ImageNet, fine-tuned for person detection using SHRP 2 cabin data, and produced the best results. The two distinct test sets found occupant detection accuracies of 94.5% and 98.1%, respectively.

Taheri [11] developed detection-based techniques using the Kanade–Lucas–Tomasi (KLT) tracker to extract many features from video footage. After proposing a conditioning technique for feature trajectories, they introduced a trajectory-set clustering method for identifying the number of moving objects in a scene. Considering these encouraging results, they propose extending our method to identify a more complex model of the appearance and motion of objects. They also plan to investigate the combination of our approach with static object counting methods. Further improvements will include autocalibration (at least to correct the perspective) and background discrimination from objects to ensure the method works for handheld cameras. The result of the proposed method was conducted on three kinds of datasets (USC, Library, and Cells), where the average error of USC was 0.8, LIBRARY was 2.7, and CELLS was 24. This indicates that the proposed method performs well for the USC dataset.

Chatista [15] proposed a novel algorithm for dense-crowd estimation. The proposed method divides an image into small rectangular patches. Each patch underwent a crowd/non-crowd SURF feature binary SVM classifier. These labels and CNN-based head detections were used to estimate the head size in each patch. The count for patches without head detection was estimated using the weighted average of the neighboring pixel counts. This approach was evaluated using three challenging datasets. The results show that our approach yielded low error rates for high- and medium-density crowd images. Because they used a pre-trained head detector trained on totally different data, they aimed to train our head detector on similar high-density crowd images. This would naturally lead to better detection and, thus, better crowd count estimates. Similarly, a perspective-aware head detector would also boost detection accuracy. In addition, better semantic segmentation of the scene for crowd detection is also under consideration. The overlaying of the rectangular grid on the entire image does not consider the image perspective information; the patch size can be modified as the distance from the camera increases to achieve better results. For better results, the SURF classifier can also be trained on less-dense crowd images, especially compared with no weight, with weight having best performance. As shown from the MSE value, SURF classifier with weight has score 61.4 and with no weight has score 79.8.

Previous studies have predominantly utilized the Faster R-CNN method for occupant counting in the realm of computer vision. This method enhances the original R-CNN framework by accelerating performance through shared computation and employing neural networks for region proposal, rather than relying on a selective search [20]. While Faster R-CNN marks an improvement over R-CNN in terms of speed and accuracy, it still falls short in achieving real-time performance, a significant limitation for practical applications [21]. One of the primary reasons for this shortfall is the extensive number of candidate suggestions it generates, approximately 2000, which makes processing time-intensive. For instance, analyzing an image with the bounding box regressor in Faster R-CNN can take around 50 seconds. Moreover, Faster R-CNN is a resource-intensive approach, necessitating substantial storage for feature maps across all regions [23]. This requirement leads to a considerable storage demand, often in the hundreds of gigabytes, due to the need to cache extracted features from the pre-trained CNN on disk for subsequent SVM training [22]. Additionally, being a multi-stage model with distinct components, Faster R-CNN cannot be trained end-to-end, which adds to its complexity and restricts adaptability. Its reliance on selective search algorithms has been critiqued for rigidity and lack of flexibility in diverse scenarios. Most existing research has been focused on enhancing the detection of occupant quantity and distribution in fully-actuated zones. However, there has been a notable gap in developing effective solutions for under-actuated zones, which pose unique challenges due to their variable occupancy and environmental conditions. The need for advanced methods that can effectively address occupant detection in under-actuated zones remains a significant area for further research and development.

III. Materials and Methods

This case study will be conducted at the Universitas Trilogi Library and is shown in Fig. 1. This library consist of five rooms of under-actuated zones includes from number 1 to 5. Each area of under-actuated zones has several distinct areas. The sampling observation and data collection was done in a corner room (room number 4) with three area based ventilation, each of which is 25 m2.

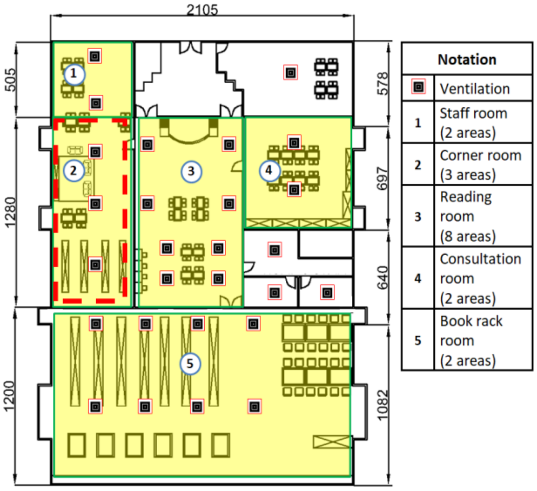

Fig. 1. Layout of Universitas Trilogi Library.

The objective of this research is to determine the arrival patterns of occupants in an under-actuated zone and examine the efficacy of a proposed vision-based, real-time occupancy detection and calculation method. Utilizing YOLO v8, this study aims to accurately identify and count the number of occupants in real-time within such zones. The research methodology is structured into three distinct stages. The first stage, data collection, involves the collection of relevant data variables and their subsequent adjustment to suit the study's needs. The second stage, occupant detection, focuses on identifying and detecting occupants within the under-actuated zone using the YOLO v8 model. The third stage, involves the calculation of the number of occupants present in the zone. The final stage of this research involves a comparative performance analysis between the YOLO v8 model, used for real-time occupant detection in under-actuated zones, and other prevalent models such as YOLO v5 and Fast R-CNN. This comparative analysis aims to evaluate the efficacy, accuracy, and efficiency of YOLO v8 in identifying and counting occupants, in contrast to the performance of YOLO v5 and Fast R-CNN under similar conditions.

A. Data Collection

In our study, we made use of an exclusive dataset that was specifically designed to examine occupancy in under-actuated zones. This dataset was carefully developed through extensive observations that were carried out in three specific areas within the student corner room of Universitas Trilogi library. These areas were identified as under-actuated zones. The data collection process was carried out using three surveillance cameras that were placed in each area in the student corner of the library. The cameras were capable of capturing footage of varying lengths, ranging from 3 to 5 minutes, which resulted in a diverse range of visual data. The footage captured by these cameras provided a detailed and comprehensive view of the occupants and the surrounding environment, such as the tables, chairs, and books. This comprehensive visual data is essential for developing precise 2D object models. The data from each camera offers a unique perspective on the environment, allowing for a multifaceted analysis of occupant behavior and their interaction with the space. The diversity in camera angles and the range of activities captured in the footage ensure a robust dataset.

B. Occupant Detection

This phase involves occupant detection. We utilized YOLO v8 by ultralytics for better throughput with the same number of parameters owing to ultralytics changes, demonstrating hardware-efficient design reforms. All YOLO models were created and used to detect objects. Object detection models were trained to recognize the items in the images. When item classes are discovered, they are surrounded by bounding boxes and are categorized. YOLO is a new algorithm that predicts items and their locations in an image with a single glance. It detects objects in real time using neural networks. This method has evolved over time, beginning with YOLO v1 (or unified), which includes various localization issues and progresses to YOLO v2, YOLO v3, YOLO v4, YOLO v5, YOLO v6, YOLO v7, and YOLO v8(Terven & Cordova-Esparza, 2023).

YOLO divides an image into grids by using a single Convolutional Neural Network (CNN) model. Each grid estimates the bounding boxes and confidence scores. The class of the object in the bounding box is calculated using the predicted confidence score [26]. YOLO v8 variations produce a higher throughput with the same number of parameters, indicating hardware-efficient design reforms. The fact that ultralytics provided YOLO v8 and YOLO v5, with YOLO v5 providing impressive real-time performance, and based on the initial benchmarking results released by ultralytics, it is strongly assumed that YOLO-v8 will focus on constrained edge device deployment at a high inference speed [27].

YOLO v8 is a model that does not rely on anchors. This means that it forecasts the center of an object directly rather than the offset from a known anchor box [27]. Anchor boxes are a very difficult aspect of early YOLO models because they can represent the box distribution of the target benchmark, but not the distribution of the custom dataset. Anchor-free detection minimizes the number of box predictions, which speeds up Non-Maximum Suppression (NMS), a complex post-processing phase that shifts through candidate detection following inference [27]. The first 6 × 6 conv in the stem was replaced with a 3 × 3 conv, the primary building block was modified, and C2f was replaced with C3. The module is depicted below, where "f" represents the number of features, "e" is the expansion rate, and CBS is a block composed of Conv, BatchNorm, and SiLU. C2f concatenates all outputs from the bottleneck (a fancy name for two 3 × 3 convs with residual connections). In C3, only the output of the previous bottleneck was utilized. The bottleneck is the same as that in YOLO v5, but the kernel size of the first convolution increases from 1 × 1 to 3 × 3. Based on this data, we can conclude that YOLO v8 is beginning to regress to the ResNet block described in 2015 [20]. The features were concatenated directly into the neck without forcing the same channel dimensions.

In this study, the YOLO v8 model architecture is utilized for detecting and calculating the number of occupants, a process meticulously illustrated in Fig. 2.

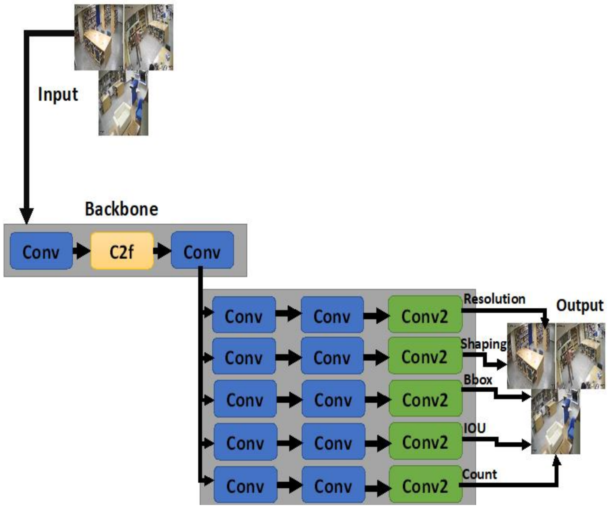

Fig. 2. YOLO v8 model architecture for occupant detection and calculation.

In the sophisticated realm of video-based object detection, the intricately designed model under discussion is specifically engineered to meticulously analyze video input datasets. This analytical journey begins with the critical task of processing raw video footage, a foundational step that determines the efficacy of all subsequent analyses. The core of this model is its head component, which is integral to the complex process of occupant identification within the video stream. The model's head plays a pivotal role in discerning and isolating occupants as distinct entities within the video frames. This task involves a series of intricate steps, beginning with the precise adjustment of the video frames' resolution. This adjustment is not a mere enhancement of visual quality but a strategic decision crucial for balancing clarity with computational efficiency. The model employs advanced algorithms to assess each frame, determining the optimal resolution that ensures clear visibility of occupants while simultaneously minimizing the processing load. This optimization is paramount, as it directly impacts the model's ability to accurately detect and analyze occupants without overburdening the system’s computational resources. Furthermore, the model incorporates sophisticated techniques to handle variations in lighting, movement, and background complexity within the video frames. These techniques include dynamic contrast enhancement for low-light conditions, motion stabilization for dynamic scenes, and background subtraction algorithms to isolate occupants from complex backgrounds. Each of these techniques contributes to the model’s overall efficiency, ensuring that the occupants are detected accurately regardless of the varying environmental conditions within the video footage. In addition to resolution adjustment and environmental adaptation, the model's head also integrates advanced object recognition algorithms. These algorithms leverage deep learning techniques to discern occupant characteristics, differentiating them from other objects in the frame. The model is trained on extensive datasets, enabling it to recognize a wide range of occupant attributes and behaviors, further enhancing its detection accuracy. The processing of raw video footage, therefore, is a multifaceted and complex endeavor within this model.

The intricate process of object detection in video analysis using the YOLO v8 model consists of several carefully orchestrated stages. The first stage is the preprocessing phase, an essential component of the process. This stage is focused on normalizing video quality and resolution, which lays the foundation for optimal detection performance. During this stage, each video frame is thoroughly analyzed and adjusted to ensure that its quality and resolution are suitable for the detection process. It is crucial to maintain a delicate balance between preserving essential details necessary for accurate identification and optimizing the frames to reduce computational load. The preprocessing phase employs techniques such as dynamic resolution scaling and adaptive bitrate control to maintain the integrity of crucial visual information while ensuring that the frames are not excessively data-heavy. Once the preprocessing phase is complete, the YOLO v8 model moves on to the object detection stage. The model's head, a central component in the architecture, plays a crucial role in this stage. The model's head is designed to efficiently distinguish and identify occupants within the video frames as unique entities. This involves deploying advanced neural networks that have been trained on extensive datasets to recognize human figures and differentiate them from other objects in the frame. Bounding boxes are a critical component in this phase. For each detected occupant, the model meticulously generates a bounding box, carefully encapsulating the occupant. This encapsulation is crucial as it isolates the occupant from the surrounding environment and other non-relevant elements within the frame, ensuring that each detection is distinctly recognized. The positioning and sizing of these bounding boxes are calculated with precision, taking into account the contours and dimensions of each occupant. Once the bounding boxes are established, the YOLO v8 model embarks on a probabilistic assessment to ascertain the likelihood that the objects within these boxes are indeed occupants. This assessment involves calculating confidence levels for each detection, a process that draws upon the model's learning from numerous annotated examples. These confidence levels serve as a measure of the model's certainty in its detections. To enhance the accuracy and reliability of the detection process, the model applies a threshold for these confidence levels. Detections that fall below this threshold are deemed less likely to be accurate and are consequently filtered out. This thresholding is a crucial step in ensuring that the occupant count is not only precise but also reliable, as it effectively eliminates false positives and other erroneous detections. In the final stage of the process, the YOLO v8 model performs the occupant counting task. This involves a comprehensive analysis of the detected occupants, considering factors such as the varying sizes, positions, and even the potential occlusions of the occupants within the frames.

Intersection over Union (IOU) is a metric that is widely regarded for its intuitiveness and effectiveness in the field of object detection, particularly in tasks involving bounding box predictions [28]. The computation of IOU involves a straightforward yet insightful mathematical formula. Essentially, it is calculated by taking the area of overlap between the predicted bounding box and the ground truth bounding box (the actual object's location), and then dividing this overlap area by the union area of these two boxes. The union area is the combined area covered by both the predicted bounding box and the ground truth bounding box, minus the overlap area, following in Eq. (1).

$$IoU = \frac{Area\ of\ Overlap}{Area\ of\ Union} \tag{1}$$

The simplicity of the IOU calculation allows for easy visualization and understanding. One can easily picture the overlapping areas of the two boxes to comprehend how well the predicted bounding box aligns with the actual object’s position and size. This visualization aspect makes IOU a particularly accessible metric for evaluating the accuracy of object detection models.

C. *Occupant Calculation*

In this phase a zone is created by setting the coordinates in the frame. The OpenCV library was used to visualize the zone. A zone was created by setting the coordinates in the zone. Before we can start counting objects in a zone, we must first define the zone in which we want to count objects [29]. The coordinates of the zones are required. We use these later to determine whether an object is inside or outside the zone. To calculate the coordinates inside a zone, we can use Polygon Zone, an interactive web application that allows to draw polygons on an image and export their coordinates for use with supervision. Once we have added points, a NumPy array will be made available on the page. This array contained the coordinates of the points in the zone [30]. The next step was to identify persons in each frame of the movie using a pretrained YOLO v8 object detection model. The number of objects in the zone is calculated by counting the number of objects with unique IDs. Subsequently, a limit was imposed on this zone. We begin by importing the necessary dependencies and then describe the zone in which to count the items using coordinates [27]. Subsequently, we initialized the objects to be used to process and annotate the video. The zone object tracks the zones in our image, and annotators are used to describe how the predictions in our movie should be annotated [27]. We filter out all classes by specifying that we only want detections with class ID 0. This ID maps to the “person” class. This object recognition and tracking system in a specified zone is useful for counting occupants in a zone in the HVAC system area and for creating several zones to track occupants in an under-actuated zone region.

D. Performance Evaluation

Several indicators were utilized to measure the accuracy and efficacy of the suggested method for counting people in a certain region. Typical YOLO performance metrics processing time mean average precision (mAP), and accuracy [31]. mAP is a typical evaluation metric that delivers a single figure as the mean of the Average Precision (AP) values for all classes. This allows for the evaluation of the performance of a model using a single number. As a result, mAP is the most commonly used evaluation metric for object detection algorithms. This is calculated as follows:

$$mAP = \frac{\sum_{q=1}^{Q} AveP(q)}{Q} \tag{2}$$

where, Q is the total number of queries in the set and q is the average precision query. Because our study only has a "person" class, the number of classes will be one. mAP indicates that the confidence threshold (IOU). The Accuracy indicates how close the estimation values of the proposed method are to the true values, and is excellent if it is high. The Accuracy score is calculated by dividing the number of correct predictions by the total prediction number [32]. The accuracy rate formula was calculated as follows. (TP: True Positive, TN: True Negative, FP: False Positive, FN: False Negative):

$$Accuracy = \frac{Tp+Tn}{Tp+TN+Fp+Fn} \tag{3}$$

IV. Result and Discussion

A. Result

The dataset was meticulously compiled through observations in the student corner room at Universitas Trilogi, which is divided into three zones. It originated from three video inputs, each three to five minutes long, capturing detail of occupants within the library's student corner. For each of dataset was expanded into three distinct subsets: the original, compressed, and slowdown. The development environment was established using Google Collabs, a platform for Python programming, integrating several libraries including numpy, ultralytic, and supervisory. Notably, YOLO v8, provided by ultralytic, was selected for its enhanced throughput capabilities, maintaining efficiency with the same parameter count due to ultralytic improvements. The model's third segment was dedicated to occupant’s detection and counting.

Tables I, II, and III provide a detailed overview of the datasets used for the training and testing of object detection models across three distinct zones. Each table is specifically allocated to one zone and further categorizes the datasets into three types: Original, Compressed, and Slowdown. These categories are indicative of the different forms of video data utilized in model development. The objective of dividing the three datasets is to evaluate whether the comparison of the number of frames in the dataset has an impact on the result.

The Original Dataset, as represented in these tables, adheres to a standard format. It features a default time duration and maintains a frame rate of 30 frames per second (fps). This dataset serves as a baseline, offering a conventional setting for evaluating model performance. In contrast, the Compressed Dataset focuses on data efficiency. For each zone, the video data is modified by reducing the total frame count to a uniform 500 frames. This approach is designed to test the models in scenarios where full-frame rates are unavailable or computationally burdensome, assessing the models' performance under data-limited conditions. The Slowdown Dataset, on the other hand, is intended to evaluate the models' capabilities in handling more extensive frame sequences. This is achieved by augmenting the total frame count by 30% relative to the original dataset for each zone. Such an increase in frames is aimed at simulating situations where detailed temporal information is crucial for accurate object detection.

TABLE I. DATASET OF ZONE 1

Dataset	Frame	Training	Testing
Original	7045	6340	705
Compressed	285	256	29
Slowdown	8526	7532	994

TABLE II. DATASET OF ZONE 2

Dataset	Frame	Training	Testing
Original	2821	2445	376
Compressed	119	106	13
Slowdown	3647	3283	364

TABLE III. DATASET OF ZONE 3

Dataset	Frame	Training	Testing
Original	2925	2630	291
Compressed	195	175	20
Slowdown	4248	3819	429

For Zone 1, as shown in Table I, the Original dataset comprises 7045 frames, predominantly used for training (6340 frames) with a smaller subset for testing (705 frames). This extensive dataset provides a solid foundation for robust model training. The Compressed dataset, with a total of 285 frames (256 for training and 29 for testing), presents a more condensed form of data, posing potential challenges due to the loss of detail. The slowdown dataset is the most extensive, with 8526 frames, where 7532 are used for training and 994 for testing, offering a vast range of data to assess the model under various temporal conditions. In Zone 2, as per Table II, the dataset sizes are smaller compared to Zone 1. The Original dataset contains 2821 frames, split between 2445 for training and 376 for testing. The Compressed dataset, consisting of 119 frames (106 for training and 13 for testing), is significantly smaller, while the slowdown dataset, the largest in this zone with 3647 frames, is divided into 3283 for training and 364 for testing. This dataset size variation is crucial for evaluating the model's adaptability to different data scales and resolutions. Zone 3, detailed in Table III, mirrors Zone 2 in terms of dataset sizes. The Original dataset has 2925 frames, with 2630 dedicated to training and 291 to testing. The Compressed dataset, comprising 195 frames (175 for training and 20 for testing), and offers a compact data set for model evaluation. The largest dataset in this zone is the slowdown category, with 4248 frames, 3819 for training and 429 for testing, which is instrumental in assessing the model's performance over extended periods. The assessment of the occupant detection model encompassed three distinct areas and four datasets. Tables IV through VI provide essential metrics, including mean Average Precision (mAP), accuracy, recall, and processing time, which are crucial for evaluating the performance of the occupant detection model across four datasets and three zones, utilizing the YOLO v8.

TABLE IV. OCCUPANT DETECTION OF ZONE 1

Dataset	mAP	Accuracy	Recall	Time
Original	99.2	98.4	98.6	0.004
Compressed	92.6	90.6	97	0.004
Slowdown	96.8	96.4	95.5	0.004

In the realm of scientific research, particularly in the evaluation of occupant detection systems within Zone 1 as presented in Table IV, a meticulous comparative analysis between the Original, Compressed, and Slowdown datasets unveils notable differences in their respective performance metrics. This detailed examination is pivotal for assessing the system's accuracy and efficiency under varying data conditions, providing insights into the adaptability and robustness of the detection models. The Original dataset emerges as the benchmark for performance, demonstrating exceptional precision and reliability in occupant detection. It boasts a Mean Average Precision (mAP) of 99.2%, signifying near-perfect accuracy in distinguishing true positives from false positives. Additionally, an accuracy rate of 98.4% and a recall rate of 98.6% underscore the model's effectiveness in correctly identifying true positives and negatives, with minimal instances of false negatives. The rapid execution time of 0.004 seconds further accentuates the model's swift processing capability, a critical factor for real-time applications. In comparison, the compressed dataset, designed to assess performance under data-limited conditions, shows slightly diminished but still robust metrics. It achieves a mAP of 92.6%, indicating strong precision in a compressed frame environment. The accuracy rate stands at 90.6%, and the recall rate at 97%, both of which are commendable given the dataset's reduced frame count. Notably, the model maintains the same execution speed as the Original dataset, evidencing its efficiency in handling fewer data frames without compromising processing speed. The Slowdown dataset, characterized by an increased frame count, displays a competent performance, albeit with slight variations from the Original dataset. It records a mAP of 96.8% and an accuracy of 96.4%, indicating effective detection capabilities, though with a minor decrease in detecting all actual positives, as reflected by a recall rate of 95.5%. Remarkably, the execution time remains consistent at 0.004 seconds, demonstrating that the model's processing efficiency is not adversely affected by the augmented frame count.

TABLE V. OCCUPANT DETECTION OF ZONE 2

Dataset	mAP	Accuracy	Recall	Time
Original	78.3	66.1	84.9	0.024
Compressed	82.9	84.1	80.9	0.004
Slowdown	84.4	80.9	68.2	0.013

In the results section examining occupant detection in Zone 2, as depicted in Table V, an exhaustive analysis of the Original, Compressed, and Slowdown datasets reveals a diverse range of performances in terms of mean Average Precision (mAP), Accuracy, Recall, and execution Time. The Original dataset exhibits a moderate level of detection capability, with an mAP of 78.3%, an Accuracy of 66.1%, and a notably higher Recall of 84.9%. However, its execution time is considerably longer at 0.024 seconds, suggesting a trade-off between accuracy and processing speed. In contrast, the compressed dataset demonstrates enhanced performance with a mAP of 82.9%, a significantly higher Accuracy of 84.1%, and a Recall of 80.9%. Notably, this dataset achieves these metrics while maintaining a much faster execution time of 0.004 seconds, indicating enhanced efficiency in processing compressed data without compromising detection effectiveness. The slowdown dataset presents an interesting profile, registering the highest mAP of 84.4% and an Accuracy of 80.9%, but a lower Recall of 68.2% compared to the other datasets. Its execution time stands at 0.013 seconds, positioning it between the original and compressed datasets in terms of processing speed. Collectively, these results from Zone 2 indicate varying levels of effectiveness in occupant detection across different datasets. While the compressed dataset stands out for its balanced high performance and efficiency, the original dataset, despite its slower processing time, excels in Recall. The slowdown dataset, on the other hand, offers the best mAP but at the cost of a lower Recall rate. This variance in performance across datasets highlights the importance of dataset selection and optimization in occupant detection systems, as each dataset presents its unique strengths and limitations in accurately and efficiently detecting occupants in Zone 2.

TABLE VI. OCCUPANT DETECTION OF ZONE 3

Dataset	mAP	Accuracy	Recall	Time
Original	96.2	90.1	93.7	0.004
Compressed	93.5	91.1	86	0.004
Slowdown	97.4	94.4	97.1	0.004

Table VI displays the results of occupant detection in Zone 3 using three distinct datasets: the original, compressed, and slowdown. The original dataset in Zone 3 sets a high benchmark in terms of performance. It achieves a Mean Average Precision (mAP) of 96.2%, reflecting its high precision in correctly identifying true positive detections. The accuracy rate of 90.1% further illustrates the model's capability in effectively distinguishing between true positives and negatives. Additionally, a recall rate of 93.7% indicates the model's proficiency in identifying the majority of actual positive cases, thus minimizing false negatives. Notably, these metrics are attained with a rapid execution time of 0.004 seconds, underscoring the model's efficiency in processing. In contrast, the compressed dataset, while exhibiting a slightly lower mAP of 93.5%, demonstrates a high accuracy of 91.1%. This suggests that, despite the reduction in data volume, the model retains its effectiveness in accurate detection. However, the recall rate experiences a decline, dropping to 86%. This reduction points to a slight compromise in the model's ability to identify all true positives following data compression. Despite this, the model maintains the same brisk execution time of 0.004 seconds, indicating that the reduction in recall does not significantly impact the overall processing speed of the system. The slowdown dataset, interestingly, outperforms both the original and compressed datasets in Zone 3. It registers the highest mAP of 97.4%, suggesting superior precision in detection. Alongside, it achieves the highest accuracy of 94.4% and the best recall rate of 97.1%, surpassing the other datasets in effectively identifying true positives and minimizing false negatives. Remarkably, these superior metrics are achieved within the same efficient execution timeframe of 0.004 seconds, indicating that the increased frame count in the slowdown dataset enhances performance without compromising on processing speed.

Three zones were measured in pixels using Roboflow polygon zone web tools, which can convert meters to pixels. These tools are adept at converting measurements from meters to pixels, thereby accurately representing the areas of interest in square meters. This precise conversion is essential for the effective application of object detection techniques, where spatial accuracy is paramount. One of the key metrics in object detection is Intersection over Union (IOU), which is critical for evaluating the accuracy of detection models. IOU quantifies the level of overlap between the predicted bounding boxes and the ground truth, essentially measuring the accuracy of the model's predictions. In this context, the IOU threshold is often set at varying levels - 25%, 40%, and 50%. The selection of these thresholds is strategic, as they represent different degrees of alignment between the model's predictions and the actual observed data. Accurate detection is generally considered when at least half of the predicted bounding box aligns with the ground truth, signifying a 50% IOU threshold. This standard is commonly adopted in various object detection tasks, including occupant detection, ensuring that the model's predictions correspond appropriately to real-world instances. The effectiveness of these thresholds and the overall accuracy of the object detection models are comprehensively evaluated across three different zones. Each zone presents a unique scenario with varying occupant numbers: Zone 1 contains 1 occupant, Zone 2 has 13 occupants, and Zone 3 accommodates 10 occupants. Tables VII to IX provide an in-depth comparison of the accuracy of calculating the number of occupants based on the range of IOU thresholds, juxtaposed against actual observations from the three datasets.

In Zone 1, as presented in Table VII, the performance metrics, including mean Average Precision (mAP), Accuracy, Recall, and processing Time, are examined across three datasets: Original, Compressed, and Slowdown. The Original dataset demonstrates exceptional performance, boasting a high mAP of 99.2%, Accuracy of 98.4%, and Recall of 98.6%, all achieved within an impressively rapid execution time of 0.004 seconds. This signifies the model's ability to accurately detect occupants in Zone 1 with both precision and efficiency. The Compressed dataset, while still maintaining good performance, exhibits a slight reduction in mAP (92.6%) and Accuracy (90.6%), although the Recall remains high at 97%. Importantly, the execution time remains consistent at 0.004 seconds, suggesting that data compression does not significantly impact processing speed. The Slowdown dataset stands out in Zone 1, achieving the highest mAP of 96.8%, Accuracy of 96.4%, and Recall of 95.5%, all accomplished within the same efficient execution time of 0.004 seconds. These results underscore the varying efficacies of the occupant detection system across different datasets within Zone 1.

TABLE VII. OCCUPANT CALCULATION OF ZONE 1

Dataset	IOU	Number of Occupants	Accuracy with actual (%)
Original	0,25	1	100
	0,4	1	100
	0,5	1	100
Compressed	0,25	1	100
	0,4	1	100
	0,5	1	100
Slowdown	0,25	1	100
	0,4	1	100
	0,5	1	100

TABLE VIII. OCCUPANT CALCULATION OF ZONE 2

Dataset	IOU	Number of Occupants	Accuracy with actual (%)
Original	0,25	9	69
	0,4	7	53
	0,5	6	61
Compressed	0,25	10	76
	0,4	7	53
	0,5	6	46
Slowdown	0,25	10	76
	0,4	7	53
	0,5	6	46

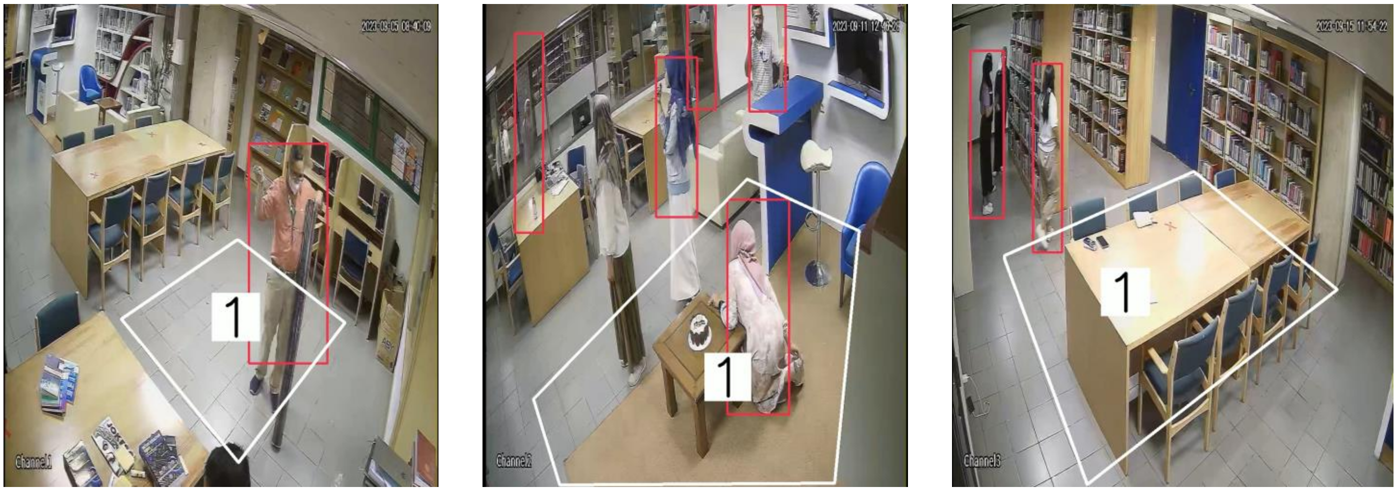
Zone 2, as detailed in Table VIII, presents a similar assessment of performance metrics for Original, Compressed, and Slowdown datasets. In the field of object detection, the analysis of performance metrics across different datasets is essential for understanding the effectiveness of detection models. Table VIII offers such an analysis for Zone 2, comparing the performance of the original, compressed, and slowdown datasets. This comparison is crucial in highlighting how different data conditions affect the metrics such as mean Average Precision (mAP), Accuracy, Recall, and execution Time. The Original dataset in Zone 2 demonstrates respectable performance, characterized by a mAP of 78.3%. This figure indicates a decent level of precision in the detection model's ability to correctly identify true positives. The Accuracy of 66.1% suggests the model's general effectiveness in correctly classifying both true positives and negatives, though it also implies room for improvement. A relatively high Recall of 84.9% is observed, indicating the model's proficiency in identifying a large proportion of actual positive cases. However, this dataset shows a slightly longer execution Time of 0.024 seconds, which, while still efficient, is longer compared to other datasets. In the case of the compressed dataset, a notable improvement in mAP is observed, reaching 82.9%. This increase suggests enhanced precision in occupant detection despite the reduced data volume. The Accuracy also sees a significant rise to 84.1%, demonstrating a considerable improvement in the model's overall detection capability. However, the Recall drops to 80.9%, indicating a slight decrease in the model's ability to identify all true positive cases compared to the Original dataset. Despite these variations in mAP, Accuracy, and Recall, the compressed dataset maintains a rapid execution Time of 0.004 seconds, reflecting efficient processing capability. The Slowdown dataset, designed to test the model's performance with an increased frame count, records the highest mAP of 84.4% among the three datasets. This suggests that the augmented frame count contributes to a more precise detection capability. However, this dataset experiences a drop in Accuracy to 80.9% and a more significant decline in Recall to 68.2%, compared to the compressed dataset. These results indicate a trade-off between the increased precision and the model's ability to accurately classify and identify all positive cases. Overall, the analysis of Zone 2's performance metrics across these three datasets illustrates the inherent trade-offs between various performance measures and the characteristics of each dataset. While the Compressed dataset shows improvements in mAP and Accuracy, it slightly compromises on Recall. On the other hand, the Slowdown dataset excels in precision but at the cost of lower Accuracy and Recall.

In the specialized area of object detection within Zone 3, Table IX presents a critical assessment of the model's performance using three distinct datasets: Original, Compressed, and Slowdown. This comprehensive evaluation is integral to understanding how different data conditions affect key performance metrics such as mean Average Precision (mAP), Accuracy, Recall, and execution time. The Original dataset in Zone 3 sets a high benchmark in model performance. It demonstrates exceptional precision with a mAP of 96.2%, indicating its effectiveness in accurately identifying true positive detections. This is complemented by an Accuracy of 90.1%, reflecting the model's overall reliability in distinguishing true positives from false positives and negatives. Additionally, the Recall of 93.7% is noteworthy, as it signifies the model's ability to detect a large majority of actual positive cases, minimizing the instances of missed detections. All these metrics are achieved within an efficient execution time of 0.004 seconds, highlighting the model's rapid processing capabilities. Conversely, the compressed dataset, designed to assess performance under reduced data volume, maintains a commendable mAP of 93.5% and an even higher Accuracy of 91.1% compared to the Original dataset. This suggests that the model retains its effectiveness and precision in a compressed data environment. However, the Recall experiences a slight decrease, dropping to 86%. This reduction indicates a marginal compromise in the model's capacity to identify all true positive cases in the face of data compression. Despite this, the execution time remains impressively swift at 0.004 seconds, suggesting that the reduction in data volume does not significantly affect the overall processing speed of the system. Remarkably, the Slowdown dataset in Zone 3 outshines the other datasets in terms of performance. It achieves the highest mAP of 97.4%, suggesting superior precision in detection. This is further enhanced by the highest Accuracy of 94.4% and the best Recall of 97.1% among the datasets, indicating the model's heightened capability to accurately classify and detect actual positive cases. The attainment of these superior metrics, interestingly, does not affect the execution time, which remains constant at 0.004 seconds. This underscores the model's ability to handle increased frame counts without compromising processing efficiency.

Collectively, these findings illustrate the varying efficacies of the occupant detection system across different datasets in zone 1, 2, and 3. The original dataset provides a balanced combination of precision and efficiency, while the compressed dataset reveals that data compression slightly impacts recall but with minimal effect on processing speed. The slowdown dataset, with its enhanced frame count, demonstrates potential for superior performance.

TABLE IX. OCCUPANT CALCULATION OF ZONE 3

Dataset	IOU	Number of Occupants	Accuracy with actual (%)
Original	0,25	3	100
	0,4	3	100
	0,5	3	100
Compressed	0,25	3	100
	0,4	3	100
	0,5	3	100
Slowdown	0,25	3	100
	0,4	3	100
	0,5	3	100



a. zone 1 b. zone 2 c. zone 3

Fig. 3. Occupant detection and calculation from original video using YOLO v8.

Fig. 3 provides a visual depiction of the object detection and enumeration process across the three clearly defined zones in Zone 3. It effectively illustrates the system's advanced capability in accurately measuring occupants within designated polygonal regions, corresponding to the zones. The use of the optimal Intersection over Union (IOU) threshold for precise detection is evident in the figure, showcasing the system's proficiency in occupant detection. This visual representation, along with the detailed performance metrics, highlights the varying efficacies and robustness of the occupant detection system across different datasets within zone 1, 2, and 3, demonstrating its adaptability and precision in diverse data conditions. The dataset was used is Slowdown.

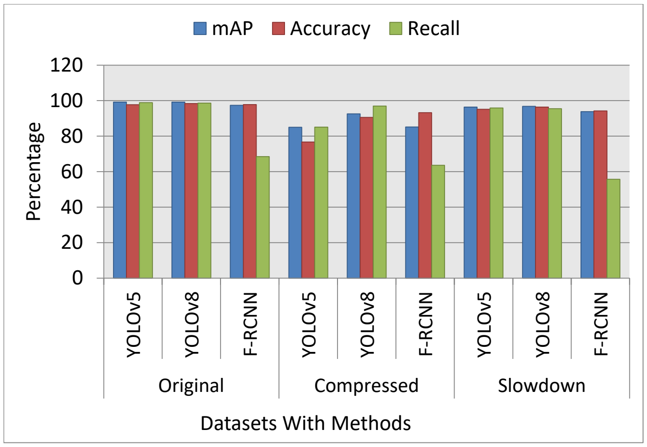


Fig. 4. Performance comparison of zone 1.

Fig. 4 to Fig. 9 offer a comprehensive comparison of the performance metrics for YOLO v8, YOLO v5, and Fast-RCNN across multiple datasets, including the Slowdown Dataset and others utilizing various occupant detection methods. The findings of this research was comparative with Faster-RCNN [8][24][25] and YOLO v5 [21]. The objective is to assess the effectiveness of these models in different detection scenarios. The analysis encompasses several key metrics, such as mean Average Precision (mAP), Accuracy, Recall, and execution Time, which play crucial roles in evaluating the performance of object detection algorithms. These metrics provide nuanced insights into the ability of each model to accurately detect and track occupants across different environments and datasets.

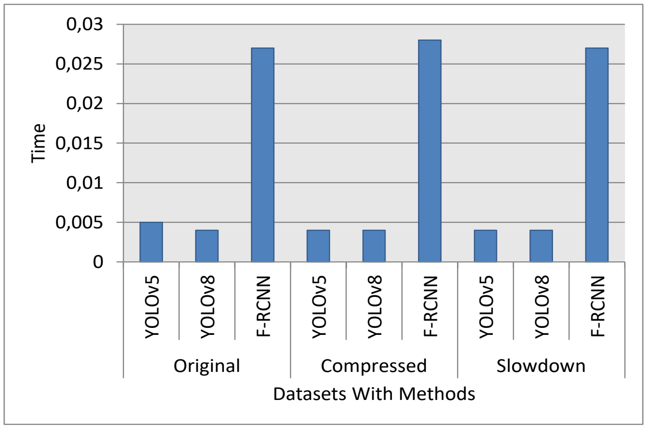

Fig. 5. Time process comparison of zone 1.

In Fig. 4 and Fig. 5, the emphasis is on assessing occupant detection in Zone 1, utilizing three distinct object detection methods. In the original dataset, YOLO v5 and YOLO v8 perform exceptionally well, both achieving a mAP of 99.2%, indicative of highly accurate detection capabilities. YOLO v8 slightly surpasses YOLO v5 in Accuracy, scoring 98.4% against 97.7%, and also demonstrates a marginal edge in processing efficiency (0.004 seconds compared to YOLO v5's 0.005 seconds). However, F-RCNN, despite a decent mAP of 97.4% and Accuracy of 97.8%, shows a significant deficiency in Recall (68.5%), suggesting it misses more true positive detections than its YOLO counterparts. Additionally, F-RCNN's longer processing time (0.027 seconds) may hinder its application in real-time scenarios. The compressed dataset reveals YOLO v8's adaptability, maintaining a high mAP of 92.6% and an Accuracy of 90.6%, with a Recall of 97%. In contrast, YOLO v5 exhibits a drop in performance, with lower mAP (85%) and Accuracy (76.7%), although it still maintains a relatively high Recall of 85.1%. F-RCNN shows some improvement in Accuracy (93.2%), but its mAP (85.2%) and particularly low Recall (63.6%) underscore persistent limitations in comprehensive occupant detection. In the slowdown dataset, both YOLO v5 and YOLO v8 continue to demonstrate strong performance, with mAP values of 96.4% and 96.8% respectively, and Accuracy rates above 95%. Their processing times remain impressively low, underscoring their efficiency in various data conditions. F-RCNN, while showing an improved mAP of 93.8% and Accuracy of 94.2%, continues to struggle with a low Recall rate (55.7%). YOLO v5 and YOLO v8 consistently outperform F-RCNN across different datasets in Zone 1, exhibiting superior mAP, Accuracy, and Recall, coupled with faster processing times.

Fig. 6 and Fig. 7 addresses occupant detection in Zone 2, comparing the same object detection methods across distinct datasets. YOLO v8 achieves the highest mAP of 78.3%, coupled with an Accuracy of 66.1% and Recall of 84.9% in the Original dataset. Compressed data still yields high mAP (84.1%) and Accuracy (82.9%), although Recall is slightly lower at 80.9%. YOLO v5 and F-RCNN exhibit varying performance metrics across datasets, emphasizing the dataset-dependent nature of these methods. In the Slowdown dataset, YOLO v8 maintains its superior mAP and Recall, highlighting its consistent performance.

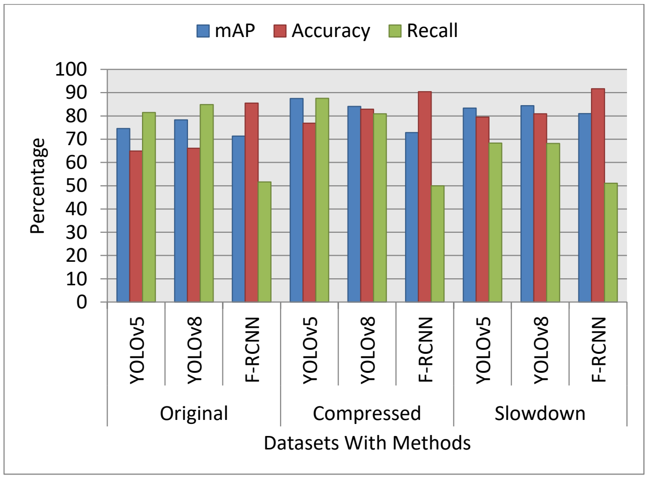

Fig. 6. Performance comparison of zone 2.

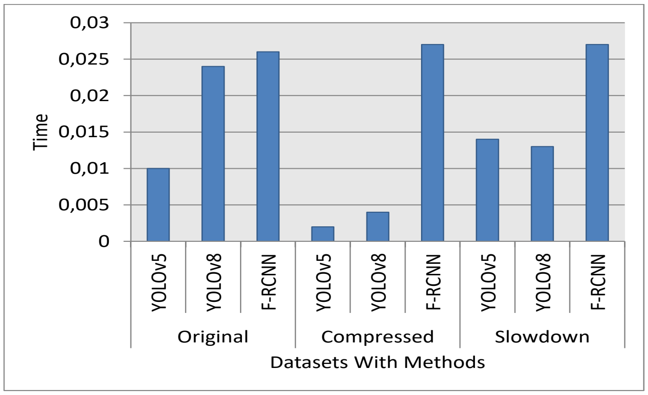

Fig. 7. Time process comparison of zone 2.

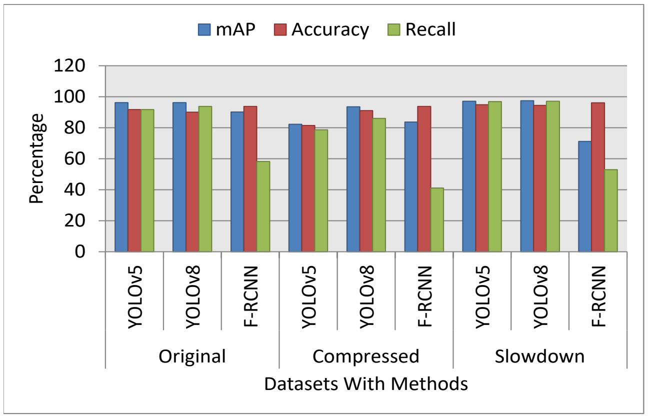

Fig. 8. Performance comparison of zone 3.

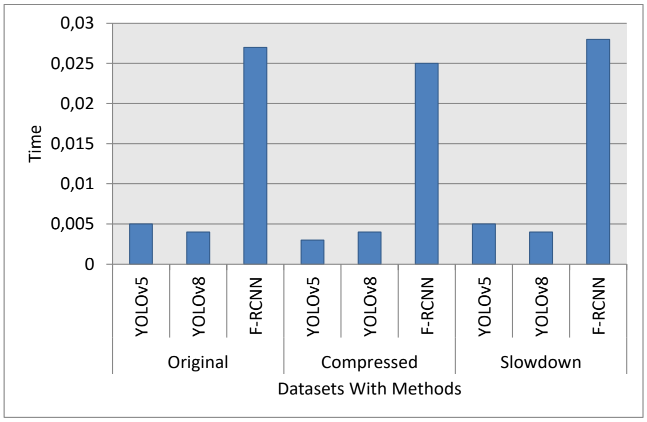

Fig. 9. Time process comparison of zone 3.

Fig. 8 and Fig. 9 focuses on Zone 3, where YOLO v5 and YOLO v8 continue to perform well in the original dataset, both YOLO v5 and YOLO v8 exhibit remarkably consistent and high-performance levels. They each achieve mAP of 96.2%, indicating a highly accurate ability to detect and identify occupants within this zone. Additionally, these methods demonstrate substantial Accuracy and Recall, reflecting their precision and reliability in correctly identifying true positives without missing significant detections. The analysis of the compressed dataset highlights the exceptional adaptability of YOLO v8. It achieves a notable mAP of 93.5%, maintaining high Accuracy and Recall rates despite the challenges posed by data compression. This performance suggests that YOLO v8 is particularly suited for scenarios where data integrity might be compromised or where bandwidth limitations necessitate data compression. In the context of the Slowdown dataset, both YOLO v5 and YOLO v8 continue to excel. They demonstrate robustness in mAP, Accuracy, and Recall, underscoring their effectiveness even under conditions that may affect the speed or flow of data input. Their high performance in this dataset is indicative of their ability to maintain reliability and accuracy in less-than-ideal operational environments. Faster R-CNN, while showing competitive performance in certain scenarios, does not consistently match the overall performance metrics of YOLO v5 and YOLO v8. This observation suggests that while F-RCNN can be effective in specific contexts, it may not be the optimal choice for all scenarios, particularly those represented in Zone 3.

In Zone 1, YOLO v8 achieves an outstanding mAP of 99.2%, indicating its high precision in detecting occupants. The Accuracy of 98.4% showcases its ability to correctly classify occupants, while the Recall of 98.6% demonstrates its capability to capture almost all actual occupants. Furthermore, YOLO v8 maintains a swift execution time of 0.004 seconds, indicating efficiency in processing. In Zone 2, YOLO v8 continues to demonstrate its efficacy with mAP of 78.3%, reflecting its strong performance in detecting occupants. The Accuracy of 66.1% suggests that it correctly classifies occupants in the zone. Moreover, the Recall of 84.9% underscores its ability to capture a significant portion of actual occupants. Despite a slightly longer execution time of 0.024 seconds compared to Zone 1, it remains efficient. Zone 3 further emphasizes the efficacy of YOLO v8, with mAP of 96.2% showcasing its precision in occupant detection. The Accuracy of 90.1% reflects its high classification accuracy, and the Recall of 93.7% indicates its ability to capture the majority of actual occupants. YOLO v8 maintains an efficient execution time of 0.004 seconds in this context. Overall, YOLO v8 demonstrates remarkable efficacy, consistently achieving high mAP values across all three zones, signifying precise occupant detection. Its competitive Accuracy and Recall values further validate its effectiveness. Additionally, its efficient execution times indicate that YOLO v8 combines both efficacy and efficiency, making it a strong candidate for occupant detection tasks in various scenarios.

B. Discussion

The study Occupancy Measurement in Under-Actuated Zones presents significant results in regards to the effectiveness of the YOLO v8 model in accurately detecting and quantifying occupants in difficult environments. The research, which was conducted through the compilation of a comprehensive dataset via video observations in the student corner room at Universitas Trilogi, demonstrates the superior performance of the YOLO v8 model in occupant detection, particularly in dynamic under-actuated zones with varying occupancy patterns and complex environmental conditions. The model's real-time detection capabilities, high accuracy in identifying occupants, and efficient object localization highlight its adaptability and robustness in diverse situations. The study's key findings include the model's ability to precisely identify and count occupants in real-time within the segmented zones of the student corner room, showcasing its spatial accuracy and object localization proficiency. The research's quantitative metrics, including mean Average Precision (mAP), Accuracy, Recall, and execution time, highlight the model's effectiveness in accurately identifying true positive detections while minimizing false positives and negatives. Additionally, the YOLO v8 model's swift execution time further emphasizes its efficiency in data processing and real-time results delivery. Overall, the research findings suggest that the YOLO v8 model has the potential to revolutionize occupant detection systems in under-actuated zones, offering a promising solution for optimizing occupancy monitoring and management in complex environments. The study lays the groundwork for future research and development in the field of object detection and occupancy measurement, specifically focusing on addressing the unique challenges presented by under-actuated zones. The results of this study provide valuable insights into the capabilities of the YOLO v8 model and its potential applications in various industries. The research findings are a significant contribution to the field of occupancy measurement and highlight the potential of the YOLO v8 model as a solution for optimizing occupancy monitoring and management in challenging environments. The study's results also suggest that the YOLO v8 model could be a useful tool for a variety of industries, including but not limited to, security, safety management, and facilities management. The research findings are a valuable resource for academics, researchers, and professionals working in the field of occupancy measurement and object detection.

V. CONCLUSION

This study presents a comprehensive evaluation of occupant detection methods across three distinct zones using YOLO v8. The quantitative analysis demonstrates the efficacy and efficiency of YOLO v8 in occupant detection tasks. In Zone 1, YOLO v8 exhibits exceptional performance with a high mAP of 99.2%, indicating precise detection. The Accuracy of 98.4% and Recall of 98.6% further underscore its effectiveness. Additionally, YOLO v8 maintains an efficient execution time of 0.004 seconds, making it a suitable choice for real-time applications. Zone 2 showcases YOLO v8's efficacy with a respectable mAP of 78.3%, suggesting robust occupant detection. Despite a lower Accuracy of 66.1%, the Recall of 84.9% demonstrates its ability to capture a significant proportion of actual occupants. YOLO v8's execution time of 0.024 seconds in this zone remains efficient. In Zone 3, YOLO v8 continues to perform effectively, achieving mAP of 96.2%, indicating precise detection. The Accuracy of 90.1% and Recall of 93.7% highlight its capability to classify and capture occupants accurately. YOLO v8's efficient execution time of 0.004 seconds makes it a valuable choice for this scenario. The results suggest that YOLO v8 is a robust and efficient method for occupant detection in various zones. Its high precision and competitive recall values make it a promising solution for real-world applications. Future work in this research can explore further optimization of YOLO v8 for occupant detection by considering different datasets and environmental conditions. Additionally, the integration of advanced deep learning techniques and hardware acceleration can enhance both the accuracy and speed of occupant detection systems. Further research can also focus on addressing challenges related to occlusions and multi-object tracking in complex scenarios, advancing the field of occupant detection in smart environments.

ACKNOWLEDGMENT

Thank to Indonesian Ministry of Education, Culture, Research and Technology for giving research funding and Universitas Trilogi for giving permission to use the library the object of research.

***Abstract*—Atmospheric light scattering encompasses intricate physical process, including diverse scattering mechanisms and optical parameters. Addressing the challenges posed by the computationally intensive task of deciphering this phenomenon, this study introduces an efficient real-time simulation strategy. The proposed approach employs a physics-driven atmospheric modeling, leveraging a unified phase function to emulate both Rayleigh and Mie scattering phenomena. The scattering integral is approximated and discretized using the concept of ray-marching to solve the scattering integral. Based on the characteristics of different light sources, accurate ray-marching lengths are determined, streamlining the computational trajectory of the light path. Additionally, the introduction of texture dithering enhances the randomness of the initial sampling positions. The Shadow Map algorithm is adeptly employed to generate shadow mapping textures, eliminating the need for light calculations within shadowed regions, thereby reducing the number of samples and computational workload. Finally, color synthesis is used to determine the rendering color of the atmosphere under various fog density conditions. Experimental results show that this approach significantly improves rendering efficiency, and achieves real-time rendering while maintaining a realistic light scattering effect compared with other advanced light scattering rendering methods.**

Keywords*—Light scattering; ray marching; jittered sampling; color synthesis; real-time rendering

I. Introduction

The real-time simulation of atmospheric light scattering is essential for enhancing the realism of virtual scenes [1]. In movies, games, and virtual reality applications, being able to render realistic skies, lighting effects, and weather conditions in real time is crucial for improving users' visual experiences and sense of immersion [2]. Moreover, efficient light scattering simulation also has a significant impact on scientific research in climate change, environmental monitoring, and the field of computer graphics [3].

Currently, the real-time rendering of atmospheric light scattering effects faces two major challenges: one is the high computational complexity, as it requires consideration of the propagation of light through the atmosphere and various parameters such as atmospheric density and scattering coefficients, which involve complex integral calculations; the other is insufficient real-time performance, particularly in large scenes, where even with GPU hardware acceleration, achieving satisfactory computational efficiency and rendering speed remains challenging [4].

In response to the aforementioned issues, we propose an efficient simulation method tailored for the scattering effects of various light sources' rays in the atmosphere. Building upon the physically-based integral solution for light scattering, the method approximates and discretizes the scattering integral, enhancing the ray-stepping algorithm and reducing the length of the computed light paths. Additionally, the Shadow Map algorithm is employed to generate shadow mapping textures, eliminating the need for lighting calculations within shadowed areas, thereby further reducing the number of sampling points. This approach aims to strike a balance between computational efficiency and rendering quality, maintaining realistic simulation effects while enhancing rendering performance to meet the demands of real-time rendering of light scattering. The main contributions of this research are the as follows:

- Enhanced Henyey-Greenstein phase function for Rayleigh and Mie scattering intensities, simplified single-scattering model, and efficient multiple scattering integral computation.
- Optimized Ray-Marching with novel down-sampling method for various light source scenarios, reducing samples while maintaining rendering quality, significantly improving efficiency.
- Enhanced scene realism and 3D effects with optimized ambient and sunlight gradient effects under various times and weather conditions, using scene blending techniques for realistic light scattering.

The paper is structured as follows. Section II reviews previous studies. Section III delves into the construction and optimization of light scattering models, introducing novel techniques and methods. Subsequently, it optimizes the sampling strategy for efficient rendering and presents our approach to atmospheric color synthesis. Section IV presents results and discussions. Finally, this paper concludes in Section V.

II. Related Work

The simulation of light scattering effects relies on the computation of light scattering integrals, which describe the physical phenomenon where light changes its direction of

*Corresponding Author.

propagation due to interactions with particles in a medium. This complex process involves principles of wave optics and variables such as the size, shape, and refractive index of the particles. In the field of computer graphics, light scattering is key to creating realistic lighting effects, particularly when rendering scenes involving fog, smoke, clouds, and other participating media.

To accurately mimic these visual effects, researchers and developers have employed a variety of scattering models that approximate the true scattering behavior. Some widely used theoretical models and methods include: Rayleigh scattering [5], Mie Scattering [6], Henyey-Greenstein Phase Function [7], Monte Carlo Method [8], Light scattering integrals in ray tracing algorithms [9] and so on. Each model and method have its own range of applicability and trade-offs, and the choice often depends on the desired level of accuracy, computational resources, and specific application scenarios.

Currently, optical scattering models in atmospheric scenes are primarily categorized into two main types: empirical models and physical models. Empirical models are typically derived from measurements and statistics of physical parameters such as the shape, size, and concentration of gas particles, in order to deduce the scattering and absorption characteristics of these particles towards light. Empirical models are usually suitable for scenarios with low gas particle concentrations and regular particle shapes. However, physical based models are more applicable for gas environments characterized by complex particle distributions, diverse compositions, or varying properties. Hillaire [10] introduced a novel method for real-time evaluation of multiple light scattering within the atmosphere. By introducing a set of simplified lookup tables and parametrization techniques, it aims to efficiently render skies and their aerial perspectives. This method enables dynamic variations in atmospheric composition to align with artistic visions and weather conditions, eliminating the need for cumbersome LUT updating processes.

To improve the rendering efficiency of atmospheric scattering effects, on the one hand, advancements in computer hardware performance have been leveraged. Modern Graphics Processing Units (GPUs) are utilized for parallel computation and optimized algorithms to accelerate calculation speeds [11]. On the other hand, approaches based on analytical formulae, numerical approximations, and pre-computation are applied to reduce the complexity of integral calculations in atmospheric scattering models, thereby improving computational efficiency. Huo et al. [12] presented an adaptive matrix column sampling and completion method to accelerate the rendering of participating media. However, this method could only handle single scattering scenarios and was not applicable for rendering participating media in dynamic scenes. In 2020, West et al. [13] introduced a novel method called Continuous Multiple Importance Sampling (CMIS) to solve the problem of multiple importance sampling in Monte Carlo integral estimation. This method improves the efficiency of rendering materials, including participating media.

In order to more realistically reproduce light scattering effects, significant progress has also been made in the study of multiple scattering. László et al. [14] improved the traditional light-medium interaction model, allowing control of the extinction coefficient and control variables through approximated sampled values, thereby enhancing rendering efficiency. In 2019, Vibert et al. [15] presented a new scalable hierarchical VRL method that preferentially samples VRLs according to their image contribution, yet this method requires further improvement for rendering anisotropic media. Deng et al. [16] proposed a novel unbiased volume density estimator, the photon surface, which is combined through multiple importance sampling to handle ray paths including single scattering and within-medium transmission. In 2021, Alexander et al. [17] introduced a fitting model for skylight radiance and attenuation in real land atmospheres, significantly enhancing the visual authenticity of existing analytical clear-sky models and the visual realism of interactive methods based on approximate atmospheric light transmission. In the same year, Kettunen et al. [18] proposed a method for improving the efficiency of unbiased volume transmittance estimators. This method reduces variance through various means, resulting in estimators with several orders of magnitude lower variance at the same computational cost, thereby improving the efficiency of ray marching. In 2022, Korkin et al. [19] extended the scope of previous research by considering the reflection of polarized light by a Rayleigh scattering spherical atmospheric layer with highly correlated single-scatter absorption rates. They employed three advanced radiative transfer models to generate numerical results, covering both single scattering and multiple scattering scenarios.

Despite significant advancements in the study of light scattering effects, further exploration is still needed on how to better balance high rendering quality with real-time requirements. In response to the efficiency challenges for rendering atmosphere light scattering, a real-time simulation method for the scattering effects of light in the atmosphere is proposed. This method utilizes approximate numerical calculations and down-sampling to effectively enhance rendering efficiency. Additionally, scene blending techniques are employed to improve the rendering color, resulting in a more realistic portrayal of light scattering effects in the atmosphere.

III. Modeling and Simulation Optimization Methods

A. Constructing Light Scattering Model

Light scattering in the atmosphere mainly occurs through two processes: Rayleigh and Mie scattering. Rayleigh scattering, caused by tiny particles like air molecules, is why the sky looks blue and red during sunrise and sunset. Mie scattering, from larger particles like water droplets and aerosol particles, makes clouds and fog appear white. Our model focuses on these two types of scattering.

The relationship between the intensity of Rayleigh scattering and the wavelength of incident light, as well as the scattering angle, is expressed as shown in Eq. (1):

$$I(\theta) = I_0 \frac{\pi^2 (n^2 - 1)^2 \rho(h)}{2N\lambda^4}(1 + \cos^2\theta) \tag{1}$$

Where $I(\theta)$ is the intensity of scattered light, λ is the wavelength of incident light, θ is the scattering angle, h is the height of the point, I_0 is the intensity of incident light, n is the refractive index of air, N is the density of air molecules at standard atmospheric pressure, $\rho(h)$ represents the relative density of air molecules at height h. When $h{=}0$, then $\rho(h){=}1$. From this, it can be seen that the intensity of Rayleigh scattering is inversely proportional to the fourth power of the wavelength of the incident light. In other words, shorter wavelengths result in stronger scattering. In optics, the phase function is commonly used to describe the scattering properties of light as it interacts with materials. Since Rayleigh scattering is nearly isotropic, meaning that light is scattered uniformly in all directions by particles, its phase function is shown in Eq. (2):

$$F_R(\theta) = \frac{3}{16\pi}(1+\cos^2\theta) \quad . \tag{2}$$

In our model, approximate calculations are performed for Mie scattering, with extinction coefficients and asymmetry factors pre-computed. Combined with the improved Henyey-Greenstein phase function, Rayleigh scattering and Mie scattering can be uniformly described.

In the atmosphere, larger particles interfere with the light collected at the observation point. At this point, the light mapped to the observation point mainly comes from two parts: the light from target reflection attenuated by particles and reaching the observation point, and the atmospheric light formed by light source scattering through particles. Therefore, based on light energy transmission, an atmospheric scattering illumination model is constructed, and the total radiation rate received at point x is shown in Eq. (3):

$$I_c(x,\omega) = I_0(x,\omega)\mathrm{e}^{-\int_0^x \beta_{ex}(x')\mathrm{d}x'} + \int_0^x g(x,\omega)\mathrm{e}^{-\int_{x'}^x \beta_{ex}(x'')\mathrm{d}x''}\mathrm{d}x' \tag{3}$$

Where ω is the incident direction, $I_c(x,\omega)$ is the outgoing light intensity at position *x*, $I_0(x,\omega)$ is the incident light intensity at position *x*, β_{ex} is the extinction coefficient, and $g(x,\omega)$ is the scattering distribution intensity at position *x*. The first part of this equation represents the intensity of light transmitted directly from the light source to the observation point, taking into account the absorption attenuation of light. The second part represents the scattering process through the medium, considering the scattering attenuation of light.

Eq. (4) represents the sum of light intensity scattered from direction ω at point *x*, where the rays from different directions ω_i interact with the medium at that location.

$$g(x,\omega) = \beta_{sc}\int_{4\pi} I(x,\omega_i)F(\omega,\omega_i)\mathrm{d}\omega_i \tag{4}$$

Where $\beta_{sc}{=}\beta\rho$ is the scattering coefficient, β is a tunable parameter, ρ represents the atmospheric density ratio to simulate atmospheric density, $I(x,\omega_i)$ is the incident light intensity from ω_i, and $F(\omega,\omega_i)$ is the phase function of the scattering medium. The angle between ω and ω_i is denoted as θ, which is the scattering angle. Therefore, the phase function can be expressed as $F(\theta)$.

Since this incident intensity is a collection of light emitted from various directions in the sky domain and lacks a specific directionality as a whole, a unified phase function can be applied here. Due to the complexity of the true physical functions for Rayleigh and Mie scattering, using an approximation for the phase function $F(\theta)$ can significantly reduce computational complexity. The directional characteristics of the scattering model vary with particle size. Unlike Rayleigh scattering, the direction of Mie scattering is anisotropic, where light is more scattered forward. Different scattering characteristics can be constructed by combining various linear phase functions and adjusting the values of the asymmetry factor. The Henyey-Greenstein phase approximation function is shown in Eq. (5):

$$F(\theta) = \frac{(1+\cos^2\theta)}{(1+g^2-2g\cos(\theta))^{3/2}} \tag{5}$$

Where g is the asymmetry factor. However, this phase function can only describe forward scattering and cannot accurately simulate the effects of backward scattering. To address this issue, an improved Henyey-Greenstein phase function, as shown in Eq. (6), was adopted to achieve the simulation of backward scattering while avoiding the introduction of excessive complexity coefficients.

$$F(\theta) = \frac{1}{4\pi}\frac{3(1\text{-g}^2)}{2(2+g^2)}\frac{(1+\cos^2\theta)}{(1+g^2-2g\cos(\theta))^{3/2}} \tag{6}$$

The value range of *g* is [-0.75, 0.99]. When *g* is negative, it corresponds to forward scattering, and when g is positive, it corresponds to backward scattering. When the g-value is 0, it results in isotropic scattering, which manifests as Rayleigh scattering.

B. Simplified Integral Solution and Multiple Scattering

During the propagation of light, particles in the air cause scattering of the light. When there are fewer particles in the air, light is usually scattered only once. However, in an atmosphere with a lot of larger particles, the scattered light may continue to be scattered by other particles, resulting in a multiple scattering effect. In conditions where the air quality is poor, multiple scattering can significantly affect our perception of the scene. Computing multiple scattering is complex as it involves extensive integration calculations, making real-time rendering challenging. To address this issue, one can utilize the fact that within a certain area, the variation in particle concentration is typically gradual. Therefore, it's not necessary to calculate the scattered light intensity for every single particle; instead, one can compute the scattered light intensity of some particles along the line of sight to represent the whole.

The specific method, as shown in Fig. 1, involves dividing the air space through which the line of sight passes into several segments, taking the average concentration of like particles within each segment. This allows for segmented sampling based on the variations in atmospheric particle concentration and incident light intensity with distance. The size of each segment needs to be determined by considering the changes in both atmospheric particle concentration and incident light intensity to ensure they remain roughly constant within each segment. The number of segments can be adjusted based on the required drawing precision. This method avoids point-by-point sampling along the line of sight, thereby significantly reducing the computational load.

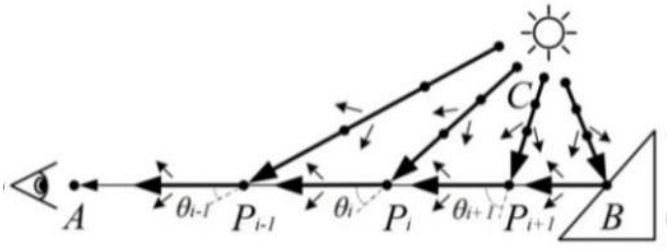

Fig. 1. Schematic diagram of scattered light intensity calculation.

Uniformly select N sampling points along the path AB, denoted as $P_1, P_2 \ldots\ldots P_N$. The total light intensity scattered into the viewer's eye along the line of sight is the sum of particle-scattered light intensities from N sampling segments along the line of sight. After these simplifications, Eq. (3) can be simplified to Eq. (7).

$$I_c = \sum_{i=1}^{N} I_c^i \tag{7}$$

Similarly, when calculating the attenuation coefficient along path CP_i, sampling is also required, with the number of selected points denoted as M. The more sampling points there are, the closer the result is to Eq. (3). However, having too many sampling points can impact real-time performance, necessitating a careful balance. Therefore, Eq. (3) can be discretized into a summation form to significantly simplify the computational complexity, as shown in Eq. (8) and Eq. (9).

$$I_c^{(\upsilon)}(x,\omega) \approx I_0^{(\upsilon)}(x,\omega)\prod_{i=1}^{N} \mathrm{e}^{\beta_{\mathrm{ex}i}^{(\upsilon)}\Delta x} + \sum_{i=1}^{N} g(x,\omega)\prod_{j=i+1}^{N} \mathrm{e}^{\beta_{exj}^{(\upsilon)}\cdot\Delta x} \tag{8}$$

$$g(x,\omega) \approx \sum_{i=1}^{M} I_i^{(\upsilon)} \beta_i^{(\upsilon)} F^{(\upsilon)}(\theta) \tag{9}$$

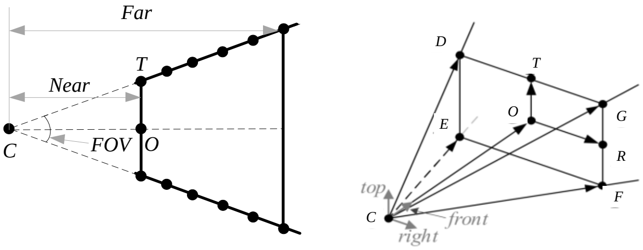
where υ represents the number of multiple computation iterations, N signifies the count of particles with different scattering properties, and M denotes the surrounding voxels that have already been calculated.

Ray-Marching is a ray stepping technique that works by shooting rays from the viewpoint and advancing them step by step, calculating the distance to the surface of objects at each step until a predefined termination condition is met. Its advantages over other methods lie in its ability to achieve extremely smooth effects and handle complex geometries. Rendering performance can be improved by reducing the calculated length of light paths, decreasing the number of samples, and avoiding the computation of unnecessary sample points.

C. Reducing the Length of Ray Marching

When using Ray-Marching for rendering, it's generally assumed to start from the camera position and sample along rays emanating from it until the ray reaches the camera's far clipping plane or intersects with an object. Lighting is a necessary condition for scattering, so it's only necessary to perform ray marching sampling within the range of the lighting. There's no need to march rays throughout the entire scene, which can help reduce the length of the calculated sampling path and improve rendering efficiency. However, different light sources possess varying lighting ranges and other characteristics.

1) Directional Light Ray Marching Path: Rays emitted by directional light sources are mutually parallel, and the illumination can cover the entire scene. Therefore, ray marching needs to take place between the camera's near clipping plane and far clipping plane. The starting point of the ray can be adjusted from the camera's position to its near clipping plane. The position of this new starting point can be determined by the geometric relationship between the camera and the near clipping plane, as shown in Fig. 2.



(a) Directional light ray marching range (b) The relative position of the camera and the near clipping plane

Fig. 2. Schematic diagram for calculating the distance between each point on the near clipping plane and the camera.

In Fig. 2(a), *FOV* represents the opening angle of the visual cone in the vertical direction, *Near* and *Far* respectively indicate the distance from the camera to the near clipping plane and the far clipping plane. In Fig. 2(b), the plane DEFG is the near clipping plane. $\overrightarrow{top}$, $\overrightarrow{right}$ and $\overrightarrow{front}$ represent the camera's upward, rightward, and forward directions. From this, the vectors to the four corner points of the near clipping plane from the camera can be obtained as shown in Eq. (10)-Eq. (13).

$$\overrightarrow{CD} = \overrightarrow{CO} + \overrightarrow{OT} - \overrightarrow{OR} \tag{10}$$

$$\overrightarrow{CE} = \overrightarrow{CO} - \overrightarrow{OT} - \overrightarrow{OR} \tag{11}$$

$$\overrightarrow{CF} = \overrightarrow{CO} - \overrightarrow{OT} + \overrightarrow{OR} \tag{12}$$

$$\overrightarrow{CG}=\overrightarrow{CO}+\overrightarrow{OT}+\overrightarrow{OR} \tag{13}$$

The current camera's aspect ratio is *Aspect*. Based on the positions corresponding to the sampling points in Fig. 4, $\overrightarrow{CO}$, $\overrightarrow{OT}$, and $\overrightarrow{OR}$ can be obtained as shown in Eq. (14)- Eq. (16).

$$\overrightarrow{CO}=\overrightarrow{front}\cdot Near \tag{14}$$

$$\overrightarrow{OT}=\overrightarrow{top}\cdot\left|\overrightarrow{OT}\right|=\overrightarrow{top}\cdot(Near\times\tan\frac{FOV}{2}) \tag{15}$$

$$\begin{aligned}\overrightarrow{OR}&=\overrightarrow{right}\cdot(\left|\overrightarrow{OT}\right|\times Aspect)\\&=\overrightarrow{right}\cdot(Near\times\tan\frac{FOV}{2}\times Aspect)\end{aligned} \tag{16}$$

Substituting Eq. (14)-(16) into Eq. (10)-(13), the computed results are passed to the vertex shader in the form of three-dimensional vectors. The rendering pipeline will automatically interpolate these vectors for each fragment. Subsequently, in the fragment shader, the interpolated vectors can be used to calculate the ray starting point corresponding to each pixel.

2) Point Light Ray Marching Path: Unlike directional light, the illumination range of a point light source is localized and forms a sphere. The actual effective range for ray marching is the intersection between the ray and the lighting sphere. As shown in Fig. 3.

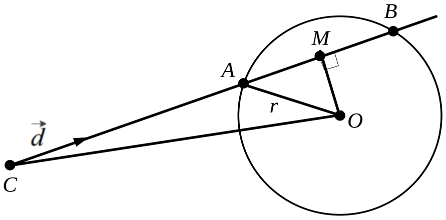


Fig. 3. Analysis of Intersection between light and point light sphere.

The ray emitted from point *C* intersects the sphere with radius *r* and center *O* at points *A* and *B*, where $\vec{d}$ is the unit vector representing the ray direction. According to the definition of vector dot product, the length of the line segment CM is given by Eq. (17), and the square of the length of AM is given by Eq. (18).

$$\left|\overrightarrow{CM}\right|=\vec{d}\cdot\overrightarrow{CO} \tag{17}$$

$$\left|\overrightarrow{AM}\right|^2=r^2-\left|\overrightarrow{OM}\right|^2=r^2-(\left|\overrightarrow{CO}\right|^2-\left|\overrightarrow{CM}\right|^2)\ . \tag{18}$$

According to Formulas (17) and (18), it can be deduced that the intersection point vector between the ray and the point light source's sphere is given by Eq. (19).

$$\begin{cases}\overrightarrow{CA}=\overrightarrow{CM}-\overrightarrow{AM}=(\vec{d}\cdot\overrightarrow{CO}-\sqrt{r^2-(\overline{\overrightarrow{CO}-\vec{d}\cdot\overrightarrow{CO}\cdot\vec{d}})\cdot\overrightarrow{CO}})\cdot\vec{d}\\\overrightarrow{CB}=\overrightarrow{CM}+\overrightarrow{AM}=(\vec{d}\cdot\overrightarrow{CO}+\sqrt{r^2-(\overline{\overrightarrow{CO}-\vec{d}\cdot\overrightarrow{CO}\cdot\vec{d}})\cdot\overrightarrow{CO}})\cdot\vec{d}\end{cases} \tag{19}$$

From this, the starting and ending positions for the ray marching can be determined.

3) Spotlight Ray Marching Path: Similar to point lights, spotlights also have a localized lighting range and exhibit a conical shape, as shown in Fig. 4.

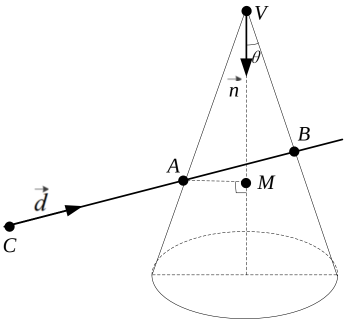

Fig. 4. Analysis of intersection between light and spotlight cone.

The rays emitted from point *C* intersect the cone at points *A* and *B*. Where $\vec{d}$ and $\vec{n}$ are both unit vectors representing the directions of the ray and the axis of the cone, respectively. θ is the angle between the axis of the cone and the generatrix. Therefore, the vector from point *C* to the intersection points between the ray and the cone can be expressed as shown in Eq. (20).

$$\overrightarrow{CA}=t\vec{d} \tag{20}$$

where *t* is the parameter along the ray. Based on the relationships in Fig. 6, Eq. (21) and Eq. (22) can be derived as follows:

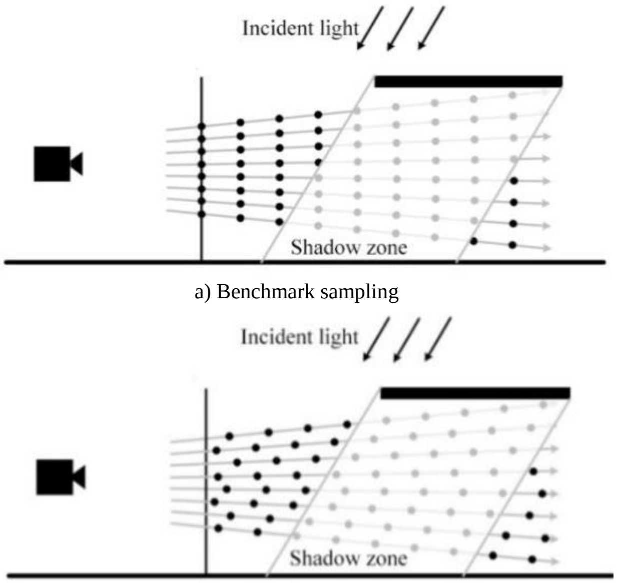
$$\overrightarrow{VA}\cdot\vec{n}=\left|\overrightarrow{VA}\right|\cdot\left|\vec{n}\right|\cdot\cos\theta=\left|\overrightarrow{VA}\right|\cdot\cos\theta \tag{21}$$

$$\overrightarrow{VA}=\overrightarrow{VC}+\overrightarrow{CA} \tag{22}$$

By substituting Eq. (20) and Eq. (22) into Eq. (21) and solving, we can obtain the parameter *t* at which the ray intersects with the lighting cone, thus obtaining the coordinates of intersection point *A*. Similarly, the coordinates of intersection point *B* can be obtained. It's worth noting that due to light attenuation or obstruction by objects, the lighting cone has a certain height limitation. If the height of the lighting cone is set to *h*, it can be determined whether there is an intersection between the ray and the lighting cone by evaluating $0\le\left|\overrightarrow{VA}\right|\cos\theta\times h\le h$.

D. Reducing Sampling Number

During ray marching, increasing the number of sampling can lead to lower simulation efficiency. Therefore, minimizing the number of samples is crucial. However, excessively reducing the sample count may result in noticeable artifacts or banding in the image, significantly affecting realism. This is because larger intervals between sampling points fail to capture sufficient lighting information. From an image processing perspective, this issue belongs to quantization errors and can be mitigated by using dithering. Texture dithering introduces a certain level of randomness in atmospheric light scattering simulations to replicate the complex variability of atmospheric lighting phenomena in the real world. Due to the non-uniform distribution of atmospheric particles in the actual environment, light scattered by these particles creates a natural, seemingly random effect visually. By applying subtle random noise to the image, texture dithering achieves random offsets corresponding to screen pixels, breaking up the regular patterns that quantization errors might otherwise introduce. This method enhances the randomness of sampling points, not only improving the realism of simulated scenes but also optimizing rendering performance without increasing additional computational burden.



a) Benchmark sampling

b) Jittered sampling

Fig. 5. Comparison of benchmark sampling and jitter sampling.

Using the sampling starting positions calculated in Section 4.1 as a reference, Fig. 5(a) depicts the benchmark sampling where the offset is 0. Fig. 5(b) shows the jitter sampling, which adds a random offset on the benchmark starting sampling position, allowing the sampling points between different rays to be staggered. It is worth noting that the random offset should be less than the step size value of the ray marching.

Jittered sampling effectively transforms the color band resulting from reducing the sampling count into noise point in the image. Common methods for generating jitter maps are based on Bayer matrix, white noise, and blue noise. Fig. 6 shows the sampling results under different jitter textures.

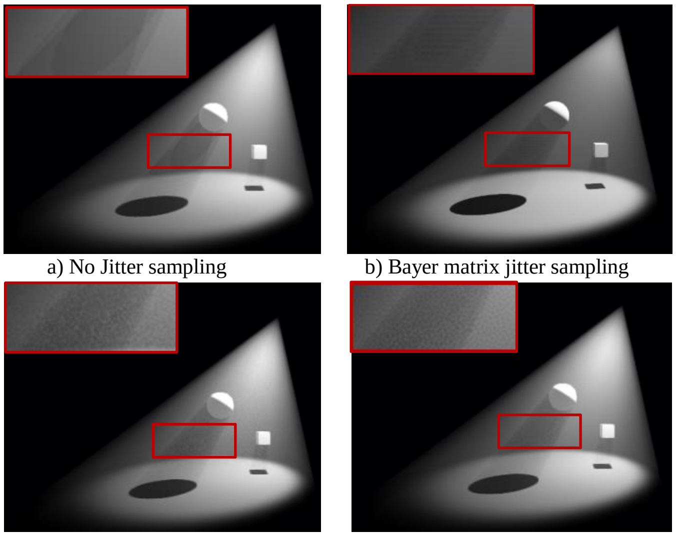
When the sampling count is set to 15, due to the limited number of samples, there will be significant banding distortion at the shadow without using the jitter sampling method, as shown in Fig. 6(a). The jitter texture generated using the Bayer matrix has strong regularity and generates duplicate lattice points, as shown in Fig. 6(b). The white noise jitter texture generates more noise points, resulting in poor performance, as shown in Fig. 6(c). The results generated using blue noise jitter textures exhibit relatively fewer noise points and higher randomness, which is beneficial for subsequent blur processing, as shown in Fig. 6(d). In comparison, the image quality generated by blue noise is better. Therefore, using blue noise to generate jitter textures is recommended. After jitter sampling, the generated noise can be removed using a Gaussian bilateral blur method, while preserving the clear contours of the image. The Gaussian bilateral blur weights of pixels are calculated as shown in Eq. (23).

$$\omega_i(x_i,d_i)=\frac{1}{\sigma\sqrt{2\pi}}\exp(-\frac{x_i^{2}}{2\sigma^{2}}-d_i^{2}) \tag{23}$$

The color contribution value of the *i*-th pixel with a relative distance of x_i and a relative depth of d_i from the target pixel can be obtained by Eq. (23).

Where σ is the standard deviation, and the larger the value, the stronger the blurring effect. These weights need to be normalized before it can be used. The normalized pixel weights are computed as shown in Eq. (24).

$$\varpi_i(x_i,d_i)=\frac{\omega_i(x_i,d_i)}{\sum_{i=1}^{N}\omega_i(x_i,d_i)} \tag{24}$$



a) No Jitter sampling

b) Bayer matrix jitter sampling

c) White noise jitter sampling

d) Blue noise jitter sampling

Fig. 6. Comparison of rendering effects of different jitter textures.

E. *Reduce the Range of Lighting Calculation*

During the process of ray marching, some sampling points might be situated within shadows, as shown in Fig. 5. These sampling points within shadows do not contribute to scattering light. If we can quickly determine whether a sampling point is in shadows, it would help reduce computational workload and enhance simulation efficiency.

Shadow Map is a simple and fast shadow rendering algorithm, which means that when viewed from the position of the light source, all visible objects are illuminated by the light source, and all occluded and invisible objects are in shadow. Firstly, the light source is treated as the camera to render the entire scene and obtain the depth of each object. This depth information is then saved as a texture, which is referred to as the shadow mapping texture. Next, the scene is rendered using the camera's perspective, obtaining vertex coordinates. Transforming these vertices into the light source's coordinate space yields their clipping coordinates (x, y, z) within that space. By utilizing the transformed vertex coordinates (x, y), a sampling of the shadow mapping texture provides the maximum depth value z' for the illumination. If $z< z'$, then the vertex is in the shadow, otherwise it is not in the shadow.

By utilizing the Shadow Map, we can quickly determine whether each sampling point is in shadow. For points within shadows, light intensity calculations can be skipped, as their radiance is considered to be zero since they do not contribute to the final scattered light intensity, effectively reducing the number of sampling points for which light computations are required, thus significantly enhancing rendering efficiency.

F. Improving the Ray Marching Rendering Algorithm

Compared to the traditional Ray-Marching algorithm, the improved Ray-Marching rendering algorithm enhances sampling efficiency, and its pseudo code is shown in Algorithm 4.1.

Algorithm 4.1 Improved Ray Marching Rendering Algorithm:

Input: Pixel information X, Number of ray marching samples N, Light source color Ic

Output: Color corresponding to pixel points

```
Function ImprovedRayMarching(X, N, Ic):
W = CalculateWorldCoordinates(X)
StartPoint = CalculateStartPoint(W)
R = ApplyJitterSampling(StartPoint)
S = GetStepSize(R, N)
I = 0
For i = 1 to N:
        If InShadowRegion(R):
            Continue
        End If
        Ii = CalculateIncidentLightIntensity(R)
        ρ = CalculateFogDensity(R)
        I0 = CalculateScatteredLightIntensity(Ii, ρ)
        I += I0
End For
Pc = Ic * I
Return Pc
End Function
```

When performing atmospheric rendering based on the improved Ray-Marching approach, the initial stage involves recalculating the starting position and step size for ray marching along the direction of rays emitted from the camera. Additionally, jittered sampling is applied along the ray direction. If a ray intersects with an object, its advancement is halted, and distance information is returned. Furthermore, the sampled data and coverage information are utilized to calculate the atmospheric density. Subsequently, the computation of fog area shadows is performed. Rays situated within the shadowed region do not necessitate scattering calculations, and efficiency can be enhanced by excluding these rays. Afterward, atmospheric color values are sampled at the current ray position, and a scene shadow map is generated. This shadow map is then stored in the command buffer for later storage in a texture. Then, it's combined with sunlight and ambient light colors. In addition, lighting calculations are necessary, including extinction coefficient, scattering contribution, and transmittance, among others. After completing these calculations through iterative processes, the final atmospheric color is generated.

G. Atmospheric Color Synthesis

In order to enhance the representation of lighting details, the light scattering effect in fog is simulated using scene blending techniques. Ambient light, as diffused rays, pervades the entire scene and traverses through dynamically changing fog regions. The fog is denser near the ground, resulting in deeper colors. The ambient light generated based on height and time will influence the color of the fog region. Here, a negative cosine function curve is introduced and the time difference range is extended to $[0,\ 2\pi]$. The ambient light color for different heights and times is obtained by multiplying with the ratio of the height field, calculated as shown in Eq. (25).

$$C_{\text{amb}} = \left[\frac{H_{\text{cur}}}{2H_{\text{total}}} \cdot (1-\cos((\frac{T_{\text{cur}}-T_{\text{start}}}{T_{\text{end}}-T_{\text{start}}}) \cdot 2\pi))C_{\text{inc}} + C_{\text{stan}} \right] \tag{25}$$

Where $H_{\text{cur}} / 2H_{\text{total}}$ represents the height field ratio, T_{cur} is the current time, thus the range of $(T_{\text{cur}}-T_{\text{start}})/(T_{\text{end}}-T_{\text{start}})$ is [0, 1], C_{inc} is the incremental color, and C_{stan} is the standard ambient light color. The color and position of sunlight dynamically change with time. Therefore, the corresponding color domain is defined, and the current color value of sunlight is obtained through interpolation based on the time ratio, as shown in Eq. (26).

$$C_{\text{sun}} = [\frac{T_{\text{cur}}-T_{\text{start}}}{T_{\text{end}}-T_{\text{start}}} \cdot C_0 + (1-\frac{T_{\text{cur}}-T_{\text{start}}}{T_{\text{end}}-T_{\text{start}}}) \cdot C_{\text{s-end}}](V_{s\to f} \cdot V_{v\to f}) \tag{26}$$

Where C_0 is the starting value of the sunlight color domain, $C_{\text{s-end}}$ is the ending value of the sunlight color domain, $V_{s\to f}$ represents the vector from the sun to the center of the fog, and $V_{v\to f}$ is the vector from the vertex to the center of the fog.

On the other hand, employing the Alpha blending technique with translucent textures enhances the realism of the fog. To further improve real-time performance, a distance threshold *l* is set to divide the rendering range. Particles within the threshold *l* are only rendered with the particle fog color, while those beyond the threshold *l* exhibit varying lighting effects using UV gradient animation and BillBoard techniques. As shown in Eq. (27):

$$C_{final} = \begin{cases} C_{\text{fog}} & d < l \\ (1-\alpha)\cdot(C_r + C_{\text{sun}} + C_{\text{amb}}) + \alpha\cdot C_{\text{fog}} & d \ge l \end{cases} \tag{27}$$

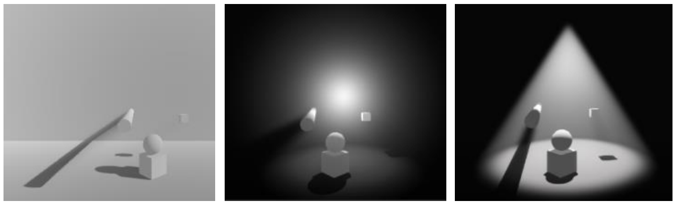
where C_{final} represents the blended rendered color, C_r is the fragment scene color, C_{fog} is the fog color, α is the blending coefficient, which is used to control the degree to which the fog color is influenced by the light.

IV. Discussion and Analysis of Results

To validate the effectiveness of the real-time rendering algorithm for light scattering effects proposed in this paper, simulations of atmospheric light scattering were conducted using Unity. The rendering quality and efficiency of the algorithm were demonstrated, and its performance was evaluated across multiple test scenarios by fine-tuning various algorithmic parameters to assess its robustness in different settings. The experimental environment of the testing platform includes the following hardware components: Intel(R) Core (TM) i7-5820K CPU @3.30 GHz, 16 GB RAM, and the graphics processor is NVIDIA GeForce GTX 1060. The main software used includes OS: Windows 10 (64 bit), development platform: Unity 3D engine, Visual Studio 2017, and the combination of C # scripting language and CG/HLSL shading language to design and render different scenes.

A. Comparison of Scattering Effects under Different Light Sources

The sampling range for ray marching varies under different light sources. Rendering the scene at a resolution of 1280×720 with the same sampling rate, Fig. 7 shows the scattering effects generated under different light sources.



(a) Directional light (b) Point light (c) Spotlight

Fig. 7. Comparison of light scattering effects under different light sources.

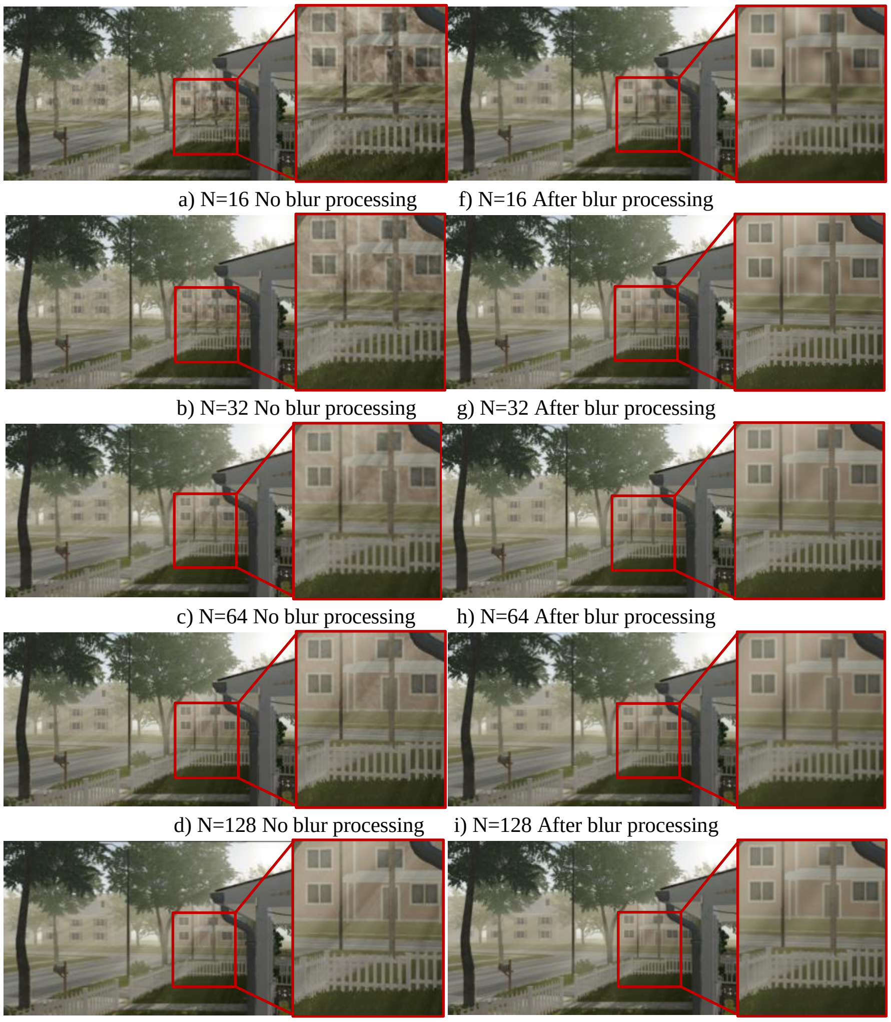
Fig. 7(a) shows a directional light that generates light scattering throughout the entire visual space. When using the traditional ray marching algorithm, the average rendering efficiency is 76.4 FPS. However, with the method proposed in this paper, rendering efficiency has improved to 89.5 FPS, representing a performance increase of 17%. Fig. 7(b) represents a point light source, with its scattering range forming a spherical shape. Fig. 7(c) shows a spotlight, generating a cone-shaped scattering range. Due to their radiation characteristics, point lights and spotlights require more ray sampling to capture variations of light in different directions. Because the scattering range of light in this scene is relatively concentrated, rendering efficiency demonstrates a slight improvement.

B. Comparative Analysis of Rendering Effects with Different Sample Counts

Fig. 8 shows a comparison of volumetric lighting rendering effects in the small town scene with different sample counts (N).

Fig. 8(a)-(e) shows the volumetric lighting rendering effects without Gaussian bilateral blur processing, while Fig. 8(f)-(j) shows the volumetric lighting rendering effects for the corresponding sample counts after the application of blur processing. In 1920×1080 resolution, when the sample count is low, as shown in Fig. 8(a) and 8(b), a lack of sufficient lighting information leads to the presence of numerous artifacts in the scene and the absence of beam effects. Upon applying the blur processing, extensive light spots are formed within the lighting area, as shown in Fig. 8(f) and 8(g). This results in significant distortion of the volumetric lighting rendering effect in the scene. As the number of samples increases, as shown in Fig. 8(c), the lighting area begins to exhibit noticeable beam effects, although some noise points still exist. With further increase in sample counts, more lighting information is gathered, resulting in a more refined and realistic beam effect. When the sample count reaches 256, the generated beam effect becomes quite realistic, as shown in Fig. 8(e). After blur processing, it can be observed that when the sample count reaches 64, the rendered lighting effect appears highly realistic. The beam boundary transition is natural, and the result is very close to the rendering achieved with higher sample counts, as shown in Fig. 8(h)-(j). This implies that, for practical purposes, the rendering effect achieved with a sample count of 64, enhanced by the blur process, can effectively substitute for higher sample counts. The rendering frame rates for different sample counts are shown in Table I. Increasing the sample count enhances rendering quality, but it also raises computational costs. In this complex scene, the rendering efficiency with 64 samples and blur processing can reach 46.4 FPS, which is 82% higher than the rendering efficiency without blur processing with 256 samples.

Therefore, our approach is able to achieve a more efficient and artifact-free realistic atmospheric lighting effect with fewer samples, achieving a balance between the desired visual quality and performance.



a) N=16 No blur processing f) N=16 After blur processing

b) N=32 No blur processing g) N=32 After blur processing

c) N=64 No blur processing h) N=64 After blur processing

d) N=128 No blur processing i) N=128 After blur processing

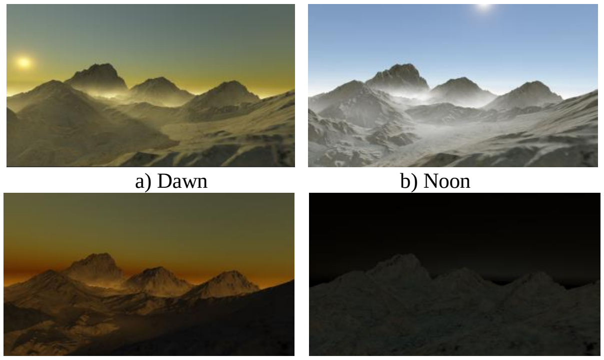
e) N=256 No blur processing j) N=256 After blur processing

Fig. 8. Comparison of volume light rendering effects with different sample counts.

C. Time-Varying Ray Scattering Effect

Fig. 9 shows the comparison of light scattering effects in non-uniform media that dynamically vary with the position of the sun.

Fig. 9(a) and (c) respectively show the light scattering effect under dynamic mountain fog in the morning and after sunset. At these times, the sun is near the horizon, and the sunlight enters the atmosphere at an oblique angle. This leads to significant scattering of blue light along the transmission path, preventing it from reaching the camera. As a result, the closer to the ground, the sky appears orange- yellow or orange-red. Fig. 9(b) shows the scene at noon, where the sky displays a gradient blue due to Rayleigh scattering. However, a noticeable mist-like effect is observed near the ground due to Mie scattering, significantly enhancing the realism of the entire scene. Fig. 9(d) shows the scene at midnight, without considering the influence of light from other celestial bodies, presenting a completely dark effect.



a) Dawn b) Noon

c) After sunset d) Midnight

Fig. 9. Comparison of time-varying light scattering effects in non-uniform media.

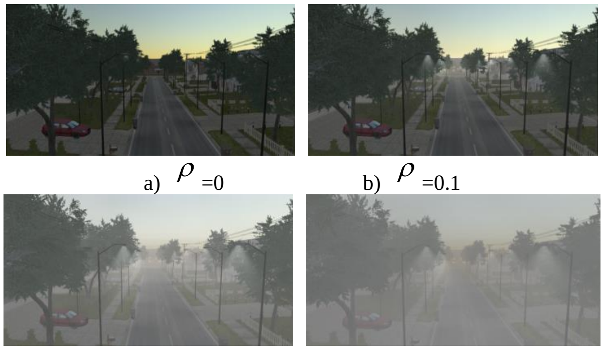
This indicates that the proposed method can effectively present dynamic light scattering effects caused by varying solar positions, enhancing the realism of the rendered scenes. Moreover, it can maintain a rendering efficiency of over 45FPS, meeting real-time requirements.

D. Rendering Effects for Different Atmospheric Density Ratios

The concentration of aerosol particles significantly affects the propagation, color, and intensity of light. Due to the fact that most air pollutants belong to aerosol particles, the intensity of Mie scattering can be affected by adjusting the atmospheric density ratio, thereby simulating the light scattering effect under different air qualities.

Fig. 10(a) presents the lighting scene of an urban street in the early morning, where the atmosphere does not contain aerosol particles. As a result, only the Raleigh scattering effect is evident in the distant sky, and there is no Mie scattering effect near the ground. The light from street lamps is primarily concentrated near the light sources, and there is no noticeable scattering effect. In Fig. 10(b), ρ=0.1, the lighting scene under good air quality is shown. In this case, the Mie scattering effect is evident near the ground. Fig. 10(c) and Fig. 10(d) respectively show the light scattering effects for conditions with ρ=0.3 and ρ=0.5. In both cases, the entire scene is covered by fog, with street lamps forming light beams within the fog.

As the atmospheric density ratio increases, the light scattering effects gradually enhances. The clarity and visibility of objects in the scene significantly diminish, and the sky gradually appears gray blue, in complete accordance with the physical principles of light scattering. This notably enhances the scene's depth and layering, and effectively elevating the realism of light scattering simulation under various levels of atmospheric pollution.



a) ρ =0 b) ρ =0.1

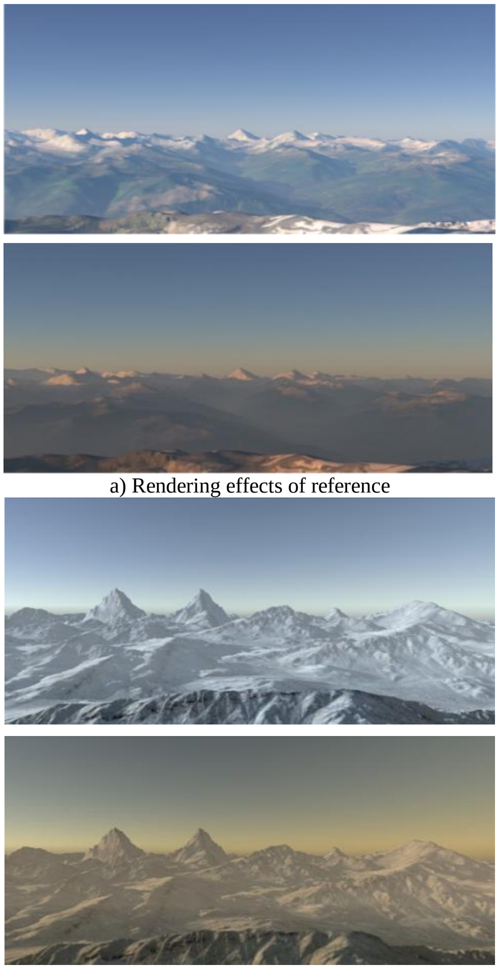
c) ρ =0.3 d) ρ =0.5

Fig. 10. Comparison of light scattering effects under different atmospheric density ratios.

E. Experimental Comparison and Results

Fig. 11 shows the comparison of light scattering effects between this paper and reference [17] in mountain scenes under clear skies.

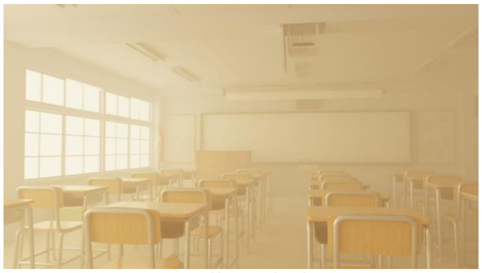
Fig. 11(a) illustrates the rendering results achieved by the method used in literature [17], which is based on an extensive atmospheric scattering dataset. This technique employs data fitting to reduce the size of the dataset and attain high-quality rendering effects. Despite its ability to produce images with a high degree of realism, the method's substantial demand for computational resources and storage space limits its applicability in real-time rendering scenarios. In contrast, Fig. 11(b) presents the light scattering effects realized in large-scale scenes using the method proposed in this paper. By adopting the same solar elevation angle as in literature [17], with the top image set at 15 degrees and the bottom image at 2 degrees, our method achieves visually realistic results comparable to those in literature [17]. Meanwhile, the average rendering frame rate of our method reached 43.6 FPS, fulfilling the requirements for real-time performance. The Mie scattering effect is not obvious in the near area, while it becomes more evident in the far area. This results in clear visibility of objects in the foreground and a gradual blurring and fading of objects in the distance, in accordance with the natural physics of light. Furthermore, as the elevation increases, the Mie scattering effect gradually weakens. And after reaching a certain height, it can still maintain a clear sky color, effectively achieving a realistic light scattering effect under a clear sky. It is worth noting that the frame rate of this method can reach 43.6 FPS, fully meeting the requirements of real-time rendering. In conclusion, our approach significantly improves rendering efficiency while maintaining light scattering effects comparable to those in reference [17]. This not only meets the requirements for real-time rendering but also satisfies the demands of applications with high real-time performance requirements.



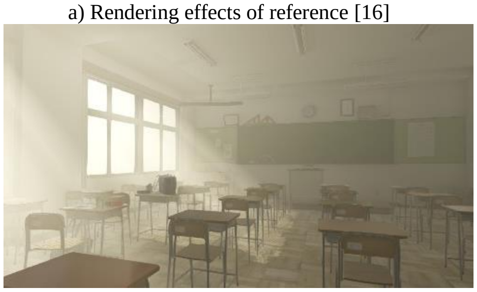
a) Rendering effects of reference

b) Rendering effect of this paper

Fig. 11. Comparison of light scattering effects in mountain scenes between this paper and reference [17].



a) Rendering effects of reference [16]



b) Rendering effect of this paper

Fig. 12. Comparison of indoor lighting scattering effects between this paper and reference [16].

The above experiments were all conducted in outdoor scenes, and our approach is equally applicable to indoor environments. Fig. 12 provides a comparative display of the light scattering effects in a classroom scene between our approach and the method proposed in reference [16].

Fig. 12(a) illustrates the rendering of a scene using the photon surface density estimation method from literature [16], which is suitable for handling cases with highly anisotropic phase functions. However, it fails to meet the requirements for real-time rendering. In contrast, Fig. 12(b) displays the rendering results obtained using the method proposed in this paper, achieving a frame rate as high as 76 FPS, meeting the standards for real-time performance. Moreover, the distribution of light and shadow in our method is similar to that in literature [16], presenting a trend of gradually diminishing brightness from the window to the interior of the room. Our method also achieves the effect of sunlight passing through glass windows, producing noticeable volumetric light beams. This greatly enhances the realism of the scene.

F. Performance Analysis

Table I lists the relevant data for each experimental scenario in this paper. The experimental data indicates that the method proposed in this paper can achieve real-time rendering frame rates in various experimental scenarios, with the sampling numbers not exceeding 256. Particularly, in smaller-scale scenes, higher rendering frame rates can be achieved. Compared to the methods in references [16], our approach has significant advantages in real-time rendering performance while maintaining consistent rendering quality.

TABLE I. EXPERIMENTAL DATA OF DIFFERENT EXPERIMENTAL SCENARIOS

Scenes	Sample Count	Atmospheric Density Ratio ρ	Scattering Coefficient	Resolution	Average Rendering Frame Rate (FPS)

V. CONCLUSION

In this paper, a real-time simulation method is proposed for light scattering effects in the atmosphere. By utilizing a physically-based atmospheric model that incorporates both Rayleigh and Mie scattering mechanisms, the total radiance equation is simplified and discretized, to construct a multiple scattering model. In addition, based on different light source characteristics, the method employs accurate ray marching path lengths, jittered sampling, and exclusion of shadowed region samples for lighting computations. This significantly reduces the required number of samples, resulting in a noteworthy enhancement in rendering efficiency, while maintaining stable rendering quality. Rendering is accomplished by utilizing an improved ray marching algorithm to achieve a more accurate simulation of scattering effects. In terms of simulating ambient light and sunlight, this paper optimized the gradient effects under different time and weather conditions. It blends the fog color with scene fragments during rendering, accurately presenting the various scattering properties of light in the atmosphere. In summary, the proposed method has demonstrated excellent performance in both real-time processing and realism, achieving a good balance between computational efficiency and visual effects. It provides valuable reference for further research and applications in the field of light scattering simulation, effectively enhancing the realism and three-dimensional sense of the scene while meeting real-time requirements.

Although our method can achieve real-time rendering in most scenarios, rendering efficiency can still be significantly impacted in cases involving large-scale scenes or high sampling counts. Future research could explore more efficient computational optimization methods to reduce the computational overhead. Meanwhile, the application of blur effects might result in some loss of detail. Efforts can be directed towards finding improved methods that allow for preserving the intricate details of simulation results to their maximum while still maintaining real-time rendering.

***Abstract*—In the rapidly developing field of the Internet of Things today, effective processing and analysis of perceptual data has become crucial. The perception data of the Internet of Things is usually large, diverse, and presents high-dimensional characteristics, which poses new challenges to data clustering algorithms. This study utilizes the K-center point algorithm to optimize the density peak fast search clustering algorithm, proposes a new clustering algorithm, and applies it to the research of semantic classification of perception data in the Internet of Things. Firstly, the K-center algorithm was used to optimize the clustering center optimization process of the density peak fast search clustering algorithm. Then, the optimized algorithm was applied to the automatic semantic classification model. Thus, a new automatic semantic annotation model for IoT aware data has been established. The research results showed that the classification accuracy of the proposed optimization algorithm was as high as 0.98, and the running stability of the automatic semantic annotation model optimized using this algorithm was as high as 0.99, with a running time as low as 1s. In summary, the automatic semantic annotation model built in this study can effectively improve the efficiency and accuracy of semantic classification, thereby providing more accurate and efficient data support for intelligent services.**

Keywords*—*Clustering algorithm; Internet of Things; perceived data; classification; peak density; semantic information

I. Introduction

With the rapid development of the Internet of Things (IoT) technology, more and more devices are connected to the Internet, generating a large amount of sensory data. These data are not only large and diverse in volume, but also exhibit high-dimensional characteristics, bringing unprecedented challenges to effective information processing and analysis [1-2]. Especially in intelligent service domains such as smart city, smart home, health monitoring, etc., how to accurately and efficiently extract valuable semantic information from massive perceptual data has become an urgent problem to be solved [3]. Clustering by Fast Search and Find of Density Peaks (CFSFDP) algorithm has gained wide attention in the field of data science due to its superior performance, especially in identifying the cluster centers, which shows significant advantages. However, CFSDP algorithms still face problems such as inconsistent sample density and sensitivity to noisy data when dealing with IoT sensory data [4]. In addition, the K-center algorithm has better robustness in data classification, but its performance is limited by the choice of centroids [5]. However, existing research mainly focuses on data acquisition and transmission optimization, with insufficient exploration of efficient data processing and accurate semantic classification, failing to give full play to the potential of IoT data in intelligent applications. This study intends to fill this research gap by proposing a Fusion Clustering Algorithm Based on K-Centroids and Fast Search of Density Peaks (FCA-KCFSDP) based on the optimization of K-centroid algorithm, which aims to improve the accuracy and efficiency of semantic information classification of IoT sensory data. This algorithm not only improves the stability and operational efficiency of the classification model by optimizing the clustering center searching process of the clustering algorithm, but also provides a strong technical support for achieving more accurate and personalized intelligent services. The contribution of this study is to clearly point out the shortcomings of the existing research and to achieve excellent performance in semantic information classification of IoT sensory data by proposing and validating a new clustering algorithm. The algorithm outperforms the existing clustering algorithms in terms of classification accuracy, operation stability, and operation time, which provides a new solution for the processing of IoT sensory data, as well as new ideas and methods for subsequent related research.

II. Related Work

CFSFDP is a density based clustering method aimed at addressing some of the limitations of traditional clustering algorithms when dealing with complex datasets. Many experts have conducted a series of studies using this clustering algorithm. In industrial applications, ensuring the reliability of rolling bearing rotating machinery is crucial. Wu J et al. proposed a new bearing fault diagnosis method that extracts bearing features through improved complete set empirical mode decomposition and uses CFSFDP for fault identification. This method was superior to traditional methods in fault diagnosis [6]. Chunhao Z et al. proposed an improved RNN-CFSFDP algorithm to address the limitations of the CFSFDP algorithm. This new algorithm redefined the sample density metric by introducing inverse nearest neighbors, enhancing the robustness of the allocation process, effectively reducing the domino effect, and avoiding incorrect selection of density peaks as clustering centers. The clustering performance of RNN-CFSFDP on manifold and non-uniform density datasets was superior to or equivalent to traditional methods [7]. To ensure vehicle driving safety, Wang H et al. studied vehicle stability identification and coordinated control. Firstly, a vehicle dynamics model was established using the vehicle simulation software Carsim, and an attribute dataset representing the lateral stability of the vehicle was obtained. Subsequently, the CFSFDP algorithm was applied to classify lateral stability. The final simulation results validated the advantages of the proposed method and coordinated control strategy [8]. Ren W et al. proposed an improved algorithm to address the limitations of the original CFSFDP algorithm in anomaly detection. This algorithm effectively reduced storage and computing costs by using a small number of key data points and reducing redundant data, while maintaining the arbitrary shape clustering characteristics of CFSFDP. Compared with traditional clustering algorithms, the improved CFSFDP algorithm performed better in generating anomaly detection files in terms of speed and accuracy, achieving a balance between detection accuracy and real-time performance [9].

The Semantic Information Classification (SIC) refers to the process of classifying text or data based on the semantic information it contains. Currently, many experts have used various algorithms to build various SIC models. Borges J B et al. proposed an IoT time series classification strategy and named it TSCLAS. TSCLAS is a time series classification strategy for IoT data, which mainly distinguishes different categories by transforming the original data into the ordinal pattern domain. At the same time, this strategy also enhanced the dynamic class separability of time series by selecting the optimal parameters. TSCLAS performed well in processing large-scale and incomplete IoT data, and had advantages in classification accuracy and computational time compared to other classification algorithms [10]. Wang Z et al. proposed a novel network structure for multi label image classification, which is a semantic supplementary network with prior information. This network first generated prior information through prior information networks with different convolutional layers, and then used semantic supplementation modules to generate semantic information of potential labels highly related to the current information based on the prior information. The proposed architecture achieved better classification performance in predicting certain semantic related labels [11]. Chen L et al. proposed a method for inferring regional level metadata from building automation system data to address the issue of inconsistent and incomplete metadata in existing building automation systems. Even in the absence of intuitive labels, the proposed information classification method could accurately classify and associate regional level building automation system points. The average accuracy of its classification and association stages was 90% and 85%, respectively [12]. Liu Z et al. proposed a global semantic memory network for aspect level emotion classification tasks. Traditional attention neural networks usually only consider the interaction between aspects in a single sentence and its context when solving this task, ignoring the rich semantic information available in other sentences. This network innovatively treated contexts with similar meanings as global semantic information and incorporated them as domain knowledge into the model to generate domain specific labels, proving its effectiveness [13].

In summary, many current studies have covered the application of CFSFDP and its variants in multiple fields. These studies indicate that the CFSFDP algorithm and its improved versions have advantages in processing high-dimensional, complex, and non-uniform density datasets, effectively identifying key information, and achieving efficient SIC in multiple application fields. However, these methods still have certain limitations in the processing of the IoT sensing data (IoT-SD), especially in terms of accuracy and efficiency of SIC. To further improve the classification performance of the current model for IoT-SD, this study aims to propose a new clustering method for optimizing the SIC of IoT-SD by combining the K-center point (K-CP) algorithm and the CFSDP algorithm.

III. SIC of IoT-SD Based on Improved Clustering Algorithm

To efficiently process these IoT-SDs, this study first fused K-CP and CFSFDP, designed a new clustering algorithm and named it Fusion Clustering Algorithm Based on K-Centroids and Fast Search of Density Peaks (FCA-KCFSDP). On this basis, an Automatic Semantic Annotation (ASA) model for IoT-SD was further designed, aiming to achieve automatic annotation of semantic information and improve the efficiency of information classification.

A. *Design of IoT-SD Clustering Algorithm Integrating CFSDP and K-CP*

In the CFSDP algorithm, local density and the minimum distance from data points to higher density points are two key basic concepts. Local density is usually measured by calculating the number of points around each point [14]. For each point, CFSDP calculates the distance from it to the closest point with higher density, which helps determine the cluster center. CFSDP typically uses a large number of samples to achieve efficient identification of cluster centers. In order to obtain more clustering centers, it is necessary to use the objective function in Eq. (1) for data selection [15].

$$Of = \sum_{i=1}^{n} p\left(obj_i, e_i\right) \tag{1}$$

In Eq. (1), Of represents the objective function. e_i represents an example of distance between multiple measurement objects. obj_i represents the measurement object. p represents the correlation between the measured object and the distance example. i represents the number of objects, and n represents the upper limit of their values. Assuming ρ_i represents local density, its calculation formulas are Eq. (2) and Eq. (3).

$$\rho_i = \sum_{j} \chi\left(d_{ij} - d_c\right) \tag{2}$$

In Eq. (2), d_{ij} and d_c represent the distance from object

obj_i to obj_j and the truncation distance, respectively. The density value $\chi(x)$ is represented by the difference between d_{ij} and d_c, and its specific value is Eq. (3).

$$\chi(x)=\begin{cases}1, x<0\\ 0, x\geq 0\end{cases} \tag{3}$$

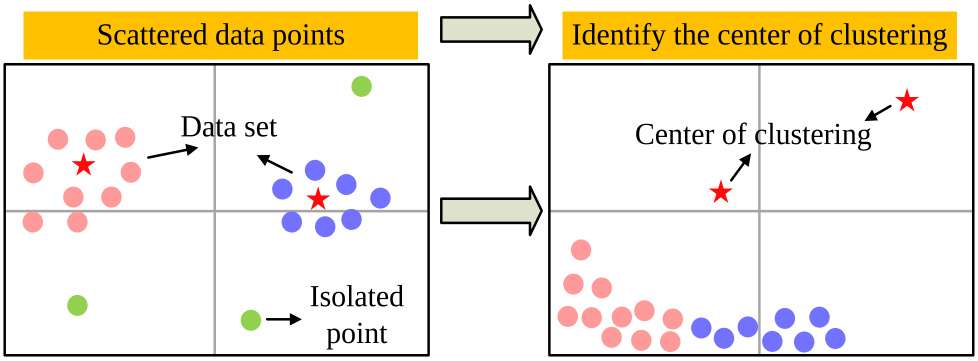
In Eq. (3), when the difference between d_{ij} and d_c is less than 0, i.e. $x<0$, the density value is $\chi(x)=1$. When the difference between d_{ij} and d_c is greater than or equal to 0, i.e. $x\geq 0$, the density value $\chi(x)=0$. Assuming that the minimum distance from a data point to a higher density point is δ_i, the calculation formulas are shown in Eq. (4) and Eq. (5).

$$\delta_i = \min \delta_i \quad \rho_j > \rho_i \tag{4}$$

In Eq. (4), when the local density ρ_j of obj_j is greater than the local density ρ_i of obj_i, the minimum distance δ_i can achieve a minimum value.

$$\delta_i = \max \delta_i \quad \rho_j \leq \rho_i \tag{5}$$

In Eq. (5), when ρ_j of obj_j is less than or equal to ρ_i of obj_i, the minimum distance δ_i can achieve a maximum value. Fig. 1 is the recognition decision diagram of the cluster center obtained by combining Eq. (1) to Eq. (5).



(a) Distribution of data before identification

(b) Distribution of data after identification

Fig. 1. Identification decision diagram of the clustering center.

Fig. 1(a) and (b) represent the distribution of surrounding data before and after cluster center recognition, respectively. Due to the high local density and minimum distance of the two pentagrams in Fig. 1(b) during the calculation process, these two points will be separately identified as outliers. And these two points happen to be the cluster centers of the two datasets in Fig. 1(a), so this method can be used to determine all the remaining cluster centers one by one. After determining all cluster centers, the remaining data will be automatically divided into nearby clusters based on the principle of nearest distance allocation. The identification formula for cluster centers is Eq. (6).

$$\gamma_i = \rho_i \times \delta_i \tag{6}$$

In Eq. (6), γ_i represents the product of local density and minimum distance. The larger the value, the more likely the data is to be the cluster center. Fig. 2 shows the running process of the CFSDP algorithm.

In Fig. 2, the execution of the CFSDP algorithm starts by calculating the local density of each data point. This step is usually achieved by quantifying the number of points within a certain radius around each point. Next, the distance from each point to the closest point with higher density and the local density value are calculated. Both local density and minimum distance serve as the axes of the decision graph to identify potential cluster centers. After determining the cluster center, the algorithm assigns the remaining points to the high-density points closest to them, forming independent clusters. Finally, to improve the accuracy of clustering, the algorithm will refine these preliminary clusters through a series of post-processing steps, and ultimately output the clustering results.

7
Output class labels
8
End

Fig. 2. Flowchart of running the CFSDP algorithm.

K-CP is similar to the K-means algorithm, but it differs in selecting cluster centers. In K-means, the cluster center is the mean of all points within the cluster, while in K-CP, the cluster center is the actual point that exists in the data, that is, the center point. Fig. 3 is the operational diagram of K-CP.

Output data
End

Fig. 3. Flow chart of the K-CP algorithm.

In Fig. 3, the calculation steps of K-CP are mainly divided into four parts: initializing the center point, data allocation, updating the center point, and multiple iteration algorithms. Assuming that all center point data (CPD) is denoted as m and non-CPD is denoted as o, the calculation formula for the exchange criterion function of CPD and non-CPD is Eq. (7).

$$E=\sum_{i=1}^{k}\sum_{p\in C_j} dist\left(p',o_i\right) \tag{7}$$

In Eq. (7), E represents the exchange criterion function. p' represents all objects. o_i represents an object in the C_j dataset. k represents the number of center points. To optimize the selection effect of the initial center point (ICP) of K-CP, this study adopts the dissimilarity measurement method to select the ICP, and its calculation is Eq. (8).

$$v_j=\sum_{i=1}^{n}\frac{d_{ij}}{\sum_{i=1}^{n}d_{ij}} \tag{8}$$

In Eq. (8), v_j represents the measure of dissimilarity of calculation object j. To sort the v_j values of each CPD and select the k objects with the top k minimum values as ICP.

Due to the fact that IoT-SD is usually high-dimensional, dynamically changing, and may contain noise and outliers, a single clustering algorithm is difficult to effectively handle such complex data. In order to improve the accuracy and robustness of IoT-SDSIC, this study combined CFSDP and K-CP to design FCA-KCFSDP, and its operating process is Fig. 4.

In Fig. 4, the calculation steps of the FCA-KCFSDP algorithm are mainly divided into three main steps: initialization clustering, initial cluster allocation, and cluster update. In order to optimize the FCA-KCFSDP, the study meticulously examined several key parameters, including the selection of the cluster radius, the density threshold, and the centroid selection criteria. The main rationale for selecting these parameter sets is based on the following considerations. When choosing the clustering radius, this study considered the distributional characteristics and density variations of the dataset. By comparing the effects of different radius values on the clustering results, it was ultimately found that the selected radius values could effectively differentiate between high-density regions and low-density regions, thus identifying the peak density points more accurately. In addition, the study also tried multiple radius values to evaluate their impact on classification accuracy and algorithm efficiency. The density thresholds were determined based on an in-depth analysis of the dataset features. By setting different density thresholds, it enables the final designed FCA-KCFSDP algorithm to control the tightness of clustering and thus optimize the clustering results. Different density thresholds were tried in this study, aiming to find a balance to ensure the quality of clustering while not over-dividing or merging real clusters. Finally, the choice of centroid directly affects the quality of clustering and the efficiency of the algorithm operation. The study develops a set of center point selection criteria based on the distribution characteristics and density information of the data. It is verified through pre-experiments that this set of criteria can effectively identify suitable clustering centers and improve the accuracy of clustering. In the initialization clustering stage, it is first necessary to calculate the local density and relative distance. Next, it is necessary to obtain the identification decision map of the clustering center based on the local density value, and calculate the initial clustering center based on the decision map. Then to change the center point of the cluster and calculate the distance from the object to the center point, obtaining the calculation formula for initial cluster allocation as shown in Eq. (9).

$$dist\left(a_i,a_j\right)=\sqrt{\sum_{t=1}^{n}\left(a_{it}-a_{jt}\right)^2} \tag{9}$$

In Eq. (9), a_i and a_j both represent objects. $a_{it}-a_{jt}$ represent the distance between two objects at time t. Introduce the variance of data objects as the weight factor for cluster center updates in cluster updates, and its expression is Eq. (10).

Fig. 4. Flowchart of running the FCA-KCFSDP algorithm.

$$\sigma_i = \sqrt{\frac{1}{n-1}\sum_{t=1}^{n} dist\left(t_i - a_j^2\right)} \qquad (10)$$

In Eq. (10), σ_i represents variance. t_i represents the closest data object. Based on Eq. (10), Eq. (11) is introduced to measure the total distance from all nearest data objects to object a_j.

$$D_i = \sum_{j=1}^{n}\left(dist_i - a_j\right) \qquad (11)$$

In Eq. (11), D_i represents the total distance. According to Eq. (11), it is possible to update the cluster and achieve dynamic classification of data, ultimately completing the SIC of IoT data.

B. Construction of ASA Model for IoT-SD

To improve the classification efficiency of IoT-SD and further achieve automatic classification of IoT-SD, this study combined the FCA-KCFSDP clustering algorithm to build an ASA model for IoT-SD. The current ASA research mainly focuses on two methods, namely pattern based and machine learning based semantic annotation methods. For data documents with consistent formats and preprocessed data, pattern based semantic annotation methods are more effective [16-17]. This method relies on identifying patterns and implementing specific rules based on data characteristics to perform semantic annotation. On the other hand, machine learning based methods are more suitable for processing text or other unstructured data types. This type of method typically combines natural language processing technology and various machine learning algorithms for data analysis and feature extraction to reveal hidden information and knowledge in text or data. Fig. 5 shows a common ASA model structure.

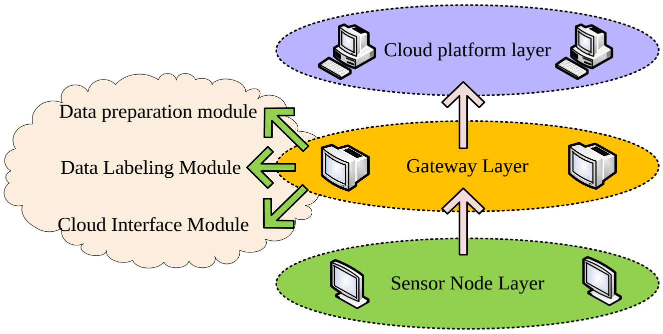

Fig. 5. Structure diagram of the traditional ASA model.

In Fig. 5, the entire ASA model consists of a cloud platform layer, a gateway layer, and a sensor node layer. The key architecture for implementing ASA is the gateway layer. In the gateway layer, it mainly includes three modules: data preparation module (DPM), data labeling module (DLM), and cloud interface module (CIM). DPM is mainly responsible for filtering and removing excess data, while converting the remaining data into XML format. This process analyzes and processes the initial data emitted by sensor nodes to minimize the computational resources required for the annotation process. Subsequently, DLM receives XML formatted data from DPM and annotates it, utilizing the concept of mapping to the application domain ontology to label the data. CIM is responsible for connecting cloud services and IoT data gateways, and implementing three main tasks. These include ensuring functional independence between the physical layer and the cloud service layer, transferring annotated IoT data to the cloud in RDF file format, processing sensor discovery content from upper layer applications, and querying requests for real-time data. The FCA-KCFSDP clustering algorithm was introduced as the core semantic classification component in the original ASA model, and the optimized structure of the IoT-SD oriented ASA model is Fig. 6.

Fig. 6 shows the ASA model with the addition of FCA-KCFSDP semantic classification component. The optimized ASA model consists of four parts, namely data pre-processing, semantic classification optimization (SCO), semantic annotation module (SAM), and CIM. Among them, the data pre-processing module aims to maintain the original functions of data aggregation, data filtering, and structured data representation. Structured data representation ensures that data is transformed in a way that is easy to process by the FCA-KCFSDP algorithm. The SCO module aims to replace the original semantic classification module with the FCA-KCFSDP clustering method. This module is responsible for assigning data to the correct semantic categories based on its characteristics and patterns. SAM will continue to receive the output of the semantic classification module and use domain ontology mapping and referencing concepts for semantic annotation of data. CIM refers to the transmission of semantically annotated data in RDF format to the cloud platform and processing of requests from the cloud platform and high-level applications. The optimized ASA model introduces the FCA-KCFSDP clustering method as the core of semantic classification, and all semantic classification work is carried out through this newly integrated algorithm. Compared to traditional ASA models, ASA models that use FCA-KCFSDP clustering method as the semantic classification core have better classification performance and adaptability. It not only enables reasonable clustering and annotation of various types of information, further reducing the need for subsequent data processing and storage, but also reduces computational costs without sacrificing performance.

IV. Results

To test the effectiveness of the research method, the results analysis section first tested the performance of the FCA-KCFSDP clustering algorithm and proved that the algorithm performed better than other comparative algorithms in error performance and SIC. Subsequently, this study applied the FCA-KCFSDP clustering algorithm to the ASA model and tested the model's performance in actual IoT-SD classification.

A. *Performance Testing of FCA-KCFSDP Clustering Algorithm*

To evaluate the performance of the FCA-KCFSDP clustering algorithm in the IoT-SD semantic classification problem, this study constructed a comprehensive dataset containing multidimensional temporal data as the experimental dataset. The data set consists of readings from different sensors, including temperature, humidity, light intensity, and motion sensor data. In addition, the data was collected from three different indoor environments, covering a duration of four weeks to ensure inclusion of various environmental changes and possible anomalies. Table I shows the specific dataset data.

Table I provides the dataset information for this study. To ensure that experimental errors caused by equipment changes can be avoided in multiple repeated experiments, this study conducted experiments in the same simulation environment. The experimental operating system is Ubuntu 20.04 LTS, with an Intel Core i7-9700K CPU @ 3.60GHz and 32GB DDR4 RAM. The algorithm design was completed using Python 3.8 and TensorFlow 2.4.1. Firstly, the changes in Mean Square Error (MSE) and Mean Absolute Error (MAE) of FCA-KCFSDP, CFSDP, and K-Means Clustering algorithms in the training dataset were compared, as shown in Fig. 7.

TABLE I. DATASET INFORMATION TABLE

Data Indicators	**Specific description**
Data Source	Indoor environment sensor data (temperature, humidity, light, motion)
Sampling Period	1 min
Total Duration	4 weeks

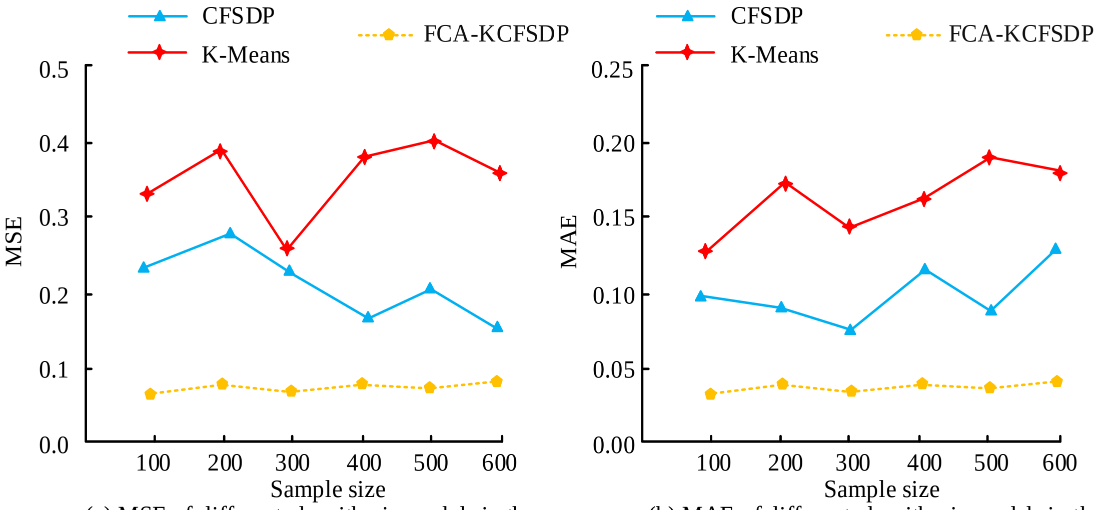
Fig. 6. Structural diagram of the ASA model for introducing FCA-KCFSDP.



(a) MSE of different algorithmic models in the training dataset

(b) MAE of different algorithmic models in the training dataset

Fig. 7. MSE and MAE for the different clustering algorithms.

Fig. 7(a) and Fig. 7(b) show the MSE and MAE values of the three clustering algorithms in the training dataset, respectively. In Fig. 7(a), as the number of training samples increases, the MSE value of the FCA-KCFSDP algorithm remains below 0.1, CFSDP is between 0.1 and 0.3, and K-Means is between 0.2 and 0.4. In Fig. 7(b), the increase in the number of training samples resulted in the MAE value of the FCA-KCFSDP algorithm always being below 0.05, CFSDP between 0.05 and 0.15, and K-Means between 0.10 and 0.20. In summary, the FCA-KCFSDP algorithm has better error performance.

Fig. 8(a) and 8(b) show the classification accuracy of the three algorithms in the training and validation sets, respectively. In Fig. 8(a), the FCA-KCFSDP, CFSDP, and K-Means algorithms have the highest classification accuracy in the training set of 0.96, 0.89, and 0.84, respectively. The highest classification accuracy of the three algorithms in Fig. 8(b) in the validation set is 0.98, 0.91, and 0.86, respectively. Therefore, the FCA-KCFSDP algorithm has higher classification accuracy in both training and validation processes, indicating that the algorithm can better perform SIC on experimental data.

The temperature, humidity, lighting, and motion data of indoor environmental sensors are classified separately, and the loss curves of three clustering algorithms on the four classification datasets are obtained. Fig. 9(a) to Fig. 9(d) indicate that compared to CFSDP and K-Means, the FCA-KCFSDP algorithm always obtains a more stable loss curve. The FCA-KCFSDP algorithm can achieve stable classification on four datasets: illumination, temperature, motion, and humidity by iterating 15, 22, 16, and 20 times respectively.

B. *Test of the Classification Performance of ASA Models for IoT-SD*

After testing the performance of the FCA-KCFSDP algorithm, this study applied it to the ASA model to further verify the classification performance of the IoT SDASA model optimized by the algorithm. Firstly, the operational stability and time variation of ASA models built by various clustering algorithms were compared, as shown in Fig. 10.

Fig. 10(a) to Fig. 10(c) shows the operational stability and time variation of three models under multiple actual tests. The above figure shows that the semantic annotation model combined with K-Means, CFSDP, and FCA-KCFSDP algorithms has the highest running stability of 0.79, 0.90, and 0.99, respectively, and the shortest running time of 19 seconds, 8 seconds, and 1 second, respectively. Therefore, applying the FCA-KCFSDP algorithm to the IoT-SDASA model can enable the model to have higher operational stability and shorter data classification time.

Fig. 11(a) and Fig. 11(b) show the satisfaction levels of IoT company users and experts with three different classification models, respectively. The satisfaction levels of users with the annotation models under K-Means, CFSDP, and FCA-KCFSDP algorithms are 0.76, 0.83, and 0.96, respectively. The satisfaction rates of experts with the models under K-Means, CFSDP, and FCA-KCFSDP algorithms are 0.72, 0.86, and 0.95, respectively.

(b) Expert satisfaction with classification models

Fig. 11. Satisfaction of users and experts with the classification model.

The classification effects of four different clustering algorithms in practical applications are given in Table II. One week's IoT sensing data was collected from an enterprise, which was divided into noisy data and non-noisy data, and 1,000 of each was taken. In Table II, the classification accuracy and classification time of K-Means algorithm are 84.25% and 1.87s for noisy data, and 86.32% and 1.59s for non-noisy data, respectively. The classification accuracy and classification time of CFSDPs algorithm are 88.30% and 1.38s for noisy data, and 88.30% and 1.38s for non-noisy data, respectively. The classification accuracy and time were 89.94% and 1.26s for noisy data. k-means++ algorithm was 91.05% and 1.12s for noisy data, and 92.17% and 1.05s for non-noisy data. fca-KCFSDP algorithm was 98.49% and 1.59s for noisy data. Classification time is 98.49% and 0.25s for noisy data, and 98.85% and 0.21s for non-noisy data. Taken together, all the clustering algorithms are better at dealing with noisy data than non-noisy data, and the FCA-KCFSDP algorithm, compared to the other three comparative algorithms, has higher classification accuracy and classification efficiency.

TABLE II. ACTUAL CLASSIFICATION EFFECT OF DIFFERENT ALGORITHMS

Algorithmic models	Data Type	Classification accuracy	Classification execution time
K-Means	Noise data	84.25%	1.87s
	Non-noise data	86.32%	1.59s
CFSDP	Noise data	88.30%	1.38s
	Non-noise data	89.94%	1.26s
K-means++	Noise data	91.05%	1.12s
	Non-noise data	92.17%	1.05s
FCA-KCFSDP	Noise data	98.49%	0.25s
	Non-noise data	98.85%	0.21s

V. CONCLUSION

In response to the shortcomings of low classification accuracy and poor classification performance of the current IoT SDSIC tool, this study combined the K-CP and CFSDP algorithms to design an optimized FCA-KCFSDP, and used it to build an ASA model for IoT-SD. The research results indicate that compared to K-means and CFSDP algorithms, FCA-KCFSDP clustering algorithm had better error performance, with MAE and MSE below 0.05 and 0.1, respectively. In addition, the classification accuracy of FCA-KCFSDP, CFSDP, and K-means algorithms in the entire dataset could reach up to 0.98, 0.91, and 0.86, respectively. The sensor data in the dataset was subdivided into four types of data: motion, humidity, temperature, and lighting. It was found that the FCA-KCFSDP algorithm can reach a stable state by iterating 15, 22, 16, and 20 times respectively. Therefore, the performance of FCA-KCFSDP algorithm was superior to the other two comparative algorithms. Finally, this study also compared the stability and running time of classification models under K-means, CFSDP, and FCA-KCFSDP algorithms, and found that their highest running stability reached 0.79, 0.90, and 0.99, respectively, and their shortest running time was 19 seconds, 8 seconds, and 1 second. The FCA-KCFSDP classification model could also achieve higher classification satisfaction. In summary, the clustering algorithm and classification model designed in this study can achieve good semantic classification results. Subsequent research can further expand the types of semantic information in the dataset, thereby proving that the model has better generalization properties. Future research work includes the following points. Firstly, explore the possibility of integrating density peak based fast search clustering algorithms with deep learning models to improve the accuracy and efficiency of the model when dealing with complex datasets. Secondly, the research will be extended to more application areas, such as intelligent transportation systems, environmental monitoring, etc., to verify the universality and applicability of the algorithm. In addition, focus on security and privacy protection during data processing, and study how to ensure algorithm performance while ensuring data security and user privacy are not compromised.

Abstract—**Cloud computing provides pay-per-use IT services through the Internet. Although cloud computing resources can help scientific workflow applications, several algorithms face the problem of meeting the user's deadline while minimising the cost of workflow execution. In the cloud, selecting the appropriate type and the exact number of VMs is a major challenge for scheduling algorithms, as tasks in workflow applications are distributed very differently. Depending on workflow requirements, algorithms need to decide when to provision or de-provision VMs. Therefore, this paper presents an algorithm for effectively selecting and allocating resources. Based on the workflow structure, it decides the type and number of VMs to use and when to lease and release them. For some structures, our proposed algorithm uses the initial rented VMs to schedule all tasks of the same workflow to minimise data transfer costs. We evaluate the performance of our algorithm by simulating it with synthetic workflows derived from real scientific workflows with different structures. Our algorithm is compared with Dyna and CGA approaches in terms of meeting deadlines and execution costs. The experimental results show that the proposed algorithm met all the deadline factors of each workflow, while the CGA and Dyna algorithms met 25% and 50%, respectively, of all the deadline factors of all workflows. The results also show that the proposed algorithm provides more cost-efficient schedules than CGA and Dyna.**

Keywords*—*Workflow scheduling; workflow structure; cloud computing; resource provisioning; deadline constrained; infrastructure as a service

I. Introduction

Cloud computing has become a significant platform for executing workflows as it allows the rental of resources on demand. It uses a pay-as-you-go billing model to provide IT resources over the internet [1]. This is done by renting virtual machines (VMs) with predefined CPU, memory, storage and network bandwidth capacities. To meet a wide range of application needs, customers can access various computing resources (i.e. VM sets) at different prices. Clouds offer infinite computing resources with different configurations that can be rented and used as needed. This architecture requires resource provisioning heuristics that run concurrently with a scheduling algorithm, which determines the amount and type of VMs to request from the cloud and the optimal time to rent and provision them.

Cloud computing today enables the execution of scientific applications consisting of hundreds or thousands of interdependent tasks [2]. Montage [3], CyberShake [4] and LIGO [5] are scientific workflow applications used in astronomy, earthquake science, and gravitational physics, respectively. A task does not begin its execution until all its predecessor tasks have been completed. Most of these scientific applications are built as workflows, which are groups of computational tasks linked by control and data dependencies. Each workflow phase consists of a different number of tasks, each requiring a different amount of computing resources. Depending on the application, a workflow can be extremely CPU-intensive and/or data-intensive. The complexity of task execution can vary from sequential execution to highly parallel execution with many inputs from different tasks.

The objective of the workflow scheduling problem in the cloud is to map tasks to resources to maintain task precedence while achieving certain performance metrics [6]. In the cloud, faster and more powerful computing resources are often more expensive than slower ones. As a result, using powerful computing resources can increase execution costs by shortening workflow execution time. Consequently, the trade-off between time and cost is a major challenge for cloud-based workflow scheduling [7]. Two typical approaches are used to solve this: reducing the total execution time under a budget constraint [8] and reducing the financial cost under a time constraint [9]. This study presents an approach to the problem of time-constrained workflow scheduling. The objective is to develop a workflow schedule for a given workflow that reduces the monetary cost of running the workflow in the cloud within a given time limit.

Creating an optimal schedule in a heterogeneous cloud environment is NP-hard [10]. On the other hand, workflow scheduling aims to reduce the overall time. Consequently, no algorithm can achieve an ideal solution in polynomial time, while certain algorithms can provide approximate results in polynomial time. Therefore, heuristics are required to find near-optimal solutions effectively.

In a cloud computing environment, it is challenging to select the type and amount of resources to use for the cost-effective execution of scientific workflows [6]. A shorter execution time can be achieved using many resources, but this could come at a significant financial cost. In recent years, a significant amount of research has been conducted on algorithms for scheduling scientific workflows, which are essential for maximising the benefits of cloud computing. However, these algorithms must focus not only on assigning tasks to resources but also on determining the amount and type of resources to be used (i.e., provisioning resources) during the execution of the workflow [11]. Moreover, it is necessary to determine when these resources should be provisioned and when they should be de-provisioned during the workflow execution.

In this study, we present a Deadline and Structure-Aware Workflow Scheduler (DSAWS), which is a heuristic. The algorithm is a static assignment of tasks to VMs with an elastic VM pool that provisions and de-provisions VMs for scheduling tasks as the workflow executes. The algorithm analyses the workflow structure to determine the type and amount of VMs to deploy and when to provision and de-provision them. The algorithm's first phase (the planning phase) selects the number and type of VMs to be used and the allocation of tasks to these resources. In the second phase, the algorithm provisions the VMs selected in the planning phase at the specified times. It also releases these VMs based on the times set in the first phase, considering the delay in provisioning/de-provisioning a VM in the cloud. Its main objective is to use these resources effectively to keep costs down without compromising deadlines.

We evaluated our algorithm using well-known workflows such as Montage, CyberShake, Inspiral, and Epigenomics, as this makes our results comparable to future studies. Finally, the experimental results of the DSAWS algorithm are compared with different scheduling algorithms such as Dyna[12] and CGA[16].

This approach reduces the overall execution cost of a workflow while meeting a user-defined deadline. Experimental results show that DSAWS outperforms other state-of-the-art algorithms in terms of meeting workflow deadlines while reducing execution costs. The experiments have shown that DSAWS delivers more cost-efficient schedules for various workflow applications than Dyna and CGA.

The remainder of the work is arranged as follows: Section II provides background information and reviews related work on workflow scheduling. The details of the design and implementation of the DSAWS algorithm are described in Section III. The experiment results are shown and discussed in section IV. Section V concludes the paper and future work.

II. Background Knowledge and Related Works

In this section, the presentation of scientific workflows is presented first. Then, related work on workflow scheduling with a problem statement on the clouds.

A. Background Knowledge

A workflow can be represented as a directed acyclic graph (DAG) consisting of a collection of atomic tasks. As shown in Fig. 1, the vertices of the workflow are a set of tasks $\{t_1, t_2, ..., t_n\}$, while the workflow edges represent data dependencies between these tasks. For example, during the execution of the workflow, the successor task t_4 waits for its predecessor task t_1 to complete its processing and produce its output data. When t_1 finishes, some of its data outputs become input dependencies for t_4. When t_4 is scheduled, its data input dependencies are sent to its target host to enable the successful execution of t_4.

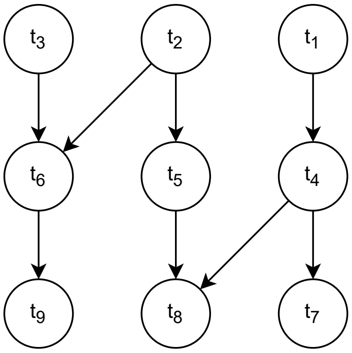

Fig. 1. A sample workflow.

B. Related Works

Many scheduling algorithms have focused on reducing the execution time of workflow applications in cloud computing. Heuristics and meta-heuristics-based approaches have been studied for the workflow scheduling problem.

Genetic algorithms (GA) [13] and Particle Swarm Optimisation (PSO) [14] are well-known meta-heuristic techniques. Moreover, meta-heuristic techniques such as GA and PSO can be found in the literature for workflow scheduling in the cloud. Verma et al. [15] presented a genetic algorithm that schedules cloud-based workflows depending on their importance to reduce the execution cost while meeting the workflow deadline. However, this algorithm does not consider the virtual machines' start-up time in the cloud. The paper [16] presents a genetic algorithm for deadline-constrained scheduling of workflows using the co-evolution technique to modify crossover and mutation probabilities to accelerate convergence and prevent prematurity. These approaches have the potential to be implemented in a cloud environment, although the waiting time might require the use of a computationally intensive meta-heuristic optimisation technique. The pre-processing duration may increase as the workflow size increases, leading to significant queuing delays.

Several heuristic algorithms [17], [18], [19], [20], [21] in the cloud computing environment are presented for workflow scheduling. Saeid et al. [20] presented a deadline-constrained approach for scheduling workflows that allocates an entire critical path to a single VM instance to reduce data transfer time between successive jobs. This technique does not consider allocating jobs from a single path to many VM instances in search of better scheduling options. This technique also does not consider the time it takes a provisioned VM instance to send all output data to the local storage of the VMs running the child tasks before it is de-provisioned. This is not practical during the period of process execution.

Xiumin et al. [22] have proposed a technique for extending HEFT [23]. It uses a two-step approach to reduce workflow makespan and execution costs simultaneously. However, it does not consider the startup time of a VM instance or the actual data transfer time between successive jobs. This algorithm selects the final scheduling solution from the K best solutions. However, the optimal determination of the value of K is not addressed. In the meantime, comparing the K scheduling solutions to choose the best one results in the scheduling algorithm's inefficiency.

The Coevolutionary Genetic Algorithm (CGA) [16] was proposed based on the biological evolutionary method (genetic algorithm), where the adaptive penalty function for strict deadlines was introduced. It assigns partial deadlines to each task and executes them on currently rented or existing VMs to reduce the total cost. CGA was chosen for comparison in our evaluation because of its static approach, which has the potential to generate optimal solutions. Nevertheless, our main interest is to compare DSAWS with CGA when both algorithms can meet deadlines. Moreover, by considering these algorithms, we can evaluate the adaptability of our results and show how DSAWS can meet deadlines while other algorithms fail to meet deadlines.

Dyna [12] is a scheduling technique developed with autoscaling capabilities for the cloud to dynamically provision and de-provision VMs depending on the current state of tasks. It was presented to develop a scheduling system that reduces the expected monetary cost under user-defined probabilistic scheduling constraints. It selects VM types for each workflow task based on an A-star search to reduce costs. It is designed to schedule many workflows simultaneously but can also be modified to schedule only one. Dyna was chosen for comparison in our evaluation because the algorithm is periodically improved by adjusting the number of VMs requested in each category to ensure timely completion of tasks at a lower cost. The aim is to show how the static component of DSAWS enables the creation of schedules that outperform the Dyna algorithm in terms of meeting workflow deadlines while reducing execution costs.

ARPS [24] is an algorithm for adaptive resource provisioning and scheduling for scientific workflows in Infrastructure as a Service (IaaS) clouds. It was designed to address cloud-specific issues such as unlimited on-demand access, heterogeneity, and pay-per-use (i.e., per-minute billing). Consequently, their strategy was also designed to consider a user's deadline and reduce the cost of the environment by using the resource provisioning and scheduling service. Finally, the experimental results show that they perform a workflow more effectively than other sophisticated algorithms to meet deadlines and reduce costs.

Mao et al. [25] proposed a workflow scheduling heuristic for the cloud environment that allows them to dynamically generate the lowest schedule while meeting the user's deadline. They investigated multiple VM types and cloud characteristics, such as alternative pricing models and acquisition delays. However, they did not consider data transfer time between linked jobs, which is one of the most important criteria and significantly impacts data-intensive workflows.

By analysing the workflow structure, [30] proposes a resource provisioning and scheduling technique that determines the required number and configuration of VMs. They claimed that their approach addresses data-intensive workflows to minimise data transfer. However, they did not consider the data transfer time between tasks during the execution of the two examples presented, which is one of the most important factors and significantly impacts workflow execution time. In addition, they neglected resource provisioning and deprovisioning delays in their experiments.

Researchers in [26] have presented a two-step method for provisioning cloud resources for workflows by minimising makespan and wastage of resources based on their structural characteristics. The proposed method considers the nature of the tasks, which may be computational, memory-, or storage-intensive. The performance of the presented algorithm is evaluated using five scientific workflows as benchmarks. Simulation results show that the proposed method outperforms two existing algorithms for each workflow.

Although there are several workflow scheduling techniques, there is a need for resource estimation for workflow execution because the above approaches have not analysed the workflow structure in depth. In this paper, we propose DSAWS, which is a complete full-ahead scheduling algorithm that considers the structure of the workflow. We discuss a method to deal with under- and over-provisioning issues.

III. The Proposed Scheduling Algorithm

Several objectives associated with task scheduling issues need to be addressed. The approach suggested in this paper focuses on running workflow applications in a cloud environment to lower overall execution costs while still meeting the user-set deadline. The proposed technique analyses the workflow structure, determines the number of tasks at each level, and provides a rank value for all workflow tasks. To determine the quantity and configuration of resources needed to complete the workflow execution by the user-set deadline, use this rank value.

Two approaches are discussed. First, in the planning phase, the exact number and configuration of VMs that need to be rented from cloud service providers are determined based on the deadline constraint and the ranking value of the tasks. It also uses the remaining time (leftover time) in the current billing period to avoid wasting resources. The plan to reuse cloud resources can eliminate the need for further provisioning and deployment costs.

The second approach concerns the execution phase (the second phase). It aims to provision or de-provision the resources of the selected services for tasks in the planning phase. These resources are maintained until they have completed all the previously assigned tasks. However, if some resources are not needed for the subsequent tasks, they are terminated immediately after the output data is transferred. This significantly reduces execution time and resource costs, which is crucial for workflow users. We will explain the steps of Algorithms 1 and 2 in the next paragraph using Table I, which contains the notations used in our algorithms.

Algorithm 1 calculates the rank value of each task, starting with the exit tasks (tasks without any child). First, the runtime of each exit task became its rank value for those tasks that have no child tasks (lines 2-6), and then the rank value is assigned to the parent tasks of the exit tasks (lines 7-15), which involves calling Algorithm 2 (line 11).

Second, Algorithm 2 assigns to each parent task the maximum rank value of the rank values of its child tasks (lines 2-8) with the maximum data size of the data sizes of its child tasks (lines 9-12). Algorithm 2 continues assigning the rank value

TABLE I. NOTATIONS FOR THE SYMBOLS USED IN THE ALGORITHMS

Notations	Meanings
$T(G)$	Set of tasks in workflow graph.
D	User-defined deadline of the workflow.
E	Set of edges between tasks in workflow.
t_{entry}	Task without any parent.
t_{exit}	Task without any child.
t_{EST}	Earliest Start Time of task t.
t_p	Predecessors (parents) of task t.
p_p	Predecessors of predecessor p.
t_{ch}	Successors (children) of task t.
$t_{runtime}$	Runtime of task t.
t_{rank}	Rank value of task t.
$readyList$	List of the ready tasks in workflow.
$rankList$	List of all tasks in descending order of their rank values.
s^{speed}	Performance capacity of service type s.
vm^{speed}	Performance capacity of virtual machine vm.
$VMsList$	List of selected VMs with scheduled tasks on them during the planning phase.
m	Number of VM types.
n	Number of currently leased VMs.
vm_{start}	Start time of virtual machine vm.
vm_{stop}	Stop time of virtual machine vm.
$vm_{idleTime}$	Idle time of virtual machine vm.
$vm_{billingPeriod}$	Billing period of virtual machine vm.
$t_{transferTime}$	Transfer time of all output data of task t to the VMs of its successors ch.

Algorithm 2 Task Ranking

```
1:  procedure TASKRANK($p$)
2:      $ch_{maxRank}$ := 0
3:      $ch_{maxData}$ := 0
4:      for each child $ch$ of $p$ do
5:          if $ch$ has rank value then
6:              if $ch_{rank} > ch_{maxRank}$ then
7:                  $ch_{maxRank}$ := $ch_{rank}$
8:              end if
9:              if $ch_{data} > ch_{maxData}$ then
10:                 $ch_{maxData}$ := $ch_{data}$
11:             end if
12:         end if
13:     end for
14:     $p_{rank}$:= $p_{runtime}$+$maxRank$+$maxData$
15:     if $p$ has parent then
16:         for each parent $p_p$ of $p$ do
17:             call TaskRank($p_p$)
18:         end for
19:     end if
20: end procedure
```

for each task recursively until it reaches the entry tasks that have no parent tasks (lines 15-19). Finally, after Algorithm 2 completes its steps, Algorithm 1 sorts all tasks in descending order according to their rank values to determine the order in which workflow tasks should be scheduled (line 16). In the next paragraphs, we will explain the steps of the Algorithms 3 and 4.

Algorithm 1 Workflow Ranking

```
1:  procedure ASSIGNRANKING($T(G)$)
2:      for all $t \in T(G)$ do
3:          if $t$ has no children then
4:              $t_{rank}$:= $t_{runtime}$
5:          end if
6:      end for
7:      for all $t \in T(G)$ do
8:          if $t$ has no children then
9:              for each parent $p$ of $t$ do
10:                 if $p$ has no rank value then
11:                     call TaskRank($p$)
12:                 end if
13:             end for
14:         end if
15:     end for
16:     Arrange all tasks in the list $rankList$ in decreasing
        order of rank values.
17: end procedure
```

The pseudocode of the entire DSAWS algorithm for workflow scheduling is shown in Algorithm 3. The proposed algorithm uses the rank value to support each task by selecting the appropriate VM to execute it within the deadline. In the first phase, the algorithm selects the appropriate type and the exact number of VMs needed to execute workflow tasks to meet the deadline set by the user. After the basic initialisation in lines 2-8 of Algorithm 3, it receives the workflow tasks arranged from Algorithm 1 while the deadline D is set by the user. Line 2 identifies the available instance types of VMs the service provider offers. In line 3, the rented set $rentedVMs$ is empty at the beginning of the execution of the algorithm. We have initialised a variable called $success$ that changes when a task finds its matching VM to meet the deadline. In line 6, $vm_{minTime}$ is the earliest available VM time in the currently leased VMs. In line 7, although all tasks are arranged in descending order of their rank values, Algorithm 3 selects ready tasks from the $rankList$ and adds them periodically to the $readyList$ in order. In line 8, $timeLine$ is the difference between the earliest available time of the VM or the earliest start time of a task and a deadline D. The while loop in line 9 is used to find a suitable VM for each task in the workflow. In line 12, the $timeLine$ is the difference resulting from subtracting $vm_{minTime}$ from the deadline because the task begins its execution by selecting a VM instance that has already been rented. First, the ready tasks check the available rented VMs to meet the deadline. If a task does not find a suitable VM to meet the deadline, it selects a new suitable VM to meet the deadline. At the beginning of the execution of the algorithm, there are no rented VMs in line 13. Therefore, the algorithm skips lines 13-20. In line 22, the $timeLine$ is the difference resulting from subtracting the earliest start time of a task (t_{EST}) from the deadline since the task begins its execution by selecting a new VM instance. Line 23 tries to select a new VM by comparing $timeLine$ with the task's rank value divided by the VM speed (lines 13 and 23). For cost-effective task scheduling, the task searches for a VM at the service provider, starting with the slowest VM until it reaches the appropriate VM that meets the deadline (lines 24-25). In line 26, the task is removed from the unscheduled $readylist$, while in line 28, the selected new VM is added to the set of rented VMs ($rentedVMs$). The algorithm updates the EST for all successors of a task (line 16 or 27) after finding a suitable resource in line 15 or 25. This update may change the readiness of the tasks based on the completion time of their predecessor tasks. When all tasks are assigned to VMs, the algorithm calls Algorithm 4 in line 33.

Algorithm 4 shows the pseudocode of the TimelineVMS algorithm for provisioning and de-provisioning resources. In the second phase, the algorithm first determines the time for provisioning the VMs and the time at which each VM is de-provisioned by taking into account the delays in provisioning and de-provisioning a VM in the cloud. Second, the algorithm determines the idle time between two scheduled, consecutive tasks on each VM. During the execution of the workflow, the algorithm dynamically adds and removes resources from its pool.

Algorithm 3 The DSAWS scheduling algorithm

```
procedure DSAWS(G($T$,$E$),$D$)
    $m$= available instance types of VMs ($S$)
    $rentedVMs = \varnothing$ the currently leased virtual machines
    $success$ = false.
    $vm_{booting}$ = the booting time of VM
    $vm_{minTime}$ = the earliest available time of $vm$ in $rentedVMs$.
    $readyList$ = receives repeatedly ready tasks from $rankList$.
    $timeLine$ = represents the difference of subtracting $vm_{minTime}$ or $t_{EST}$ from the deadline $D$.
    while (there exists unscheduled $t$ in $readyList$) do
        $t$ = find the earliest EST in $readyList$
        $vm_{minTime}$= find the earliest available time of $vm$ in $rentedVMs$.
        $timeLine$ := $D$ - $vm_{minTime}$
        for all $vm_j \in VM$ do where $j = 1, 2, \dots, n$
            if $timeLine >= \frac{t_{rank}}{vm_j^{speed}}$ then
                select $vm_j^{speed}$ to run $t$
                update EST for all successors of $t$
                remove $t$ from $readyList$
                $success$ := true
            end if
        end for
        if success==false then
            $timeLine$ := $D$ - $t_{EST}$
            for all $s_i \in S$ do where $i = 1, 2, \dots, m$
                if $timeLine >= (\frac{t_{rank}}{s_i^{speed}})$ then
                    select a new instance $vm_i^{speed}$ to run $t$
                    remove $t$ from $readyList$
                    update EST for all successors of $t$
                    add $vm_i^{speed}$ to $rentedVMs$
                end if
            end for
        end if
    end while
    call TimelineVMs(VMs)
end procedure
```

Algorithm 4 represents the second phase, where workflow tasks are scheduled on the selected resources ($VMsList$) during the planning phase. It receives from Algorithm 3 a schedule for all tasks about the types and number of their VMs ($VMsList$). After initialisation in lines 2-5, the booting and shutdown times of resources and the VM's billing period are set. In line 5 of the algorithm, $vm_{idleTime}$ is used to find the idle time between any two scheduled consecutive tasks on a VM to shut down this VM.

Algorithm 4 Provisioning resources

```
 1: procedure TimelineVMs($VMsList$)
 2:     $vm_{booting}$ = the booting time of VM
 3:     $vm_{shutdown}$= the de-provisioning time of VM
 4:     $vm_{billingPeriod}$ = the billing period for VM
 5:     $vm_{idleTime}$= the idle time between two consecutive tasks on the VM.
 6:     for all $vm \in VMsList$ do
 7:         for each task $t$ on $vm$ do
 8:             if $vm$ has not provisioned then
 9:                 $vm_{start}$=($t_{start} - vm_{booting}$)
10:                 if $vm_{start} < 0$ then
11:                     $vm_{start}$=0
12:                 end if
13:                 provision $vm$ on the time of $vm_{start}$
14:             end if
15:             $vm_{idleTime}$= $vm_{idleTime}$ - $vm_{shutdown}$
16:             if $vm_{idleTime} >= vm_{billingPeriod}$ then
17:                 transfer output data of $t$ to the VMs of its successors.
18:                 $vm_{stop}$= $t_{end}$+$t_{trasferTime}$
19:                 de-provision $vm$ on the time $vm_{stop}$
20:             end if
21:         end for
22:         transfer output data of $t$ to the VMs of its successors.
23:         $vm_{stop}$= $t_{end}$+$t_{trasferTime}$
24:         de-provision $vm$ on the time $vm_{stop}$
25:     end for
26: end procedure
```

To do this, the VM's billing period is taken into account to determine whether the idle time is greater than the billing period of a VM. For example, if workflow tasks are scheduled on VMs in the first phase, the algorithm determines when to start a VM and when to shut it down in the second phase by checking the schedule of the tasks on their VMs. This reduces the idle time of VMs and gaps in scheduling between workflow tasks. In lines 6 and 7, the algorithm identifies the tasks of each VM by reading the start and end times of each task on it. The algorithm then attempts to prepare tasks' resources before the tasks begin their execution (lines 9-12), as the provisioning process is still significant due to the overhead associated with leasing virtual machines (lines 8–14). The consequences of VM provisioning and de-provisioning delays are greatly mitigated and are much easier to manage.

First, the algorithm uses resource elasticity to meet the user's deadline but knows when to rent and release resources. If a new VM needs to be provisioned during the execution of the workflow, the algorithm can start VMs earlier before the task starts by taking into account the delay in provisioning a VM instance to speed up the execution of the workflow because provisioning a VM takes time. Secondly, it uses the cloud billing model to optimise resource utilisation while reducing the number of rented resources. It also tries to schedule tasks on currently rented VMs to reduce the need for further VM provisioning costs.

Furthermore, the algorithm checks the timeline of each VM to see if the idle time is greater than the instance's billing period (lines 16-20). It then sends the output data to the VMs performing the successor tasks (line 17) before de-provisioning that VM instance in line 19. Finally, it sends the output data to the VMs executing the successor tasks, if any (line 22), before de-provisioning that VM instance in line 24 because the VM has completed its tasks.

A. An Illustrative Example

To illustrate how the proposed algorithm works, we apply its steps to a sample workflow shown in Fig. 2. The workflow consists of nine tasks in the nodes of the graph: $t_1 - t_9$. The value within the node of each task indicates the estimated time of its execution (in seconds), while the number in parentheses represents the rank value. The estimated time for data transfer between VMs is also shown on the edges between nodes.

The following sections explain how to use the new algorithm to perform the workflow. Before the algorithm starts, the rank value for all tasks should be calculated using Algorithms 1 and 2. Then the tasks are sorted in descending order of their rank value. We assume that the cloud provider offers three types of VM computing services (vm^1, vm^2 and vm^4) to execute the workflow tasks. The billing period for computing services is set to 10 seconds, and the costs for vm^1, vm^2 and vm^4 are 2, 4 and 6 respectively. The speeds for vm^1, vm^2 and vm^4 are 1, 2 and 4, respectively. The VM instance provisioning and shutdown delays are set to 2 and 1 second, respectively, and the workflow deadline is set to 35, which is the maximum rank value (32) in the workflow, plus the provisioning (2) and de-provisioning delays (1).

For the example workflow in Fig. 2, we call the DSAWS scheduling algorithm, i.e., Algorithm 3. At the beginning of the workflow execution, $t_1 - t_3$ are the ready tasks that need to be scheduled and steps 13-20 of Algorithm 3 are not applied since no VMs have been provisioned yet. Therefore, steps 21-31 are executed, running the for loop in line 23 one or more times until each task finds its appropriate resource (s_1^1) to execute that meets the user's deadline. The value EST is calculated for the successor tasks of t_2 in step 25.

Steps 13-20 can be executed if some resources are available. A task checks the available rented resources (vm_1^1), starting with the slowest and then the fastest (in ascending order by speed). If a task (t_1) does not find a suitable resource that completes execution within the deadline, it decides to start a new instance of available services (s_2^1) considering the speed of the resource in step 24. Similarly, t_3 will select a new instance (s_3^1) that can complete execution within the deadline. Table II shows the scheduled tasks, the selected VMs, and the execution time (in seconds) of each task.

Step 1: First, the DSAWS algorithm assigned t_2, t_1, and t_3 to vm_1^1, vm_2^1, and vm_3^1, respectively. The algorithm started three VMs to meet the user's deadline, and the current simulation time was two due to the VM booting time.

Step 2: The algorithm assigned t_5 to the available instance vm_1^1, so no data transfer occurred. The same is occurred for steps 3 and 4: t_4 and t_6 were assigned to the instances of their predecessor tasks vm_2^1 and vm_3^1, respectively. Finally, the last three steps used the same available instances of their predecessor tasks without data transfer. After all, tasks have been scheduled. The next step is called Algorithm 4 in step 33 to provision and de-provision the resources of the services assigned to the tasks during the previous phase (the planning phase).

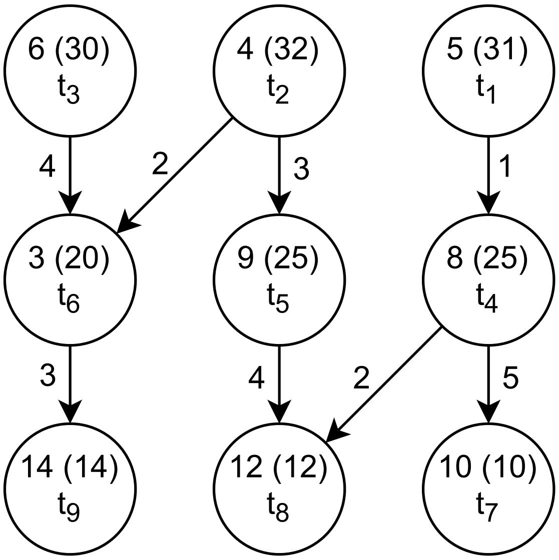

Fig. 2. A sample workflow.

Finally, Algorithm 4 receives from Algorithm 3 the schedule (e.g., Table II) indicating the time of execution of each workflow task on each resource of the service type. In lines 2-5, the algorithm sets several variables, e.g., the periods for starting up (e.g., 2) and shutting down (e.g., 1) of the resource. The variable in line 4 is the instance's billing period (e.g., 10). In line 5, this variable will check the idle time between any two consecutive tasks on each VM. The for loop in line 6 is executed for all VMs assigned during the planning phase ($vm_1^1 - vm_3^1$). Then, the for loop in line 7 is executed for all tasks on each VM (e.g., t_2, t_5 and t_8 on vm_1^1). Since no VM is provisioned at the beginning of the workflow execution, the delay in booting the VM cannot be avoided (lines 8-14).

However, the other tasks ($t_4 - t_9$) that start at a time greater than the booting delay can start executing and thus avoid the VM booting delay. The algorithm provisions VMs (vm_{start}) in advance of the tasks' start times (line 9), taking into account the VM provisioning delay ($vm_{billingPeriod}$). Finally, if a VM has subtracted the shutdown delay time from the VM idle time (line 16) and the difference is greater than or equal to the instance's billing period (line 16), the VM is terminated immediately after the output data is transferred to the VMs of its successors (lines 15-19).

Furthermore, if no more tasks are running on a VM, the VM is also terminated immediately after the output data has been transferred to the VMs of its successors (lines 22-24). The makespan for the workflow with the selected VMs ($vm_1^1 - vm_3^1$) is 30 seconds. Taking into account the data transfer time and the delay times for booting and shutting down the VM instances, the total cost of the sample workflow is 18.

TABLE II. THE SCHEDULING OF THE WORKFLOW TASKS FOR EACH STEP OF EXECUTING DSAWS ON THE SAMPLE WORKFLOW OF FIG. 2

Step	Task	Rank	Current Sim Time	timeLine	$\frac{t_{rank}}{vm_j^{speed}}$	VM selection	Start	End	VM cycle
1	t_2	32	2	32	32	vm_1^1	2	6	1
1	t_1	31	2	32	31	vm_2^1	2	7	1
1	t_3	30	2	32	30	vm_3^1	2	8	1
2	t_5	25	6	28	25	vm_1^1	6	15	2
3	t_4	25	7	27	25	vm_2^1	7	15	2
4	t_6	20	8	26	20	vm_3^1	8	13	2
5	t_9	14	13	21	14	vm_3^1	13	27	3
6	t_8	12	15	19	12	vm_1^1	15	29	3
6	t_7	10	15	19	10	vm_2^1	15	25	3

TABLE III. THE CHARACTERISTICS VALUES FOR EACH WORKFLOW APPLICATION

Workflow type	Number of levels	Number of tasks	Number of dependencies	Mean runtime (sec.)	Mean data size (MB)
Montage	9	1000	4485	11.37	3.21
CyberShake	5	1000	3988	22.75	102.29
LIGO	6	1000	3246	227.7	8.9
Epigenomics	8	997	3228	3866.4	388.59

IV. EVALUATION

Our experiment evaluated DSAWS with other competitive algorithms like CGA and Dyna for scheduling the selected scientific workflow applications. The experiment was conducted in the DISSECT-CF-WMS [27] simulator, which is an extension of the DISSECT-CF simulator. It is useful for running scientific workflows on cloud resources. DISSECT-CF-WMS focuses on the user-side behaviour of clouds, while DISSECT-CF focuses on the internal behaviour of IaaS systems. It also supports dynamic provisioning to meet the resource requirements of the workflow application while running on the infrastructure, taking into account the provisioning and de-provisioning delays of a cloud-based VM.

We used a library of realistic workflows introduced by Bharathi et al. [28] to evaluate our scheduling algorithm. We evaluate our algorithm by simulating it with synthetic workflows based on real scientific workflows with different structures. We selected four realistic workflows from different scientific applications, which are Montage from the field of astronomy, CyberShake from the field of earthquake science, Inspiral (LIGO) from the field of gravitational physics, and Epigenomics from the field of biology. Fig. 3 shows the structure of each workflow. All relevant characteristic values required for the above algorithms are listed in Table III for the analysis of experiments. We have used these values to obtain the rank values and assign the corresponding VM to each task. The performance of the four workflows in DSWAS is compared with Dyna and CGA approaches.

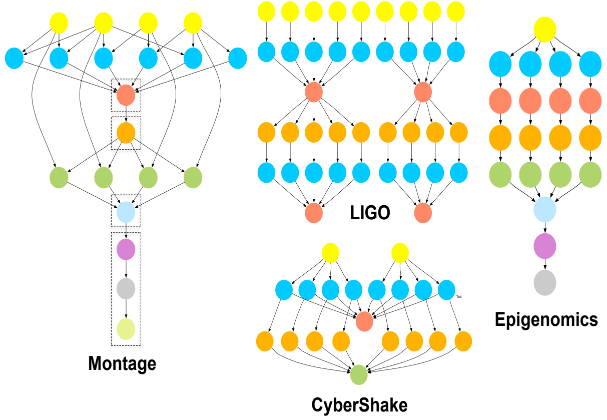

Fig. 3. The structure of the Montage, CyberShake, LIGO and Epigenomics workflows [28].

TABLE IV. TYPES OF VM BASED ON GOOGLE COMPUTE ENGINE OFFERING

Name	Memory (GB)	Google compute engine units	Price per minute($)
n1-standard-1	3.75	2.75	0.00105
n1-standard-2	7.5	5.5	0.0021
n1-standard-4	15	11	0.0042
n1-standard-8	30	22	0.0084
n1-standard-16	60	44	0.0168
n1-standard-32	120	88	0.0336
n1-standard-64	240	176	0.0672

We created a model of the cloud infrastructure of Google Cloud Engine[1] with different VM configurations selected from the predefined machine types of the cloud. An IaaS provider with a single data region and seven types of VMs was set up. Table IV shows the VM setup type based on Google Compute Engine offerings. For Google Cloud Engine, the core of Compute Engine CPU provides a minimum processing capacity of 2.75 GCEUs (2.75 ECUs), or about 2750 MIPS [29]. A billing slot of 60 seconds was modelled, as service providers such as Google Compute Engine and Microsoft Azure offered. Provisioning delay was set to 30 seconds [31] and de-provisioning delay to three seconds [25] for all types of VMs. The bandwidth between VMs was set to 1 Gbit.

To evaluate the ability of each approach to achieve a valid solution that meets the deadlines, we set the success rate metric, which is calculated as the proportion of the current execution times to the given deadlines. For the evaluation, we set three deadline factors based on the maximum rank value of each workflow. The maximum rank value represents the strict deadline factor (1), as shown in Table V. In addition, the moderate and relaxed deadlines are obtained by multiplying the maximum rank values by (1.5) and (2), respectively.

Fig. 4, 6, 8, and 10 show the results of the success ratios for each workflow with the three algorithms. On the other hand,

TABLE V. THE MAXIMUM RANK VALUES IN SECONDS FOR EACH SCIENTIFIC WORKFLOW

Workflow type	The maximum rank value (strict Deadline factor)
Montage	369 seconds
CyberShake	736 seconds
LIGO	625 seconds
Epigenomics	27232 seconds

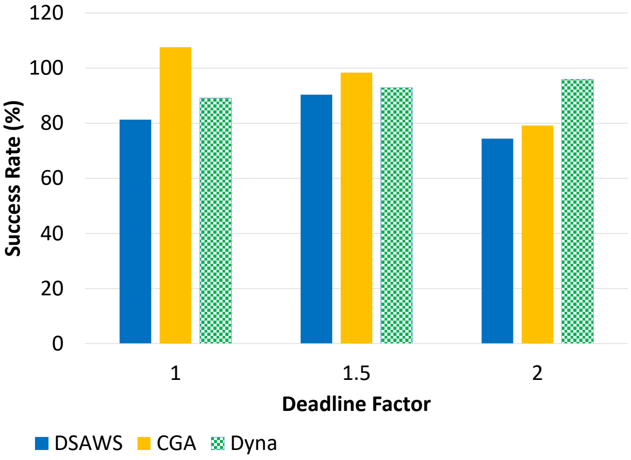

Fig. 4. The makespan of the three algorithms with the montage application.

Fig. 5, 7, 9, and 11 show the execution costs (in $) for each workflow with the same algorithms.

In the case of Montage workflow, all algorithms completed the execution of the workflow within the deadline, except CGA, with the strict deadline factor, as shown in Fig. 4. Dyna met all deadline factors, as shown in Fig. 4. The DSAWS approach met all deadlines with the lowest cost compared to the other algorithms, as seen in Fig. 5. The Montage workflow has many parallel tasks with a short execution time in the second level. This drastically increases the overall cost of the workflow as more resources are consumed by Dyna, as shown in Fig. 5. However, DSWAS overcomes this disadvantage by using the leftover time of resources to save costs. Furthermore, Montage has nine levels and six of these levels are controlled by the single-thread jobs with a total execution time of 332 seconds. Levels 3 and 4 have 142 seconds, which is more than two instance cycles, with the billing period being 60 seconds. Levels 6-9 have 190 seconds, which is equivalent to three instance cycles. Therefore, the DSAWS algorithm keeps only one VM during these periods to reduce the execution cost and meet the deadline.

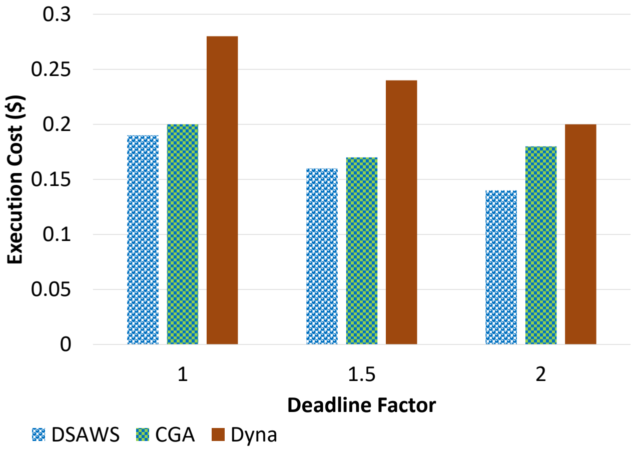

Fig. 5. The execution cost of the three algorithms with the montage application.

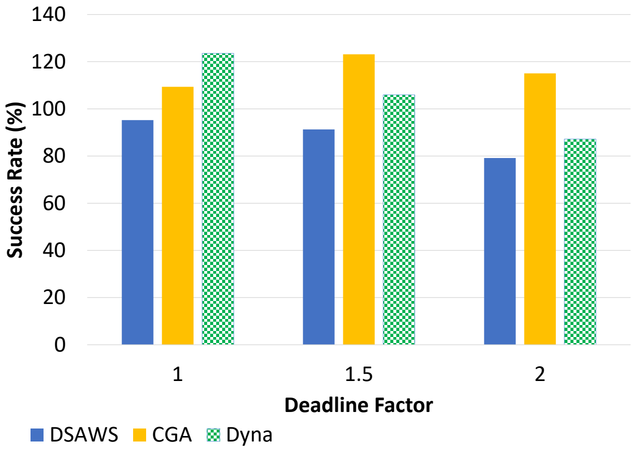

Fig. 6. The makespan of the three algorithms with the CyberShake application.

In the case of the CyberShake workflow, which has a data transfer bottleneck for most scheduling algorithms. This drawback is eliminated by the DSAWS described in this paper, which allocates resources to all tasks based on their rank value. It guarantees that all tasks are completed within the deadline and starts new instances only when needed. Therefore, DSAWS reduces data transfer by assigning tasks to the same set of resources. The CGA scheduler could not meet the deadline for all deadline factors successfully. While Dyna met the relaxed deadline factor, it failed to meet the other deadline factors. DSAWS, on the other hand, meet all deadlines with the lowest execution cost, as shown in Fig. 6 and Fig. 7, respectively. CyberShake has five levels, with most tasks at levels 2 and 3 totalling 994 tasks out of 1000. This results in high concurrency and a large amount of data transfers. CyberShake is a compute- and data-intensive workflow. In addition, level two has 497 tasks with 95.35% of the total execution time of the workflow tasks. As a result, the Dyna and CGA algorithms launched many instances of the computation service, and this has led to an increase in the makespan and execution cost of the workflow due to the increase in data transfers between resources.

In LIGO, DSAWS successfully met all deadline factors, while CGA failed to meet all deadline factors. Dyna met the relaxed deadline factor but failed to meet the other deadline factors, as shown in Fig. 8. CGA and Dyna perform badly because fewer resources are available for tasks with long execution times. LIGO is a data and CPU-intensive workflow, and this slowed down the execution of the workflow significantly. However, the proposed technique analyses the workflow structure, determines the number of tasks at each level and provides a rank value for all workflow tasks. The algorithm then assigns the appropriate type of resources to these tasks

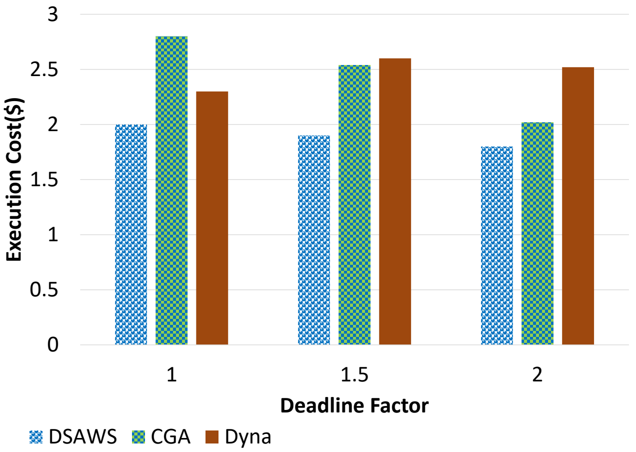

Fig. 7. The execution cost of the three algorithms with the CyberShake application.

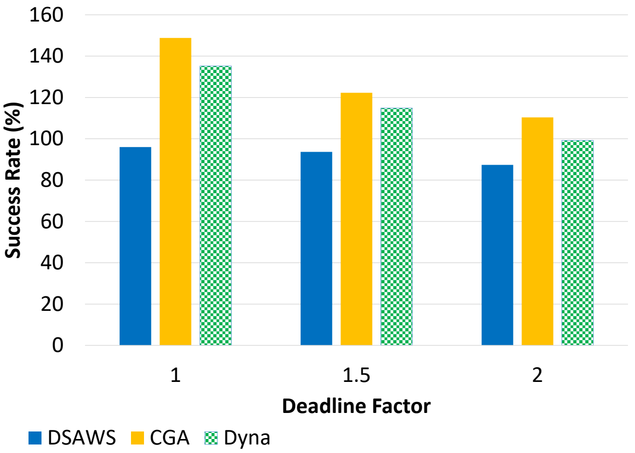

Fig. 8. The makespan of the three algorithms with the LIGO application.

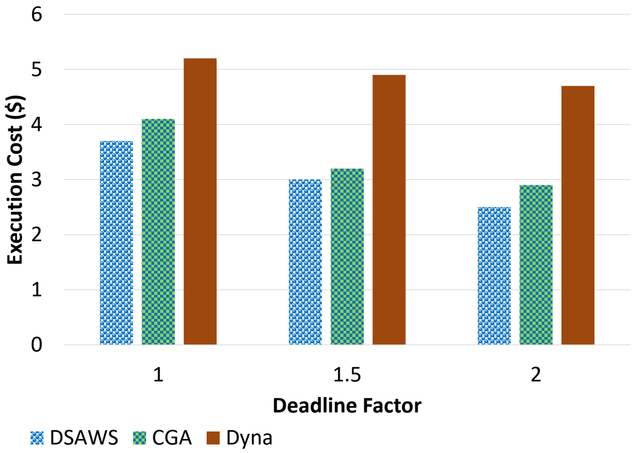

Fig. 9. The execution cost of the three algorithms with the LIGO application.

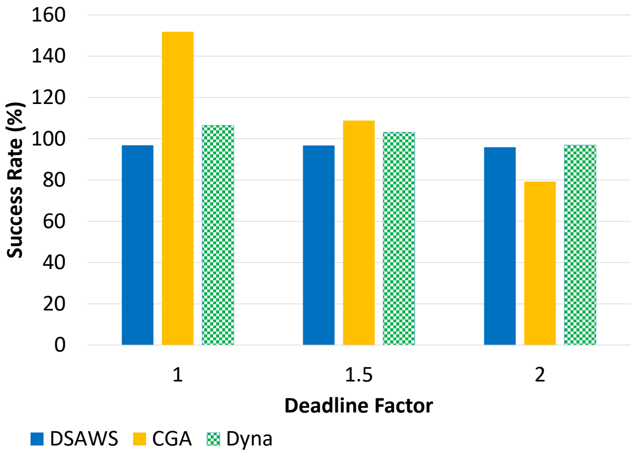

Fig. 10. The makespan of the three algorithms with the Epigenomics application.

in the workflow and executes them to meet the user-specified deadline, as shown in Fig. 8. Also, unlike the other algorithms, DSAWS achieved the cheapest cost among all schedules, as shown in Fig. 9. LIGO has 483 tasks with runtimes greater than the mean execution time (e.g. 227.7). The time difference between tasks can be up to 3 $times$ the mean runtime of the workflow tasks. This results in idle time for other resources and gaps in scheduling between workflow tasks in the case of CGA and Dyna.

In the case of the Epigenomics workflow, the CGA scheduler did not successfully meet the deadline for the strict and moderate deadline factors, but it was able to meet the relaxed deadline factor. Similarly, Dyna has met the relaxed deadline factor but failed to meet the moderate and strict deadline factors. For some Epigenomics tasks, there are significant differences in execution times of 15000 $times$ or even more. Therefore, the CPU performance reduction will significantly impact the processing time of these tasks and lead to delays for CGA and Dyna. The DSAWS algorithm, on the other hand, met all deadlines, as shown in Fig. 10. Furthermore, unlike the other two algorithms, DSAWS has the lowest execution cost, as shown in Fig. 11. This pattern is repeated in Epigenomics experiments, but the time difference can be up to 7 $times$ of the average runtime of the workflow tasks (e.g. 3866.4). Epigenomics has eight levels, with most tasks at level 5 comprising 245 tasks and 99.8% of the total workflow execution time. These differences show that there is a significant need for resources at this level of the workflow for CGA and Dyna.

Finally, the DSAWS algorithm met all the deadline factors of each workflow, while the CGA and Dyna approaches met 25% and 50% of all the deadline factors of all workflows, respectively. These results are consistent with what was expected for each algorithm. The static heuristic (e.g., CGA) was not more successful in meeting deadlines, but the adaptability of Dyna allows it to meet its aim more frequently. The experiment's results also show the efficiency of DSAWS in terms of its ability to produce more cost-effective schedules. DSAWS outperformed all other algorithms we compared it with in all situations. DSAWS succeeds at the lowest cost compared to CGA and Dyna algorithms, regardless of whether the deadline was met or not. Moreover, CGA showcases its ability to generate more cost-effective schedules and surpasses Dyna about 92% regardless of whether the deadline was met or not. For some structures (e.g., CyberShake and Epigenomics),

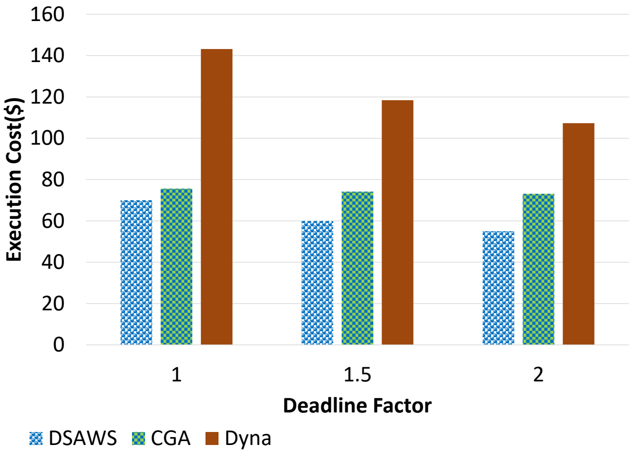

Fig. 11. The execution cost of the three algorithms with the Epigenomics application.

our proposed algorithm uses the initial leased VMs to schedule all tasks of the same workflow to minimise data transfer costs. Other structures (e.g., Montage and LIGO) have many tasks with a short execution time, and many instances of the computation service are launched while only a small part of their time interval is used. Therefore, the proposed algorithm uses the remaining time in the current billing period of the VMs to avoid wasting resources. An additional feature of DSAWS evident in the results is its ability to increase the time required to execute the workflow incrementally. The significance of these relationships is that many users are willing to trade off execution time for lower costs, while others are willing to pay higher costs for faster execution. The algorithm must behave within this logic so that the deadline number is perceived as fair by the users.

V. Conclusion and Future Works

When scheduling workflows in the cloud, resource allocation is important. A good resource estimation method helps the user to reduce the cost and time of workflow execution. Numerous algorithms face the challenge of meeting the user's deadline requirements while minimising the cost of running the workflow. The DSAWS scheduler presented in this paper analyses the structure of the incoming workflow and assigns an optimal resource provisioning mechanism based on the deadline constraint and the rank values of the tasks in the workflow. The main implementation of this algorithm is to make the second phase follow the schedule of the first phase (scheduling of workflow tasks on selected resources). We evaluate the performance of our algorithm by simulating it with four synthetic workflows based on real scientific workflows with different structures. For some structures (e.g., CyberShake and Epigenomics), our proposed algorithm uses the initial leased VMs to schedule all tasks of the same workflow to minimise data transfer costs. Other structures (e.g., Montage and LIGO) have many tasks with a short execution time, and many instances of the computation service are launched while only a small part of their time interval is used. Therefore, the proposed algorithm uses the remaining time in the current billing period of the VMs to avoid wasting resources. The proposed algorithm reduces the overall execution cost of a workflow while achieving a deadline set by the user. Experimental results show that DSAWS outperforms the Dyna and CGA algorithms in terms of meeting workflow deadlines while reducing execution costs. DSAWS met all the deadline factors of each workflow, while CGA and Dyna met 25% and 50%, respectively, of all the deadline factors of all workflows.

In the future, we plan to improve our algorithm to consider the user's deadline and other Quality of Service (QoS) objectives, such as resource utilisation and energy consumption, simultaneously.

Conflict of Interest: The authors declare that they have no conflict of interest.

Prominent Security Vulnerabilities in Cloud Computing

Alanoud Alquwayzani, Rawabi Aldossri, Mounir Frikha
Dept. of Computer Networks and Communications (CCSIT), King Faisal University, Al Hassa 31982, Saudi Arabia

***Abstract*—This research study examines the significant security vulnerabilities and threats in cloud computing, analyzes their potential consequences for enterprises, and proposes effective solutions for mitigating these vulnerabilities. This paper discusses the increasing significance of cloud security in a time characterized by rapid data expansion and technological progress. The paper examines prevalent vulnerabilities in cloud computing, including cloud misconfigurations, data leakage, shared technology threats, and insider threats. It emphasizes the necessity of adopting a proactive and comprehensive approach to ensure cloud security. The report places significant emphasis on the shared responsibility paradigm, adherence to industry laws, and the dynamic nature of cybersecurity threats. The situation necessitates the cooperation of researchers, cybersecurity professionals, and enterprises to proactively address these difficulties. This partnership aims to provide a thorough manual for organizations aiming to bolster their cloud security measures and safeguard valuable data in an ever-evolving digital landscape.**

***Keywords*—Cloud computing; vulnerabilities; cloud security; cloud misconfigurations; data loss; threats**

I. Introduction

Cloud computing has revolutionized how companies manage data and information technology, offering flexible, on-demand resources that facilitate innovation and collaboration. Through services such as Infrastructure-as-a-Service (IaaS), Platform-as-a-Service (PaaS), and Software-as-a-Service (SaaS), businesses of all sizes can now optimize costs, improve agility, and enhance efficiency. Despite its numerous benefits, cloud computing is not without its challenges, particularly in the realm of security. misconfigurations, improper authentication, and phishing attempts are among the many vulnerabilities that have led to significant data breaches and financial losses for organizations [1]. The financial implications of these security vulnerabilities are stark, with the average cost of a data breach reaching $4.24 million in 2023, the highest in 17 years, according to the International Business Machines (IBM) Corporation. Moreover, breaches in cloud environments have proven to be more costly than traditional on-premises intrusions, underscoring the critical need for robust cloud security measures. This study aims to examine the impact of cloud computing vulnerabilities on organizations and review practical mitigation strategies to enhance cloud security. It seeks to explore the advantages and disadvantages of these solutions, considering security and usability trade-offs. The ultimate goal is to contribute to the cloud security literature and provide insights for practitioners and policymakers on safeguarding valuable data in an increasingly digital world.

The rest of the paper is organized as follows: Section II discusses the selection of papers through the PRISMA methodology, followed by a detailed literature review of related works in Section II. Section III presents cloud computing statistics, highlighting its growth and the paradigm shift in organizations. The methodology, including penetration testing and vulnerability scanning, is outlined in Section IV. The paper concludes with a discussion on future trends and a summary of the findings and recommendations in Section V.

II. Literature Review

A. Selection of Papers by PRISMA

This paper aims to conduct a rigorous Systematic Literature Review (SLR) of the existing literature on prominent security vulnerabilities in cloud computing, guided by the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) methodology. PRISMA's transparent, methodological approach ensures an unbiased selection and assessment of the papers, enabling a comprehensive and replicable review. In the first step, the search was conducted in the IEEE Xplore and Google Scholar databases using the querying combination of the following keywords: (Security Vulnerabilities OR Threats) AND Cloud Computing. The literature is restricted to studies published between 2012 and 2023 in English. Google Scholar revealed 8580 papers that discuss security vulnerabilities in cloud computing, specifically focusing on data breaches, unauthorized access, and other security threats. These 8,580 search papers were registered, with 2,000 duplicate papers removed before screening and 4,080 papers excluded for other reasons. Additionally, 29 papers were identified in the IEEE Xplore. Thirteen papers were excluded after screening the title and abstract due to unspecific goals. A total of 157 and 9 papers were assessed for eligibility from the Google Scholar and IEEE Xplore databases, respectively. Finally, after a thorough review and study of these papers, 44 papers were selected from the Google Scholar database and 7 from the IEEE Xplore, making a total of 51 papers selected. This selection process of papers, as conducted by PRISMA, is illustrated in Fig. 1.

B. Related Papers

Cloud computing has a significant role in modern business and individuals' lives. Numerous articles and studies are focused on different literary studies in this field. For instance, a review article written by Alouffi et al. [2] titled "A Systematic Literature Review on Cloud Computing Security: Threats and Mitigation Strategies" identified seven major security threats to cloud computing services, including data tampering and leakage, intrusion of data, and storage of data. Similarly, the paper identifies blockchain as a partnering technology to address some of the security concerns. Akello et al. in [3] summarized existing security surveys in the domains of cloud, fog, and edge computing. The paper underscores the need for

addressing security problems related to these domains while carrying out a comprehensive examination of the different security problems associated with them.

Humayun et al. in [4] in their review paper titled "Cyber Security Threats and Vulnerabilities: A Systematic Mapping Study" included a list of existing studies relating to cyber security vulnerabilities and categorizes them considering the type of a commonly known security threat vulnerability, victim of a cyber threat, vulnerability degree, and method of data collection as well as verification. Another review paper in [5] titled "Security Issues in Cloud Computing: A Review on Security Problems in Cloud Computing—A Survey" also indicated security hurdles like data confidentiality, data integrity, and data privacy.

Numerous other articles exist [6], [5] that offer a comprehensive examination of the diverse security concerns within the realm of cloud computing. These scholarly articles delineate a number of security challenges, including but not limited to issues pertaining to data privacy, data confidentiality, and data integrity. It is imperative to acknowledge that although these articles offer a comprehensive examination of the diverse security concerns in cloud computing, they do not encompass all possible aspects. However, these resources provide a valuable foundation for individuals seeking to further their knowledge on this subject matter. The articles are summarized in the table below:

III. Cloud Computing Statistics

Scalability, flexibility, and cost-efficiency are among the benefits of cloud computing, which is continually growing. However, cloud computing presents severe security issues. Research shows that 90% of cloud data is unstructured and requires different processing and storage methods. This exponential increase is a major issue. Text, photos, audio, video, and other unstructured data have no standard or schema. Unstructured data is harder to manage and secure than structured data. Multi-cloud strategies are growing, with an estimated 87% of companies going multi-cloud by 2024. Multi-cloud setups do, however, also raise the complexity and risk of security breaches, which in 2022 accounted for 45% of all data breaches. The confidentiality, integrity, and availability of cloud data and infrastructure can be jeopardized by security breaches, which can lead to monetary losses, damages to one's reputation, legal ramifications, and regulatory fines. The average cost of these breaches globally was $4.35 million in 2022, and the healthcare industry faced costs as high as $10.10 million. The financial consequences are enormous. In addition, there was a 38% increase in cybersecurity threats between

TABLE I. SUMMARY OF LITERATURE REVIEW PAPERS

Author	Year	Description	Type of Paper
Prabadevi et al. [1]	2014	The paper reviews the list of existing studies relating to cybersecurity vulnerabilities and categorizes them considering the type of a commonly known security threat vulnerability, victim of a cyber threat, vulnerability degree, and method of data collection as well as verification. The authors suggested state-of-the-art techniques for recognizing human emotions from speech, facial expressions, and multimodal signals to address security issues.	Literature Review
Akello et al. [3]	2022	Provides a summary of security surveys in the cloud, fog, and edge computing domains.	Literature Review
Alouffi et al. [2]	2021	The research revealed seven primary security vulnerabilities that pose a risk to cloud computing services. These vulnerabilities include data manipulation and leakage, intrusion, and storage. The study also proposes the utilization of blockchain as a complementary solution to address security concerns.	Literature Review
Humayun et al. [4]	2020	identify available studies on cybersecurity vulnerabilities and categorize these solutions against commonly available security vulnerabilities, victims of cyber threats, vulnerability severity, and data collection and validation methods.	Mapping Study
Patel et al. [7]	2020	The paper overviews cloud security issues, threats, and related attacks.	Literature Review
Kumar et al. [6]	2017	Provide an overview of cloud computing security issues. The paper identifies several security challenges, such as data privacy, confidentiality, and integrity.	Survey
Tabrizchi et al. [8]	2020	Identify several security challenges such as data privacy, confidentiality, and integrity.	Survey
Shaikh et al. [5]	2012	Provides an overview of the various security issues in cloud computing. The paper identifies several security challenges, such as data privacy, confidentiality, and integrity.	Survey
Sharma et al. [9]	2021	The paper proposes a new topology for a single-phase inverter that can reduce the leakage current and increase the efficiency of photovoltaic systems.	Literature Review
Jabir et al. [10]	2016	Th paper presents a framework for conducting penetration testing on a private cloud computing infrastructure.	Research
Shetty et al. [11]	2012	Analyzes the security level of network applications on routers between cloud subscribers and cloud providers.	Research
Kumar et al. [12]	2019	A comprehensive survey focusing on cloud security requirements, threats, vulnerabilities, and countermeasures. It provides an in-depth analysis of cloud computing security challenges and offers a unified taxonomy for security in the cloud environment.	Survey
Sun et al. [13]	2020	This paper analyzes security and privacy protection in cloud computing. It reviews various privacy security issues, access control technologies, and attribute-based encryption (ABE) for cloud security. The paper also explores searchable encryption techniques and integrating various technologies for enhanced privacy and security in cloud computing.	Review
Stergiou et al. [14]	2018	This paper addresses security, privacy, and efficiency in sustainable cloud computing, particularly Big Data and IoT. It explores the integration of cloud computing with IoT technologies and the resulting security challenges while proposing a new system to improve cloud computing security through enhanced network architecture and encryption methods.	Review
Parikh et al. [15]	2019	The paper critically analyzes the unique security and privacy challenges in cloud, fog, and edge computing environments. It discusses the emerging security risks and privacy concerns in these distributed computing models, especially in relation to IoT integration and increasing data traffic. The study also proposes strategic approaches to mitigate these challenges, emphasizing the need for robust security mechanisms tailored to the complexities of interconnected computing systems.	Review
Ahmed et al. [16]	2016	This paper presents a detailed taxonomy for identifying security issues in cloud computing environments. It systematically categorizes various security threats and challenges in cloud computing, offering a structured framework for understanding and addressing these issues. The paper emphasizes the need for comprehensive security strategies to manage cloud security risks' evolving and complex nature.	Taxonomy Review
Guan et al. [17]	2018	The paper explores data security and privacy challenges in fog computing. It critically discusses the unique security and privacy issues that arise due to the nature of fog computing as an extension of cloud computing, especially with regard to IoT applications. The study highlights the need for innovative security approaches due to the limitations of existing cloud computing security solutions in the fog computing paradigm.	Review

2022 and 2023, underscoring the critical need for stronger security protocols to keep bad actors away from cloud data and infrastructure[1]. Phishing, ransomware, Denial-of-Service (DoS), Distributed Denial-of-Service (DDoS), malware, insider threats, and others are cybersecurity attacks. These attacks exploit cloud computing weaknesses such as misconfiguration, inadequate authentication, a lack of encryption, insufficient monitoring, and shared responsibility. Thus, organizations must take a holistic and proactive approach to cloud security that covers data protection, access control, encryption, identity management, threat detection, incident response, compliance management, and more. Some of the aspects under the problem statement are discussed in detail below:

A. Exponential Growth

The use of cloud services by numerous industries and sectors adds to the exponential expansion of cloud data. According to the International Data Corporation (IDC), global public cloud services and infrastructure investment expanded from $229 billion in 2019 to $500 billion in 2023, a 22.3% compound annual growth rate (CAGR). More companies are

[1] https://aag-it.com/the-latest-cyber-crime-statistics/

moving their data and apps to the cloud to maximize its scalability, flexibility, and cost-effectiveness [12]. However, more data is generated, processed, and stored in the cloud, presenting new data management and security challenges. Cloud data grows exponentially due to new technologies and trends that generate large amounts of data. The Internet of Things (IoT) is a network of internet-connected devices that collect and exchange data. Cisco predicted that global IoT connections would rise from 18.4 billion in 2018 to 43.9 billion in 2023, a 19% CAGR. It was also predicted that global IoT data traffic would expand from 14.4 exabytes per month in 2018 to 79.4 by 2023, a 41% CAGR. Since IoT devices have limited storage and processing, most data would be saved and analyzed in the cloud. Another reason driving exponential data expansion in cloud systems is the demand for data analytics and Artificial Intelligence (AI) applications. Organizations can improve customer experiences, processes, and insights with data analytics and AI [12]. The global business intelligence and analytics software market was estimated to expand from $23.1 billion in 2020 to $33.8 billion in 2025, a 7.9% CAGR, according to Gartner. The worldwide AI software market was to expand 33.2% from $22.6 billion in 2020 to $126.0 billion in 2025 [23]. Cloud storage and processing of enormous volumes of data are needed to train and execute these applications. According to IDC's prediction, there is an anticipated CAGR of 12.9% in spending on cloud infrastructure during the period of 2021–2026. This growth is expected to result in a total expenditure of $135.1 billion in 2026, representing 67.3% of the total expenditure on compute and storage infrastructure. The utilization of shared cloud infrastructure is projected to represent 72.3% of the overall cloud capacity, exhibiting a CAGR of 13.8%[2]. The expenditure on specialized cloud infrastructure is projected to see a CAGR of 10.7%, reaching a total of $37.4 billion. Expenditure on non-cloud infrastructure is projected to exhibit a CAGR of 2.3%, ultimately attaining a value of $65.6 billion by the year 2026. It is projected that expenditures made by service providers on compute and storage infrastructure would see a CAGR of 12.1%, ultimately reaching a total of $131.9 billion by the year 2026[3]https://infotechlead.com/cloud/cloud-spending-to-grow-17-to-88-9-bn-in-2022-vs-10-in-2021-idc-74765. This is shown in the graph below.

The global market for AI had a valuation of USD 454.12 billion in 2022 and is projected to reach approximately USD 2,575.16 billion by 2032, exhibiting a CAGR of 19% from 2023 to 2032, as shown below.

B. Paradigm Shift in Organizations

Cloud computing is a multifaceted phenomenon that encompasses both technological advancements and strategic considerations, exerting influence over various aspects of an organization, such as its structure, culture, and performance. Organizations that implement cloud computing can experience several advantages, including enhanced agility, innovation, and collaboration, with decreased operational expenses and complexity. Nevertheless, these organizations also have other obstacles, including the need to adapt to evolving roles and duties, effectively oversee numerous vendors and platforms, and guarantee the protection and confidentiality of data. The shared responsibility model is a fundamental component of cloud security, defining the allocation of security responsibilities between the cloud service provider and the consumer. The level of control and responsibility that customers have over the security of their data and applications varies depending on the specific type of cloud service they are utilizing, either IaaS, PaaS, or SaaS. In the context of IaaS, it is the customer's responsibility to ensure the security of the operating system, applications, data, and network traffic[4]. Conversely, the provider assumes the responsibility of securing the physical infrastructure, virtualization layer, and network. Within the realm of SaaS, the onus of ensuring data security and user access lies solely on the customer. At the same time, the provider bears the responsibility for all other aspects.

An additional crucial element of cloud security is adherence to industry-specific legislation and standards. Examples of these include the Health Insurance Portability and Accountability Act (HIPAA) for the healthcare sector, the Payment Card Industry Data Security Standard (PCI DSS) for the payment card business, and the General Data Protection Regulation (GDPR) for data protection inside Europe. The primary objective of these regulations is to safeguard the confidentiality, integrity, and availability of sensitive data and systems. Nevertheless, these regulations enforce stringent criteria and responsibilities for both the cloud service provider and the customer. As an illustration, it is mandated under the HIPAA that both entities involved must engage in the execution of a business associate agreement (BAA), which outlines their respective obligations and duties pertaining to safeguarding protected health information (PHI)[4]. The GDPR mandates that entities must conform to the fundamental principles of data minimization, purpose limitation, and consent. Hence, enterprises must undertake a comprehensive evaluation of risks and exercise due diligence prior to the selection of a cloud service provider. The user needs to ascertain that the service provider satisfies their security and compliance prerequisites while also offering transparency and accountability in their service provisions[5]. In addition, it is imperative for organizations to consistently engage in monitoring and auditing of their cloud infrastructure in order to identify and address any possible security risks or occurrences promptly. Therefore, cloud computing represents a significant shift in the prevailing paradigm, presenting numerous advantages and posing various obstacles for enterprises. Conducting research is necessary in order to comprehensively comprehend and efficiently tackle these difficulties[6]. Organizations may effectively use the capabilities of cloud computing while mitigating potential dangers by adhering to established best practices and standards in cloud security and compliance.

C. Security Vulnerabilities

In 2022, a significant proportion of data breaches were attributed to infiltrations into cloud-based systems. This emphasizes the pressing necessity of promptly addressing the

[2] https://solutionsreview.com/data-management/80-percent-of-your-data-will-be-unstructured-in-five-years/

[4] https://www.crowdstrike.com/cybersecurity-101/cloud-security/cloud-vulnerabilities/

[5] https://www.cloudvulndb.org/

[6] https://www.cypressdatadefense.com/blog/cloud-computing-security-vulnerabilities/

distinct security risks that impact cloud environments. The vulnerabilities encompass a wide range of issues, including misconfigurations in cloud settings, inadequate user access controls, weaknesses in the architecture of cloud service providers, and advanced attack methodologies. Conducting research in this field is crucial for the identification of these vulnerabilities and the formulation of efficient strategies to protect sensitive data within businesses. Misconfigurations are identified as a primary contributing factor to data breaches occurring within cloud infrastructures[7]. Cloud services provide a wide range of choices, and enterprises frequently have difficulties configuring them in a secure manner. Misconfigurations have the potential to inadvertently expose data to unauthorized access, leakage, or alteration. Research can yield significant insights into prevalent misconfigurations and effective preventive measures. The infrastructure of cloud service providers represents an additional factor contributing to vulnerability. The security of data stored in cloud environments is frequently contingent upon the security measures implemented by the cloud service provider. Hence, it is vital to comprehend the prospective vulnerabilities within the provider's infrastructure and their potential impact on the data. Research also plays a crucial role in enabling enterprises to effectively monitor and stay updated on the most recent vulnerabilities. This allows them to ensure that cloud providers swiftly patch these issues. Furthermore, it is important to note that, with the continuous evolution of cyber threats, conducting research in this particular domain might provide valuable insights into emerging attack strategies and vulnerabilities that are unique to cloud computing. The acquisition of this knowledge is crucial for enterprises to adopt a proactive approach to safeguarding their data against developing dangers. Different scholars assert that it is important to enable firms to identify and address many types of attacks, including cryptojacking, denial-of-service, and server-side request forgery, within their cloud settings. It is imperative to note that the duty to ensure security in cloud computing is a collaborative effort between enterprises and cloud service providers. Gaining insight into the allocation of this responsibility and acquiring knowledge about successful collaboration are essential elements in the process of mitigating security vulnerabilities in cloud computing.

The exposed data included sensitive information such as authentication credentials, secret API data, and decryption keys. Moreover, documents contained in these servers revealed that the databases were storing data for Accenture's clients, including high-profile telecommunication companies and other Fortune 100 firms. The breach could expose Accenture and its clients to significant risks, including unauthorized data manipulation, fraud, and targeted phishing attacks. Fortunately, the exposed databases were discovered by a security researcher before any known malicious exploitation could occur. This incident underlines the critical need for stringent security practices in cloud storage configuration. The primary lesson here is the importance of regular security audits and implementing strict access controls. Companies must ensure their cloud services are correctly configured and regularly monitored for potential vulnerabilities.

The 2022 Thales Cloud Security Report by 451 Research, part of S&P Global Market Intelligence, found that 45% of businesses had a cloud-based data breach or failed audit in 2021, up 5% from 2020, raising increased concerns about cybercrime. Cloud adoption, especially multicloud usage, is rising globally. In 2021, enterprises worldwide used 110 SaaS apps, up from eight in 2015. 72% of enterprises now use multiple IaaS providers, up from 57% in 2021. One in five (20%) respondents use three or more providers, virtually doubling in 2021. Despite their growing popularity, businesses worry about the complexity of cloud services, with 51% of IT experts saying cloud privacy and data protection are harder. Complexity necessitates stronger cybersecurity. Most respondents (66%) reported that 21–60% of their sensitive data resides in the cloud. Only 25% indicated they could classify all the data. About 32% of respondents had to notify a government agency, client, partner, or employee of a breach. This should worry sensitive data-holding companies, especially in highly regulated industries. Cyberattacks continue to threaten cloud apps and data. Malware, ransomware, and phishing/whaling assaults increased for 26%, 25%, and 19% of respondents, respectively. IT professionals consider encryption essential for multicloud data protection. Most respondents use encryption (59%) and key management (52%) to secure cloud data. When asked how much of their cloud data is encrypted, just 11% replied 81–100%. Enterprises may also face key management platform sprawl. 10% utilize one to two platforms, 90% use three or more, and 17% use eight or more. Enterprises should prioritize cloud data encryption[8]. The practical usefulness of encryption platforms was shown when 40% of respondents said they avoided breach reporting because the stolen or leaked data was encrypted or tokenized. Positive signals of businesses investing in Zero Trust were also promising. About 29% of respondents are actually implementing a Zero Trust strategy, 27% are analyzing and developing one, and 23% are contemplating it. This is encouraging, but there is potential for improvement.

D. Financial Ramifications

The occurrence of data breaches inside cloud computing environments can result in major monetary losses for enterprises, impacting their immediate and sustained operational outcomes. Based on a report published by IBM, it has been determined that the worldwide mean expense associated with a data breach in the year 2023 amounted to USD 4.45 million, reflecting a 15% escalation over a span of three years[9]. Nevertheless, the financial implications of a data breach exhibit considerable disparity, contingent upon the geographical location and sector of the afflicted entity[10]. In addition to comprehending the possible financial implications associated with data breaches, it is imperative for enterprises to adopt proactive measures aimed at the prevention and mitigation of such incidents. According to a survey published by IBM, the utilization of security AI and automation has the potential to yield a reduction in the average cost of a data breach by USD 1.76 million in comparison to firms that do not employ these technologies. The implementation of security AI and

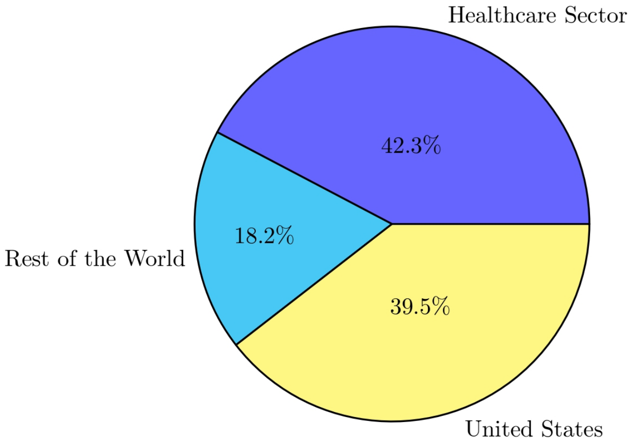

Fig. 2. The most affected sectors.

automation within businesses can contribute to the expedited identification and mitigation of potential threats, thereby reducing the adverse consequences of security breaches. In addition, it is advisable for firms to adopt comprehensive cybersecurity insurance policies, as they can provide coverage for the financial ramifications that may arise from security breaches. It is recommended that organizations allocate resources towards the implementation of cybersecurity training and awareness programs.

These initiatives aim to mitigate human errors and insider threats, which are prominent factors contributing to data breaches. By adhering to these suggestions, firms can enhance their readiness for the financial consequences associated with data breaches in cloud computing and mitigate their financial losses[11]. Data breaches can potentially lead to significant ramifications for the financial viability and long-term viability of companies as shown in Fig. 2 the healthcare sector has the lion's share of being attacked. However, these breaches can be averted and alleviated by implementing appropriate security measures and strategic investments. Conducting research in this domain can assist firms in making well-informed decisions pertaining to their cybersecurity strategy and policies.

E. Escalating Cybersecurity Attacks

The observed surge in cybersecurity attacks throughout the period spanning from 2022 to 2023 highlights the dynamic nature of the threat environment, as shown in Fig. 3. Conducting research in this domain is crucial in order to investigate the characteristics of these attacks and provide efficacious strategies to mitigate their impact. The complexity and variety of cyberattacks are increasing, incorporating a wide array of strategies like ransomware, zero-day flaws, social engineering, and supply chain attacks [18]. In recent years, there has been a notable increase in the occurrence and financial impact of ransomware attacks. Such attacks consist of an initial encryption of the victim's data before requesting a monetary ransom for the release of the hijacked information. In terms of ransomware expenditure, according to a survey by IBM in 2023, the global average expenditure was USD 5.66 million, a whopping hike of 21% from 2022. Zero-day exploits have increasingly seen their occurrence and impact. The menace this trend poses to critical infrastructure and the nation's security is substantial. These social engineering attacks are becoming more sophisticated and targeted, taking advantage of the growing use of social media and online environments. They are aimed at psychological tricks that would induce people to give out private data or engage in dangerous acts. Supply chain attacks that compromise software and hardware components from trustworthy vendors and partners pose serious challenges to firms. The assaults are capable of affecting different entities within several sectors. It is imperative for organizations to comprehend the dynamic strategies and underlying incentives driving these attacks. Research can provide valuable insights into the methods, techniques, and processes employed by cybercriminals, enabling firms to formulate proactive security plans. Research plays a crucial role in enabling companies to discern the indicators of compromise and the assault vectors employed by diverse threat actors, along with comprehending their goals and objectives.

Research can also aid firms in comprehending the behavioral and psychological elements that impact consumers' vulnerability to social engineering attacks, as well as in devising proficient awareness and education initiatives to alleviate such risks. Moreover, the proliferation of remote work and the use of cloud-based services have resulted in the expansion of the attack surface, hence heightening the susceptibility of enterprises to cyber threats. Research plays a crucial role in enabling firms to discern the precise issues presented by these transformations and formulate effective methods to safeguard remote and cloud-based operations. This encompasses the enhancement of identity and access management, the implementation of multi-factor authentication, and the improvement of threat detection and response capabilities. Research can additionally aid organizations in assessing the security stance and adherence to regulations of their cloud service providers, as well as establishing explicit roles and duties for the governance of cloud security [18]. The establishment of partnerships and cooperation among researchers, cybersecurity professionals, and other organizations is crucial to proactively addressing the increasing frequency and severity of cybersecurity threats. The dissemination of knowledge regarding emerging threats and vulnerabilities has the potential to facilitate the creation of enhanced security measures[12]. The investigation conducted in this field has the potential to make a valuable contribution to the collaborative endeavor of protecting data and systems in an ever more hostile digital environment.

F. Gap in Existing Literature

Cloud computing is a conceptual framework that presents a multitude of advantages, including scalability, elasticity, and cost-effectiveness. However, it also presents notable security obstacles. The presence of security vulnerabilities within cloud computing has the potential to jeopardize the confidentiality, integrity, and availability of both cloud services and data. This, in turn, can result in significant ramifications for both suppliers and users of cloud services. Hence, it is important to ascertain and evaluate the key security risks in cloud computing and put

[11] https://newsroom.ibm.com/2023-07-24-IBM-Report-Half-of-Breached-Organizations-Unwilling-to-Increase-Security-Spend-Despite-Soaring-Breach-Costs

[12] https://onlinedegrees.sandiego.edu/top-cyber-security-threats/

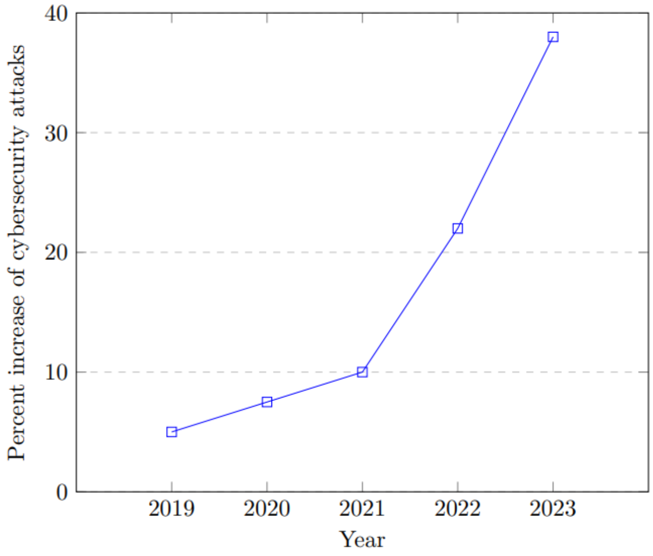

Fig. 3. Frequency increase of cybersecurity attacks between 2019 and 2023.

forth effective mitigation strategies. Nevertheless, the current body of scholarly work pertaining to cloud security is characterized by fragmentation and dispersion. It predominantly concentrates on specific aspects or domains of cloud security while lacking a comprehensive and methodical examination that encompasses the diverse security vulnerabilities, their ramifications, and the corresponding remedies within a unified and coherent analysis. The objective of this study is to address the aforementioned deficiency by undertaking a comprehensive examination of existing literature, known as a SLR, to identify and analyze the major security vulnerabilities present in cloud computing. A SLR is a methodological approach characterized by its rigorous and transparent nature that aims to locate, evaluate, and synthesize the available body of knowledge pertaining to a certain subject. This study aims to utilize the SLR approach to present a thorough and current examination of the existing research on vulnerabilities in cloud security. Additionally, it seeks to identify areas where further research is needed and suggest potential future directions in this field. This study aims to investigate the primary security issues associated with cloud computing, including questions: What are the ramifications of these security vulnerabilities for cloud service providers and their clientele? What are the productive mitigation solutions for these security vulnerabilities?

IV. Cloud Computing Security Assessment

A. *Impact of Security Vulnerabilities in Cloud Computing*

Cloud computing refers to providing various computing services, including storage, servers, databases, networking, software, analytics, and intelligence, through the Internet. Cloud computing has numerous advantages for both enterprises and individuals, encompassing scalability, cost-effectiveness, performance, reliability, and innovation. Nevertheless, the advent of cloud computing also presents novel security concerns and hazards that necessitate attention and resolution from both cloud service providers and their clientele[13]. Security vulnerabilities refer to inherent weaknesses or deficiencies inside a given system or application that can be potentially exploited by malicious actors with the intention of compromising the system's confidentiality, integrity, or availability, as well as the data it houses. Security vulnerabilities can result in significant consequences for both cloud providers and their clients[14]. These consequences include, but are not limited to, data breaches, financial losses, legal liability, reputational harm, and operational disruptions. The following are the impacts of security vulnerabilities in cloud computing:

1) Cloud misconfiguration: Cloud misconfiguration is a prevalent security vulnerability that occurs in cloud computing. Cloud misconfiguration refers to the situation in which a cloud resource or service is not appropriately configured in accordance with established security best practices or regulations. An instance may arise if a cloud storage bucket is inadvertently made accessible to the general public on the internet, hence enabling unauthorized individuals to get entry to confidential information[15].

Alternatively, a cloud user may possess an abundance of permissions or privileges that exceed the requirements of their designated position or function. Human error, a lack of knowledge base, or insufficient automation can all lead to cloud misconfiguration. Misconfigured clouds can have detrimental effects on both cloud service providers and users, including: Data breaches: Cloud misconfigurations may lead to data breaches wherein unauthorized individuals may access, steal, alter or delete confidential data stored in the cloud[16]. Data breaches can have adverse financial implications, legal obligations, government sanctions, and loss of the reputation of the customers and the cloud service providers themselves. Compliance violations: Cloud misconfiguration leads to non-compliance instances where cloud providers or clients cannot observe security standards or obligations enshrined in laws, rules, contracts, or industry frameworks. Non-compliance instances may attract fines, regulatory actions, legal proceedings or lack of confidence for cloud service providers and their customers.

Operational disruption: Cloud service/application availability and performance may be impacted by cloud misconfiguration. For example, a firewall that is not properly configured can block the lawful traffic network, and a load balancer that is not properly configured can cause the quality of service degradation. Operational disruption can cause customer dissatisfaction, reduced revenues, and diminished competitive advantage to cloud providers and their clients.

To prevent or mitigate cloud misconfiguration, cloud providers and customers should follow some best practices, such as:

a) Enforce the principle of least privilege: The principle of least privilege suggests that each user or service should possess only the essential level of access or permissions necessary to carry out their designated tasks. The use of this measure

[13] https://www.wiz.io/academy/common-cloud-vulnerabilities

[14] https://www.orientsoftware.com/blog/vulnerability-in-cloud-computing/

[15] https://www.trendmicro.com/vinfo/us/security/news/virtualization-and-cloud/the-most-common-cloud-misconfigurations-that-could-lead-to-security-breaches

[16] https://www.techtarget.com/searchsecurity/definition/data-breach

can effectively decrease the attack surface and mitigate the potential extent of harm in the event of a security breach.

b) Use third-party tools: Third-party technologies can scan and identify instances of cloud misconfiguration, as well as offer advice or remedial measures. One illustration of how a cloud-native application protection platform (CNAPP) might enhance the visibility and security of cloud resources can be observed.

c) Review and audit regularly: Regular evaluation and auditing of cloud configurations by both cloud providers and clients is critical to ensuring adherence to security policies and best practices. In addition, it is essential for individuals to diligently oversee and record any modifications or actions pertaining to their cloud-based assets, with the purpose of identifying any irregularities or occurrences.

2) Data leakage: Data leakage is a prevalent security risk that is frequently seen in the realm of cloud computing. Data leakage is the unintended or purposeful transfer of data from a secure source to an unauthorized destination[17]. Unencrypted communication lines, unsecured APIs, employees with ill-intent within the organization, hacked passwords, third party dependencies may be potential data leakage avenues.

Data leakage is a serious threat for cloud service providers and their clients. These risks involve data breaches, which can lead to monetary losses, legal issues, fines, and damage to one's reputation. Also, it is worth mentioning that privacy breaches occur when the personal or confidential data is divulged without the due authority, therefore leading to identity theft, fraud, or harassment. Lastly, an unregulated data leakage is also capable of destroying a company's competitive advantage by revealing sensitive information such as secret knowledge, business strategies, or important assets to competitors. It is important to follow the current best practices in order to prevent or mitigate these risks. This involves putting up several security measures to make sure that the data is not accessed by individuals without authority to do so. These measures include encrypting data both when it is stored and when it is being transmitted, using secure application programming interfaces (APIs) that comply with recognized security standards, and deploying data loss prevention (DLP) solutions to identify, categorize, and safeguard sensitive data. Additionally, access and usage policies are enforced across both cloud-based and on-premise environments.

3) Shared technology vulnerabilities: The presence of shared technology vulnerabilities in cloud computing arises from the fundamental utilization of common infrastructure, platforms, and software for the provision of services to numerous consumers. Consequently, any flaw present in the shared technology possesses the capacity to pose a possible threat to all users. These vulnerabilities have the potential to result in data breaches, which can expose sensitive information and result in financial losses, legal consequences, and reputational damage for both service providers and customers.

Furthermore, these entities have the potential to interfere with many services, exemplified by their involvement in denial-of-service assaults, resulting in the deterioration or complete cessation of these services. Resource abuse is a significant worry in the realm of cybersecurity since malevolent actors exploit communal technology for illicit objectives, resulting in escalated expenses, diminished operational efficiency, and compromised availability [19]. In order to address these risks, it is imperative for both cloud providers and clients to adhere to established best practices. These include timely patching and update, resource isolation, segregation. Also, constant tracking and auditing should ensure prompt detection of irregularities or any breach in the security.

4) Insecure interfaces and APIs: Cloud computing security is a great problem due to insecure interfaces and APIs. The communication and interaction between the services are done through these interfaces and APIs, but if the interfaces or the APIs are poorly designed and also not secured, then they can be the biggest dangers that a system may have. They could arise through weaknesses in authentication, inappropriate encryption, ineffective input validation, and poor error handling [18]. The potential outcomes of these vulnerabilities might have significant ramifications, such as instances of data breaches where confidential data may be illicitly accessed, pilfered, altered, or erased. This can lead to financial detriments, legal implications, regulatory penalties, and reputational harm for both cloud service providers and their clientele[19]. Furthermore, service disruptions like DDoS attacks can have an impact on the availability and performance of cloud services and apps.

In summary, the exponential expansion of cloud computing has undeniably revolutionized the manner in which enterprises manage their data and information technology requirements, presenting a multitude of benefits in relation to adaptability, availability, and cooperation. Nevertheless, this paradigm shift has concurrently presented a plethora of security concerns and vulnerabilities that necessitate resolution in order to safeguard confidential information and uphold the authenticity of cloud infrastructure.

B. Cloud Security Assessment Techniques

1) Penetration testing: Penetration testing is a technique employed to assess the security of a cloud environment by emulating an attack originating from a malevolent entity. This process facilitates identifying familiar and unfamiliar vulnerabilities inside the cloud environment, encompassing misconfigurations, inadequate authentication mechanisms, insecure Application Programming Interfaces (APIs), data breaches, and more security weaknesses. It contains five stages, as shown in Fig. 4. By identifying vulnerabilities that malicious actors could exploit, penetration testing provides valuable insights and suggestions for improving the security posture and resilience of the cloud environment.

Penetration testing can be conducted at several levels inside the cloud environment, including the network, application, data, and user layers. Penetration testing can be undertaken from several perspectives, including black-box, white-box, or gray-box, depending on the test's scope and objectives. Black-box testing emulates the actions of an external adversary

without prior knowledge of the cloud environment. White-box testing involves emulating an internal attacker who possesses comprehensive access to and understanding of the cloud infrastructure. Gray-box testing involves emulating a partially informed adversary with restricted access to or understanding of the cloud infrastructure.

An example of penetration testing within cloud computing is the AWS Penetration Testing service. This service enables customers to seek authorization to conduct permitted tests on their AWS resources. An additional illustration may be in the form of IBM X-Force Red Vulnerability Management Services. This service provides a comprehensive methodology for cloud penetration testing, encompassing many aspects such as infrastructure, apps, data, and users. In our research, penetration testing is critical for assessing cloud security vulnerabilities. This methodology is informed by the insights provided by Vasenius (2022) in his thesis “Best Practices in Cloud-Based Penetration Testing.” Vasenius’ comprehensive analysis of cloud-specific penetration testing approaches, tools, and best practices offers a valuable framework for our penetration testing strategy, particularly in the context of cloud environments and their unique security challenges[20].

In 2022, Khuong et al. in [20] studied a novel architectural approach called deep cascaded reinforcement learning agents (CRLA). This approach was developed to tackle the challenge of large discrete action spaces in an autonomous penetration testing simulator. In such simulators, the number of available actions grows exponentially as the complexity of the cybersecurity network being tested increases. Using an algebraic action decomposition strategy, the Comparative Reinforcement Learning Algorithm (CRLA) demonstrates superior efficiency and stability in determining the optimal attack policy in scenarios characterized by extensive action spaces. This outperforms the conventional deep Q-learning agent, frequently employed as an artificial intelligence approach for autonomous penetration testing.

In 2023, a research paper by Hu et al. in [21] introduced a precise grey box penetration testing methodology known as TAC. This strategy aims to identify instances of identity and access management (IAM) vulnerabilities and privilege escalation (PEs) in third-party services. Third-party cloud security services are frequently employed to identify potential PEs resulting from misconfigurations in IAM. In order to address the dual issues of labor-intensive anonymizations and potential exposures of sensitive information, TAC engages with consumers through a selective querying approach that focuses solely on the relevant information required. The primary finding of this article is that the IAM configuration contains a limited amount of pertinent information for the detection of IAM PE. This study introduces the concept of IAM modeling, which allows for detecting a wide range of IAM PEs by utilizing the limited information obtained from queries. In order to enhance the effectiveness and versatility of TAC, our objective is to reduce customer contacts by implementing Reinforcement Learning (RL) in conjunction with Graph Neural Networks (GNNs). This integration enables TAC to acquire the ability to minimize the number of queries made.

Our approach to penetration testing, especially in the context of mobile cloud computing, is informed by the findings and methodologies discussed by Bakar et al. in [22] provided a comprehensive overview of penetration testing techniques and best practices tailored for mobile cloud environments, which is particularly relevant for our research as it addresses the unique challenges and considerations in these settings. Our penetration testing methodology is significantly influenced by the groundbreaking work of Vuggumudi et al. in [23] outlined an innovative approach known as Compliance Based Penetration Testing (CBPT), specifically tailored for PaaS environments. This approach underscores the importance of a collective approach to security in cloud services, highlighting the necessity for ongoing monitoring and compliance-aligned testing. Such an approach is vital for our research, considering the ever-changing landscape of cloud environments and the continuous evolution of regulatory requirements.

2) Vulnerability scanning: Vulnerability scanning is a technique of systematically discovering, assessing, and reporting security vulnerabilities in a cloud environment and It goes through five stages as shown in Fig. 4. It helps enterprises uncover gaps in their cloud services, infrastructure, and applications that potentially threaten the confidentiality, integrity, or availability of their data and resources. Vulnerability scanning also helps firms comply with security standards and regulations, such as PCI DSS, HIPAA, GDPR, and more. Vulnerability scanning can be performed using numerous tools and approaches, such as automatic scanners, human audits, code reviews, or ethical hacking. Vulnerability scanning can be split into two types: active and passive. Active scanning involves sending probes or queries to the cloud environment to find vulnerabilities and measure their impact. Passive scanning involves monitoring the network traffic or records of the cloud environment to find vulnerabilities and irregularities.

An example of vulnerability scanning in cloud computing is AWS Amazon Inspector, which is an automated security evaluation tool that helps clients enhance the security and compliance of their AWS applications[21]. Another example is

[20] https://www.utupub.fi/handle/10024/173476

[21] https://docs.aws.amazon.com/inspector/latest/user/what-is-inspector.html

Digital Defense Frontline VM, which is a cloud-based vulnerability management tool that delivers continuous scanning and reporting of cloud assets. Our research methodology for vulnerability scanning incorporates insights and techniques from Mitchell and Zunnurhain's (2019) study, "Vulnerability Scanning with Google Cloud Platform," presented at the CSCI conference [24]. This paper presents a detailed examination of vulnerability scanning methods within the Google Cloud Platform, offering a specific lens on how these scans can be effectively utilized in cloud-based environments. Their work provides a valuable perspective on the practical applications and challenges of conducting vulnerability scans in such settings, directly relevant to our research focus.

We have heavily referenced the comprehensive analysis by Kritikos et al. [25] that meticulously evaluated the latest tools and databases pertinent to vulnerability assessment in the cloud. The survey's detailed insights into these tools' performance, range, and functionalities significantly influence our methodology, particularly in selecting and implementing the most effective techniques for extensive vulnerability scanning in cloud-based applications.

C. Future Trends in Cloud Computing Security

As cloud computing evolves, staying ahead of emerging security challenges is crucial. Cloud security landscape is expected to undergo significant changes in the coming years, influenced by technological advancements and shifts in cyber threats. Below are key trends that are likely to shape the future of cloud computing security:

1) Increased reliance on AI and Machine Learning (ML): AI and ML are set to play a pivotal role in cloud security. These technologies can analyze vast amounts of data to identify patterns indicative of cyber threats, enabling proactive threat detection and response. As cyberattacks become more sophisticated, AI-driven security systems will be critical in identifying and neutralizing threats before they can cause damage[26].

2) Greater emphasis on zero trust architectures: The traditional security model of 'trust but verify' is shifting towards a 'never trust, always verify' approach. Zero Trust Architecture (ZTA) will become more prevalent, where security protocols require verification from everyone attempting to access resources in the network, regardless of whether they are inside or outside the network perimeter. This approach minimizes the risk of internal threats and data breaches [27].

3) Expansion of edge computing: As the Internet of Things (IoT) expands, edge computing will become more common, processing data closer to where it is generated rather than in a centralized cloud-based data center. This shift will require new security strategies to protect data across more dispersed networks[22].

4) Enhanced regulatory compliance: With the growing concern over data privacy and security, regulatory compliance will become more stringent. Companies must adapt to these regulations, which will likely require more robust security measures to protect sensitive data, especially in industries like healthcare and finance [28].

5) Blockchain for improved security: Blockchain technology is expected to be increasingly adopted for cloud security because it offers decentralized security and reduces single points of failure. Its potential for ensuring data integrity and preventing tampering will make it a valuable tool in enhancing cloud data security[23].

6) Rise in cybersecurity mesh: Cybersecurity mesh is a flexible, modular approach that integrates various security services. This trend will allow organizations to deploy and integrate security where it's most needed and manage it in a more unified way, thus improving the overall security posture[24].

V. Conclusion

Cloud computing has rapidly changed how firms manage their data and IT demands, providing flexibility, accessibility, and cooperation. This change has also revealed many security risks that must be addressed to secure sensitive data and cloud settings. Mismanaging cloud resources or data frequently results in cloud misconfiguration and data leakage. These vulnerabilities can cause data breaches, compliance violations, and financial losses for cloud providers and clients. Additionally, cloud-based shared technological vulnerabilities are risky. Cloud computing allows numerous enterprises to share infrastructure and platforms, which can expose sensitive data to breaches, service outages, and resource misuse if not properly secured. Quick patching, resource isolation, and monitoring can mitigate these shared vulnerabilities. Furthermore, understanding the shared responsibility concept is crucial. This model defines cloud service providers and customer security duties. Organizations must know how to secure their cloud resources and data and use cloud providers' tools and services to improve security. Cloud services and emerging technologies like IoT and AI drive exponential data growth in cloud environments, creating unique problems. Securing varied cloud environments becomes more difficult as firms adopt multi-cloud strategies. Cloud data security and compliance need risk assessments, careful cloud service provider selection, and industry-specific requirements. Ransomware, zero-day exploits, social engineering, and supply chain assaults are becoming more sophisticated, requiring cybersecurity specialists, corporations, and researchers to share knowledge and information. To succeed in this changing world, enterprises must take a proactive, holistic approach to cloud security, covering technological and organizational factors. In an ever-changing digital world, organizations may protect their data, manage risks, and maintain their reputation and financial stability by remaining educated about new threats and vulnerabilities, applying best practices, and enhancing their cloud security maturity.

DDoS Attacks Detection in IoV using ML-based Models with an Enhanced Feature Selection Technique

Ohoud Ali Albishi, Monir Abdullah*
College of Computing and Information Technology
University of Bisha
Bisha 67714, Saudi Arabia

***Abstract*—The Internet of Vesicles (IoV) is an open and integrated network system with high reliability and security control capabilities. The system consists of vehicles, users, infrastructure, and related networks. Despite the many advantages of IoV, it is also vulnerable to various types of attacks due to the continuous and increasing growth of cyber security attacks. One of the most significant attacks is a Distributed Denial of Service (DDoS) attack, where an intruder or a group of attackers attempts to deny legitimate users access to the service. This attack is performed by many systems, and the attacker uses high-performance processing units. The most common DDoS attacks are User Datagram Protocol (UDP) Lag and, SYN Flood. There are many solutions to deal with these attacks, but DDoS attacks require high-quality solutions. In this research, we explore how these attacks can be addressed through Machine Learning (ML) models. We proposed a method for identifying DDoS attacks using ML models, which we integrate with the CICDDoS2019 dataset that contains instances of such attacks. This approach also provides a good estimate of the model's performance based on feature extraction strategic, while still being computationally efficient algorithms to divide the dataset into training and testing sets. The best ML models tested in the UDP Lag attack, Decision Tree (DT) and Random Forest (RF) had the best results with a precision, recall, and F1 score of 99.9%. In the SYN Flood attack, the best-tested ML models, including K-Nearest Neighbor (KNN), DT, and RF, demonstrated superior results with 99.9% precision, recall, and F1-score.**

Keywords*—*Random forest; IoV; DDoS; feature selection

I. Introduction

After the significant development in the number of vehicles, where it was found that there are one billion vehicles around the world, with an expected doubling by 2035, and the accompanying increase in congestion and traffic accidents, driving has become difficult and dangerous. The idea of the IoV has been formulated to address these challenges. IoV is at the heart of the new generation of intelligent transport systems, representing a new trend of future development. The IoVs is defined as a distributed network with an open, integrated, and credible system that provides a safe and smart environment. This system consists of vehicles, individuals, infrastructure, and networks related to smart systems. It depends on the sensors integrated into modern vehicles, which are linked to the intelligent transport network. Initially, the VENAT network was allocated with its limited ability to use the information provided by mobile devices. Currently, in the 5G era, the IoV has evolved, and its ability to deal with data during communication between vehicles and the network, vehicles with each other, or vehicles with people has significantly improved. In our opinion, safeguarding the communication between vehicles and achieving a more effective network requires the use of ML techniques to provide the necessary protection for wireless communications and efficient detection of attacks, as well as the detection of misconduct and the concept of trust. It provides electronic security services for road services, vehicles, and the information required to enhance security operations and take proactive steps against threats [1]. IoV networks are characterized by many features such as scalability, dynamic topology changes, variable network density depending on city conditions, geographical location energy, security, and privacy. The IoVs involves massive dynamic data, making security and privacy major concerns. One of the most significant challenges in reducing penetration is security and privacy. Types of security attacks include authentication attacks such as jamming, eavesdropping, and Sybil attack. As a consequence, constructing a protection system based on ML techniques, algorithms, and strong authentication is required to maintain anonymity traceability, and wireless communication protection attributes to connect securely and effectively [2]. The main contribution of this research are:

1) Developing a ML based system to prevent communication errors that could cause traffic disruptions or accidents between networks and interconnected vehicles.
2) Developping IoV protection technologies and increased security investment.
3) Ensuring the security for vehicle exchange data storage and infrastructure.

The rest of the paper is organized as follows: Section II presents related work. In Section III, describes Proposed models. Section IV presents our implementation and experiments. Section V presents an experimental evaluation of the performance our heuristic. Section VI concludes the paper and discusses some future work.

II. Related Works

A. Internet of Vehicles (IoVs)

The IoV appeared as a new attempt with the emergence of Ion technologies in the field of wireless cooperation with the

[*] Corresponding authors

emergence of the Internet of Things (IoT). It is a common complex network in which real communication takes place in the IoV between two or more entities in which many different technologies are used such as the navigation system, mobile, sensors, and the instruction system. IoV has gone through stages with a history of innovation and development through modifications in size, style, and decoration, while technological improvement has pushed mobile phones for cars to the latest trends. Analytical approaches have improved IoV's understanding of traffic and telemetry trends. Advances in information systems, detection and communication capabilities, and intelligent physical infrastructure create new opportunities to reduce real congestion and response challenges. Real-world data flows ingest a heterogeneous amount of data and drive data processing and secure transmission between entities based on this data. Vehicles are controlled and directed in realtime [1]. Analytical approaches have improved IoV's understanding of traffic and telemetry trends. Advances in information systems, detection and communication capabilities, and intelligent physical infrastructure create new opportunities to reduce real congestion and response challenges. Real-world data flows ingest a heterogeneous amount of data and drive data processing and secure transmission between entities based on this data. Vehicles are controlled and directed in real- time [1].

B. IoV Architecture

The IoV architecture is composed of four main layers: environment detection, network, computation, and application layer. The environmental detection layer is tasked with collecting data from the environment around the vehicle, such as object locations, road conditions, and driving habits, via an RFID card and sensors embedded inside vehicles. The network layer is responsible for providing all required types of connectivity, such as short-term communication (for example, Zigbee, Bluetooth, Wi-Fi) or cellular network (for example, WiMAX or 4G/LTE), between the objects of the vehicle's environment and its connection to the cloud. The computing layer is accountable for processing, storing, and resolving the collected data necessary to provide safety, comfort, risk situations, and efficiency. The application layer offers both open and closed services. Open services refer to online applications provided by Internet service providers and third-party service providers (for example, real-time traffic services and online video delivery). In contrast, closed services refer to a particular IoV application (for example, a control panel and traffic instructions) [3].

C. Characteristics of IoV

- High Scalability: A city can contain millions of vehicles and sensors that require an extensive network. This network must be scalable to accommodate the continuous increase of vehicles.
- Dynamic structure: Many components of an IoV interact with each other (particularly vehicles) moving at high speed, rapidly changing the network topology.
- Geocommunication: The vehicle network uses geocommunication, but in IoV nodes are not predetermined when packets are sent and their speed varies based on the geographical area of the sites [4].

D. Attack Types in IoV

IoV security is a highly developed field that requires serious attention. Any simple mistake or security failure can cause a catastrophe in terms of human and economic losses, causing damage to vehicles and road infrastructure.

1) Authentication attacks Sybil Attack: The Cyber node detects the imposition of an attack as it damages the systems in the wireless network and thus increases the likelihood of leakage of vehicle data [5], [6]. GPS deceives: This type of attack by giving deceptive information regarding vehicle speed and geographic location data of other vehicles as undeniable evidence and thus helps to avoid tracing causing unpredictable damage to property and providing false evidence [7].
2) Disguise attacks. In the network environment, each entity has its identity, in disguise attacks a similar identity is given to several nodes simultaneously causing chaos in IoV systems [2].
3) Availability attacks. Availability attacks are the main objective. These attacks is to decrease transmission power and bandwidth and thus collapse the IoV system by controlling or destroying it completely to make a significant impact on the IoV system [2].
4) Eavesdropping attacks. Resource and data are the main components of the vehicle internet system and therefore care must be taken of sensitive data and that unreliable nodes connect to it. In this type of attack, the data is stolen by intercepting and eavesdropping on it [4].
5) Jamming attacks. These are interference attacks. This type of attack aims to camouflage, replay, illusion, and tamper with data to cause chaos and confuse the movement of the regime [4].

III. DDoS Attacks Detection

Several studies and solutions have been provided by researchers in the same study area in this part, and the goal of the article, as well as the research summary, such follows: In the IoV network system setting, high performance is challenging to deliver. This suggests using the Double Deep Q-learning Network (DDQN) model. Overestimation as a Vehicle Internet is prevented. In actual complicated settings, it can deliver higher-quality network services and guarantee improved computing and processing speed. The IoVs are intelligent transport, internet is a new application of the Internet. This research offered several innovative and practical solutions in this area. The algorithm relies in its work on calculating the discharge based on the DDQN network model and then the network tasks are allocated using asynchronous processing technology [8]. The use of wireless communications between vehicle nodes and DR infrastructure makes them vulnerable to various types of attacks. In this regard, ML and its variants are gaining popularity for detecting attacks and dealing with various kinds of security issues in vehicle communications. The research also explains the basics of vehicle networks and the types of communication related to them and how to find solutions using machine learning algorithms [6]. This research focuses on applying machine learning to gather data on vehicles along a GPS route and using the Gaussian process to anticipate traffic based on three groups: training and forecasting groups, bandits, and other variables. Additionally, traffic is forecast for the present and the future, and shortly, the average speed of cars during these times is evaluated [9], [3]. The development of autonomous intelligent cars can help solve transportation problems. The IoT has developed into an advanced and intelligent system called the IoVs, but it is still vulnerable to assaults from this study. To identify dangers. K fold the study discovered that the KNN-CART algorithm delivers the greatest accuracy, with respective values of 99.79% and 99.79% [10]. The Social IoT (SIoT) is the level of enabling awareness where it permits things to interact with one another. Social IoV (SIoV) will transform the automotive industry. The scalability of relying on online technologies is the main topic of this research. It is important to concentrate on the class structure and the function of each system entity while taking into consideration the dynamic nature of the study of SIoV's structure and emphasizing the unique use cases [11].

A. *Machine Learning-based Models*

Since ML was first used as a self-learning method for checkers in 1959, it has been widely used in all areas of the network to improve work performance. The typical model of machine learning consists of three stages:

- The training stage, where the advantages are extracted from the initial data.
- The testing stage, where a new set of data is tested based on the educational experience gained in the training phase by the ML model.
- The prediction stage, where the efficiency of the ML model's work is evaluated based on quality measures.
- ML shows outstanding results in the field of detecting anomalies due to its ability to learn patterns and behavior. Thus, it is the best solution to distinguish deviant from normal behavior, classify attacks, and discover their types.

ML based DoS/DDoS security modeling is shown in Fig. 1:

B. *Machine Learning Models for IoV Security*

- Supervised Learning: It is necessary to assign a value for the input and name a corresponding name for each input of the dataset through the relationship between the input models and the naming of the training group. The algorithm assigns newly acquired samples of test data and applies them to secure vehicle networks. Supervised training is classified as classification and regression, which is one category of popular classification models used in vehicle systems: KNN, DT, Naive Bayes (NB), SVM, RF, and LR models. Logistic regression and random forest models are applied in vehicle networks in applications such as driver fingerprints and types of misconduct.
- Unsupervised Learning: It consists of input values only in their training set and no labels for the dataset. Finding hidden patterns of data focuses on unclassified information. The algorithms used are more efficient and faster in data processing in aggregation applications. The most common assembly mechanisms in vehicle networks include k-means clustering, Hidden Markov Model (HMM), and NN [12].

IV. Proposed Models

In IoV, vehicles can connect and communicate through Vehicle-to-Road (V2R) communication, Vehicle-to-Infrastructure (V2I) communication, as well as communication with sensors Vehicle-to-Sensor (V2S), and Vehicle-to-Vehicle (V2V) communication. All of these communications take place through the wireless network. Of course, all of these communications must have a high level of protection to preserve privacy while continuing to improve it. Current network security technologies and products, such as network firewalls, intrusion detection systems, intrusion prevention systems, web firewalls, and other security devices, are used to enhance security. The user shares much information such as location, as well as many behavioral patterns and some involuntary information such as pedestrian images and private property. This information may be subject to violation, which raises concerns, and this problem cannot be solved by reducing the sharing of information but rather by finding solutions that make it trustworthy. This part will go through the methodology that depends on detecting attacks and penetrations to take urgent measures to protect the IoVs and maintain the privacy of information by monitoring the packets that pass through the IoV network and taking proactive measures to prevent these attacks to maintain a safe communication environment and achieve security requirements [12]. Our proposed model is shown as in Fig. 2.

A. *Details of the Research Methodology*

In this part, we learn how the effectiveness of the security model, as the study was based on the efficiency of the proposed model in detecting security attacks. The CICDDoS2019 dataset with ML machine learning models to detect the ability to detect a DDoS attack [13]. We analyzed the results of DDoS attacks through the machine learning model, which goes through three stages: the training stage, where features are extracted from the raw data, then the testing stage by ML models, where

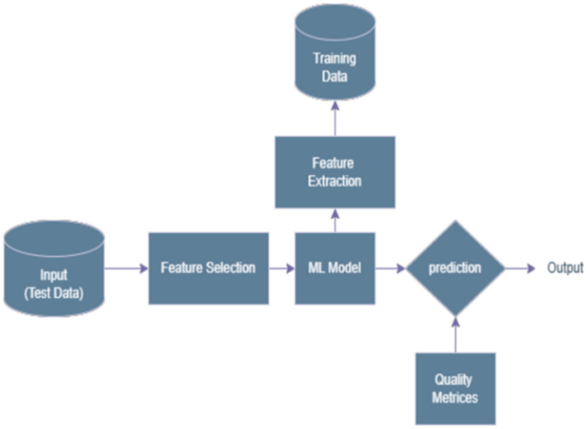

Fig. 2. The proposed method flowchart.

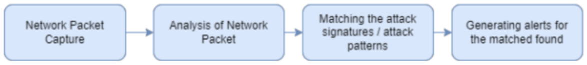
the dataset acquired during the training stage is tested, and the last stage is prediction, where the efficiency of the ML model is evaluated. Algorithm 1 shows the characteristics of the dataset used [14], [15]. Data preprocessing before building the ML model plays an important role in the accuracy of the machine learning models. The features were reduced from 80 to 47 using chi2, which further reduced the test time while Benign and DDoS attacks (UDPSYN) were replaced by [0.1] respectively. From a balancing act, a K-fold where k=5 was used to evaluate and compare ML models [16].

B. Intrusion Detection System (IDS)

IDS intrusion detection systems must be continuously updated to prevent attacks that develop daily. Some algorithms work well with some attacks and perform poorly with others. An ML-based IDS system can extract complex behavioral attributes that can be improved and also include dataset preprocessing [17] as in Fig. 3.



Network Packet Capture
Analysis of Network Packet
Matching the attack signatures / attack patterns
Generating alerts for the matched found

Fig. 3. Architecture of IDS.

There are two problems related to IDS:

- The high rate of false alarms, which are triggered by warnings for unlimited violations and many violations that have not yet been identified.
- New attacks are not easily detected, thus increasing the interest in using ML.
